The general approach for each layer followed this example: The total amount of disturbance for each mortality source was calculated for all of Canada (e.g. km of roads or km^2 of oil and gas disturbance). Grid tiles overlapping that mortality source were identified. For instance, if 137 grid tiles had oil and gas activity, the total area of oil and gas disturbance was taken from the previous calculation and the proportion of disturbance in each tile was derived by simple division. The proportional kill for that entire mortality source was then assigned to each applicable tile. If a single tile had 5% of the total national disturbance, the total kill for oil and gas was multiplied by 0.05 and assigned to that tile. Therefore the units for each mortality source are in birds or nests taken as per the original research paper. Standardized values from our manuscript Table 3 were not used because they were not calculated at the same geographic level of specificity (e.g. kills for agriculture were converted nationally, not at the BCR level).

Grid totals (number of kills) were created by summing the values for the eight mortality sources above. Each map was coloured in a colour ramp of 10 classes and the natural breaks (Jenks) classification method was applied for all datasets (http://en.wikipedia.org/wiki/Jenks_natural_breaks_optimization). Note that this classifier does not produce equal width classes, but does optimize the splits for presentation.

As noted generally in the manuscript text, the following caveats apply:

- The map is a gross approximation only and we acknowledge that none of the sources/sectors above would be expected to have kill exactly proportional to their intensity. Technically we consider it to be a map of potential risk that remains unrealized until the sources of mortality interact with birds and result in deaths.

- Actual kill in any given tile would depend on many factors that cannot be mapped with currently available national data: the density of birds, the specific interaction of the source/sector with those birds in each environment (i.e. traffic volume, height of roadside verges, local features attracting birds), the seasonal timing of the activity, and even local weather conditions in any given year.
- In certain cases, such as forestry, a realistic calculation should be based on the location of actual cutting in Canada rather than the entire area available for cutting. This would be similar for farming; the location and spatially explicit footprint of each crop or farm type would ideally be known nationally. Such data are not available.
- In spite of these caveats, it remains self-evident that kills occur where the source/sector operates and, as a generalization, more activity by a given source/sector would result in some incremental increase in kill. We have constrained the scale of the map and smoothed the final product to minimize the perceived precision of the mapping classes.

Each section below contains the data source for each source of mortality, how we derived the maps and sector-specific maps that are not presented in the main paper.

Bird-vehicle Collisions

- Source: GeoBase website (http://www.geobase.ca/) National Roads Database, 2011.
- Spatial Reference: NAD83CSRS (North American Datum 1983 in Canadian Spatial Reference System)
- Ellipsoid Name: GRS80 (Geodetic Reference System 1980)
- Total kill figure used: Kills per km/day of road, by ecotype, from Table 3 in Bishop and Brogan 2013.

The National Road Network (NRN) is produced, updated, and distributed (with the support of GeoConnections) through collaborative agreements between Natural Resources Canada, Statistics Canada, and the provincial and territorial governments. A detailed summary of the product is here:

http://www.geobase.ca/geobase/en/data/nrn/description.html

Methodology:

A roads layer was created from the NRN which displayed only 1 and 2 lane paved roads that occurred outside of urban areas using a ‘select by attributes’ query and did not contain Ramp features. A ‘create layer from selected features’ was then used to create a new layer containing only these selected features. The query used to extract this data was: ("NBRLANES" <3 AND ("PAVSTATUS" = '1Paved' OR "PAVSTATUS" = '2Paved' OR "PAVSTATUS" = 'Paved') AND "ROADCLASS" <> 'Ramp').

Roads were separated by ecozone type following the methods in Bishop and Brogan (2013); ecozone types consisted of: Broadleaf and Mixed Forest (classified as one ecozone), Coniferous High Volume (1%), Coniferous Low Volume (99%), Cropland, 90% Rangeland Area, 10% Rangeland Area and Wetlands. Each ecozone type was assigned a kill value for the number of birds killed per kilometre of road based on Table 3 in Bishop and Brogan (2013).

Roads were separated into each individual 50 km tile by using the 'Intersect' tool**.** The intersect output contained numerous road segments and types by tile; each ecotype total was multiplied by the value for birds killed per kilometre per day corresponding to the ecotype classification of that segment and then multiplied by the number of days (122) and adjusted for scavenging by multiplying by 2.97 (Table 3, Bishop and Brogan 2013).

The 'merge' tool was then used to join all 7 ecozone types together with all of their final road values for the number of birds killed by unique tile ID. The 'Dissolve' tool was then run to dissolve all roads by Tile ID and sum the total number of birds killed annually for all 7 ecozones.

The result of the road analysis is shown in Fig. A4.1.

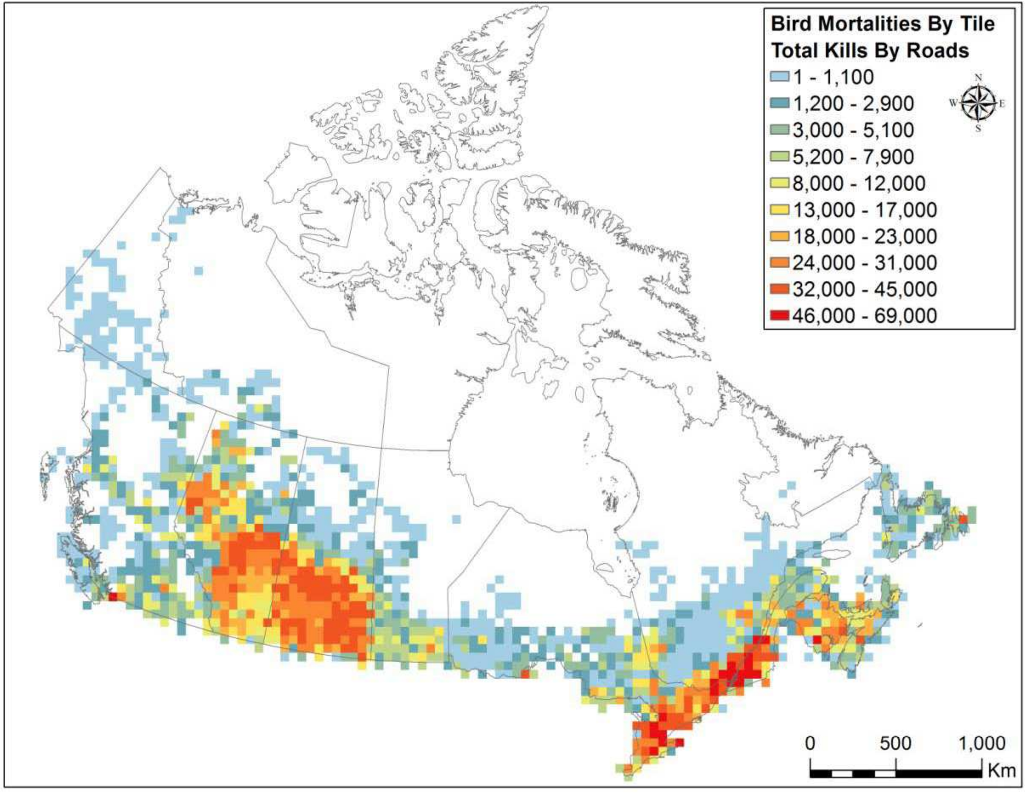

Fig. A4.1 – Approximated distribution of bird-vehicle collisions in Canada on road types considered by Bishop and Brogan (2013).

Communication Towers

- Source: NAVCAN database of tower locations. License paid for by Environment Canada for EC use as specified in agreement. Substantial corrections on the original data were performed by Beau MacDonald (The Urban Wildlands Group, Los Angeles, CA, USA) for use in Longcore et al. (2012).
- Spatial Reference: n/a
- Ellipsoid Name: n/a
- Total kill figure used: ~221,000 (Table 7, Longcore et al. 2012).

Methodology

NavCan tower data were provided in a proofread and cleaned format. The equation from Fig. 3 of Longcore et al. (2012) was used to calculate predicted tower mortality for each tower. Longcore et al. (2012) used a probability-based reduction of totals at the BCR level to account for towers that were guyed or not and steadily lit or not. We applied a BCR-specific static adjustment to each tower kill value such that our BCR total matched those from Longcore et al (2012) because we calculated mortality at the individual tower level. Only towers > 60m tall were considered in our analysis, the same restriction used by Longcore et al. (2012).

The 50 × 50 km tile grid was overlaid with the communications tower point layer and a spatial join was performed to link each point to the proper tile that it fell within. The Dissolve tool was then run to sum the number of kills by tile ID using the statistics function.

The results of our communication towers analysis is shown in Fig. A4.2

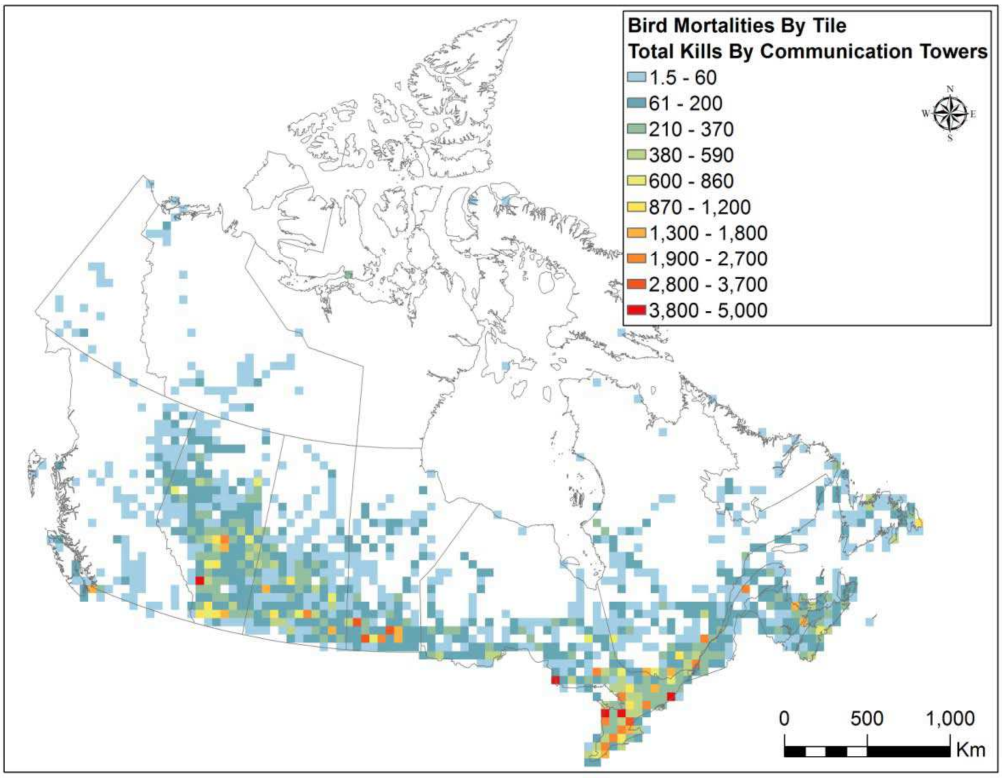

Fig. A4.2 – Approximated distribution of kills from birds colliding with communication towers >60 m in Canada.

Terrestrial Oil and Gas (wells, seismic lines, pipelines)

Total kill figures are from the mean value column of Table 3 (number of nests) in Van Wilgenburg et al. (2013). Those data are split in each province into boreal areas and prairie areas.

Manitoba

- Source: Manitoba Innovation, Energy and Mines http://www.gov.mb.ca/iem/petroleum/gis/index.html
- Spatial Reference: North American 1983 CSRS UTM Zone 14N
- Ellipsoid Name: GRS 80
- Total kill figure used: Boreal: 211, Prairie: 92

Metadata are not provided with the wells file on the above noted website.

The data was displayed by township (6 mile by 6 mile square area polygons) which contained the number of wells within each township.

Saskatchewan

- Source: Saskatchewan Energy and Resources oil and gas information viewer, http://www.infomaps.gov.sk.ca/website/SIR_Oil_And_Gas_Wells/viewer.htm
- Spatial Reference: North American 1983 UTM Zone 13N
- Ellipsoid Name: GRS 80
- Total kill figure used: Boreal: 284, Prairie: 2602

Metadata are available at https://www.geosask.ca by entering the Spatial Gallery, searching for the data layer “wells” and using the metadata viewer.

The data was displayed by township (6mile by 6mile squares) which contained the number of wells within each township.

Alberta

- Source: Energy Resources Conservation Board (http://www.ercb.ca/) data subscription for well data to Environment Canada.
- Spatial Reference: North American 1983 UTM Zone 10N
- Ellipsoid Name: GRS 80
- Total kill figure used: Boreal: 1125, Prairie: 5677

The data were in point format and each point contained a value for the number of wells at that specific location.

Metadata are provided via Environment Canada’s digital subscription (i.e. not on the ERCB website) and are available by contacting the authors.

British Columbia

- Source: British Columbia Oil and Gas Commission, ftp://www.bcogc.ca/outgoing/OGC_Data/Wells/
- Spatial Reference: BC Albers, NAD83
- Ellipsoid Name: GRS 80
- Total kill figure used: Boreal: 1125, Prairie: n/a

In addition to the short metadata associated with the above link, more information on the data is available here:
ftp://www.bcogc.ca/outgoing/OGC_Data/ePASS_Documents/ePASS_Standards_Requirements.pdf

Methodology

We restricted our analysis to the area covered by Van Wilgenburg et al. (2013). Raw well data for Manitoba and Saskatchewan were processed by S. Van Wilgenburg and overlaid with the official township grid for those provinces. The township grid (polygon data) for Manitoba and Saskatchewan were placed into one dataset by using the 'Merge' tool to place all townships into one dataset (containing the number of wells by township).

No township data was available without an associated fee for British Columbia and Alberta so a 6 × 6 mile tiled grid was created using the Fishnet tool in order to represent the size of townships within Alberta and British Columbia (Taylor 1975). The 6 × 6 mile tiled grid was then overlaid with the point layer that was provided for AB and BC in order to assign a well count value to each township grid using a spatial join. The output was a polygon vector that contained numerous point data (many points) to one township. The dissolve tool was used to sum up the total count value of wells by township. The township polygon for AB and BC was then added to the MB and SK township dataset using the 'Merge' tool.

Using the Bird Conservation Regions (BCR) layer (http://www.nabci-us.org/bcrs.htm) the townships were classified as Boreal or Prairie based on which larger proportion of the township fell within the specified BCR (11 for prairie, 6 for boreal).

We calculated the area in each township disturbed by seismic line and pipelines using the following formulas from Appendix 1 of Van Wilgenburg et al. (2013) based on the well count value.

- The percent of township disturbed by seismic lines in the Boreal Plain Ecozone can be estimated as: $\% = (0.974 + 0.807*\log(\text{wells}))^2$
- The percent of a township disturbed by seismic lines in the Grassland Natural Region (Prairie) can be estimated as: $\% = (0.430 + 0.006*\log(\text{wells}))^2$
- The percent of a township disturbed by pipeline right-of-ways in the Boreal Plain Ecozone can be estimated as: $\% = (0.699 + 1.866*\log(\text{wells}))^2$
- The percent of a township disturbed by pipeline right-of ways in the Grassland Natural Region (Prairie) can be estimated as: $\% = (0.655 + 1.811*\log(\text{wells}))^2$

We had to convert well count to well area within each township. A value of 20,000 m^2 (2 ha) was assigned to each well based on written advice from the Canadian Association of Petroleum Producers as used in Van Wilgenburg et al. (2013). The sum of the area disturbance by seismic lines, pipelines and the total well areas by township were summed to obtain the overall area of disturbance by township.

Townships were intersected with the 50 × 50 km tile grid. An area calculation was done on the divided (intersected) townships in order to determine the proportion of that township that fell within each tile. The proportion value was then multiplied by the overall area of disturbance by township (sum of Seismic, Pipeline and Well area) in order to determine the total area of disturbance within each tile. The 'Dissolve' tool was run to dissolve all townships by tile and the statistics field was used to 'SUM' the area of disturbance values for each portion of the townships that fell within each individual tile.

The BCR layer was then overlaid with the 50 × 50 km tiled disturbance area layer and each tile was reclassified as 'Boreal' or 'Prairie'. Whichever larger portion (>50%) of the cell fell within the specified BCR then that tile was classified as that region.

The proportion value for each tile was calculated from the final disturbance value depending on which province and part of a province (boreal or prairie) the tile fell into. Total disturbance value by each provincial region was calculated. In areas where tiles overlapped with provinces and/or prairie/boreal regions, the proportion of each had to be calculated using the area field and multiplying those proportions based off of the total tile area of 2500 km^2; in all other cases the tile had a value of 100% for the province/region intersect.

The proportion of each 50 × 50 km tile disturbed were then multiplied by the kill values listed above for each of the 7 intersections of province and habitat. Calculations were all performed within the Field Calculator.

The result of our oil and gas analysis is shown in Fig. A4.3.

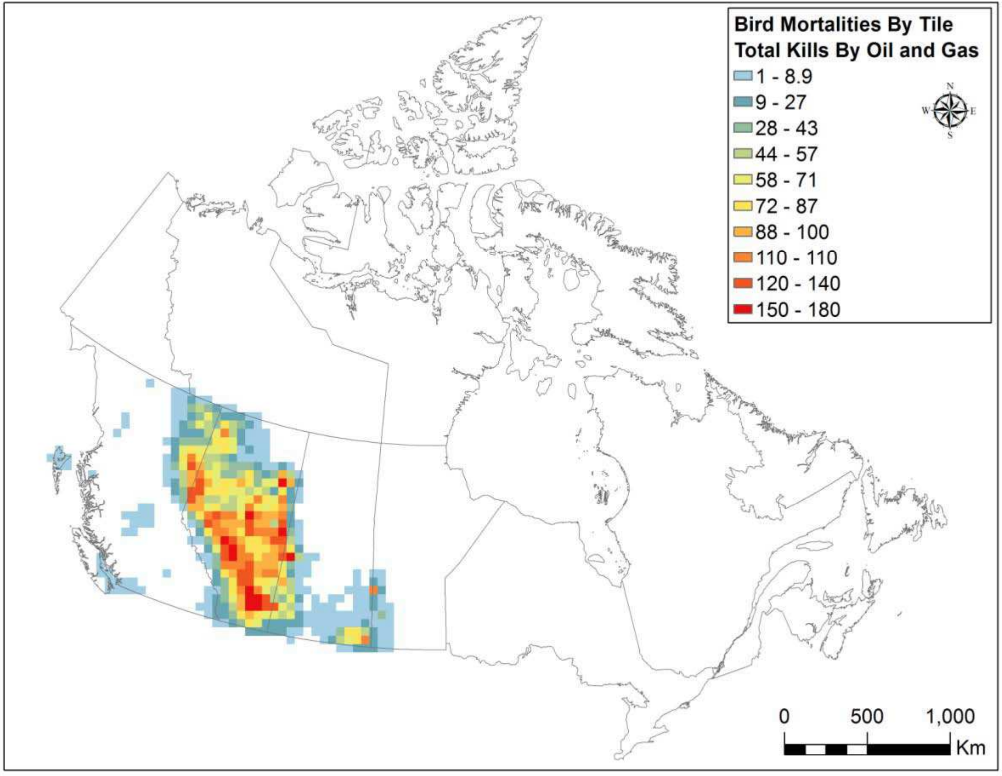

Fig. A4.3 – Approximated distribution of nests destroyed from the oil and gas sector in the western Canadian sedimentary basin as enumerated by Van Wilgenburg et al. (2013).

Forestry

- Source: Global Forest Watch Canada data warehouse (http://datawarehouse.globalforestwatch.ca/), Canadian Commercial Forest Tenures Map (last updated on January 30th, 2004)
- Spatial Reference: Lambert Conformal Conic
- Ellipsoid Name: Clarke 1866
- Total kill figures (nests) from Hobson et al. (2013, Table 6) by averaging the low PIF estimate and the high BAM estimate (see Table A4.1)

A brief description of the data from Global Forest Watch Canada is: "A compilation of the basic forest tenure/concession data from all of the provinces. [It] includes companies in order of allowable annual cut (where applicable/available). Tenures/concession polygons will contain areas restricted to logging and other resources extraction activities by protected areas legislation and by other legislative and policy restrictions. We attempted to include only crown lands and exclude all private lands where the data was available (e.g., New Brunswick), but other jurisdictions may have inadvertently included private lands."

Metadata: http://www.globalforestwatch.ca/data/tenure_spatial/CANADA/canada_tenures.txt

Table A4.1 – Estimated nests destroyed by forestry from Hobson et al. (2013).

Province	Estimated nests destroyed
BC	387,926
AB	62,210
SK	15,316
MB	6039
ON	255,832
QC	372,680
NB	126,316
NS	88,924
PEI	6938
NF	15,576
NT, YK, NU	0 (no forest tenure map data available, no tenures, or no forestry in the region)

Methodology

The forestry tenure data (Fig. A4.4) was dissolved and overlaid with the 50 × 50 km tile grid and clipped by tile. Tiles were broken down by province and the proportion of forestry tenure that occurred within each tile, within a province was determined. The proportion of forestry by tile by province was then multiplied by the kill values (above) by province in order to determine the total kills by tile. This value represents the number of nests destroyed by tile.

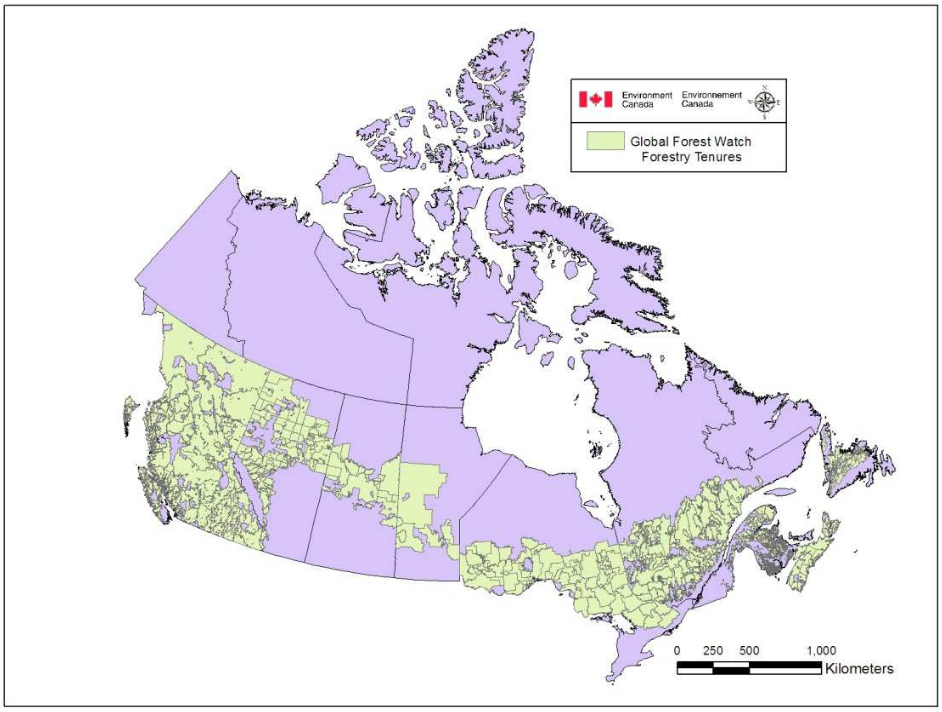

Fig. A4.4: Forestry tenures across Canada as mapped by Global Forest Watch. Data are current to 2004.

The result of our forestry analysis is shown in Fig. A4.5.

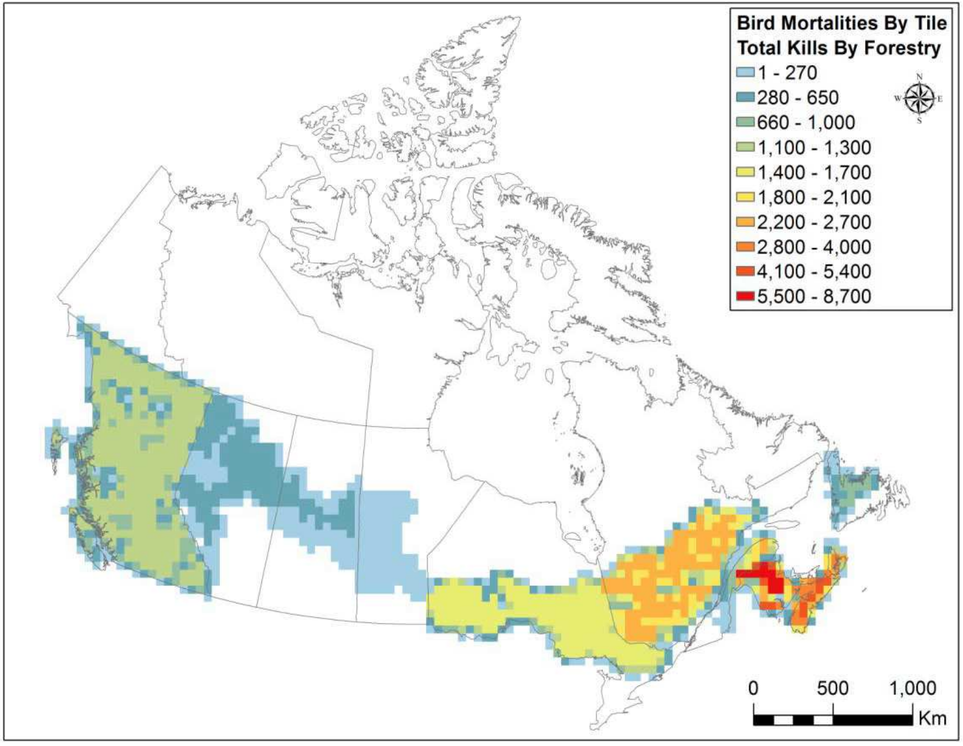

Fig. A4.5 - Approximated distribution of nests destroyed from the forestry sector in Canada as enumerated by Hobson et al. (2013).

Agriculture

- Source: Statisics Canada 2006 Agriculture Census (http://www.statcan.gc.ca/ca-ra2006/index-eng.htm) tabular data (no shapefiles)
- Spatial Reference: n/a

Agriculture Census information: http://www.statcan.gc.ca/ca-ra2006/about-apropos-eng.htm

Methodology

Tabular agricultural data from the 2006 Agricultural Census was manually combined with the Canadian Census Subdivision (CD) data (http://www12.statcan.gc.ca/census-recensement/2011/geo/bound-limit/bound-limit-2011-eng.cfm). The number of each farm types that were present within that CD was entered from the Agriculture Census Data tables.

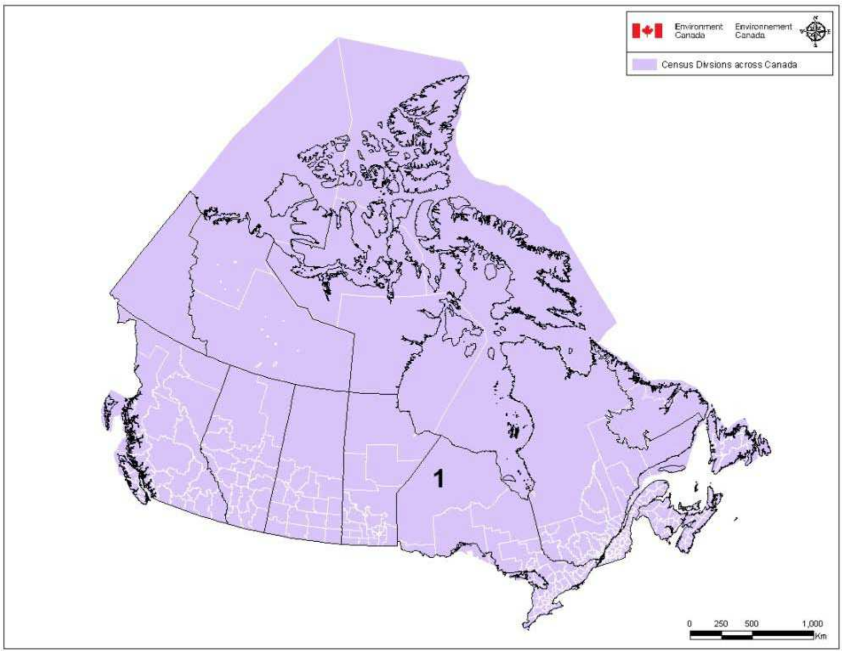

Fig. A4.6 – Census divisions (CDs) of Canada from Statistics Canada. Note that the northern portion of most provinces and all of the territories have very large divisions. The CD labeled with a '1' is Kenora and is discussed in the text as an example of how the large divisions were problematic.

Below is the list of farm types that have been identified in the Agriculture Census Data. The number in front of each is how we classified them into the aggregate groups following the main list:

2 Hay Farming
3 Fruit and vegetable combination farming
3 All other miscellaneous crop farming
3 Floriculture Production
3 Tobacco Farming
3 Other food crops grown under cover
5 Nursery and tree production
3 Fruit and tree nut farming
3 Mushroom Production
6 Livestock combination farming
4 All other miscellaneous animal production
4 Horse and other equine production
4 Fur bearing animal and rabbit production
6 Goat Farming
5 Apiculture
4 Other poultry production
6 Sheep farming
4 Poultry Hatcheries
3 Potato Farming
3 Other Vegetables (except potatoes) and melon farming
1 Corn farming
1 Other grain farming
1 Dry pea and bean farming
1 Wheat Farming
1 Soybean Farming
1 Oilseed (except soybean) farming
4 Combination poultry and egg production
4 Broiler and other meat type chicken production
4 Turkey Production
4 Hog Pig Farming
4 Chicken Egg Production
4 Dairy Cattle Milk Production
6 Beef Cattle Ranching Farming Feedlots

Aggregated Groups:

1 – annual grain type cropping
2 – hay farming
3 – fruit, vegetable, other miscellaneous farming
4 – animal farming, not big grazers
5 – farming without regular harvesting (bees, tree growing)
6 – livestock/grazers

Tews et al. (2013) only calculated mortality estimates for the first 3 groups above. Mortality from grazing was calculated by Bleho et al. (2013) separately and is not mapped.

Methodology

Since there were no geospatial files available with this agricultural data, the CD's geospatial data was downloaded from Statistics Canada in order to link the unique CD ID's with the CD ID's from the 2006 Census of Agriculture dataset. The datasets were merged by using the 'join' operation based on the CD Unique ID's.

CDs in Canada are not equally sized (Fig. A4.6), nor particularly representative of areas of the country where agriculture occurs (Fig. A4.7). This creates a problem as the number and type of farms is only summarized at the CD level. For large CDs with very little agriculture (such as Kenora in Fig. A4.6), we initially had uniformly distributed the farm count across all of our 50 × 50 km tiles covering the entire CD. The result of that process was that it appeared as though hay farming occurred everywhere at a low level in Ontario, from the US border right to James Bay.

To fix this problem we constrained our 50 × 50 km tile grid by the extent of agriculture land in Canada. The tile layer was intersected with the agriculture lands layer (Fig. A4.7), producing a much smaller potential tile grid in Canada. This is identical to the process used to display forestry in Canada where our tile grid was constrained by the forestry tenure layer. The result is that large and/or northern CDs like Kenora now only had grid tiles where agriculture occurs (in this case at the extreme southern end).

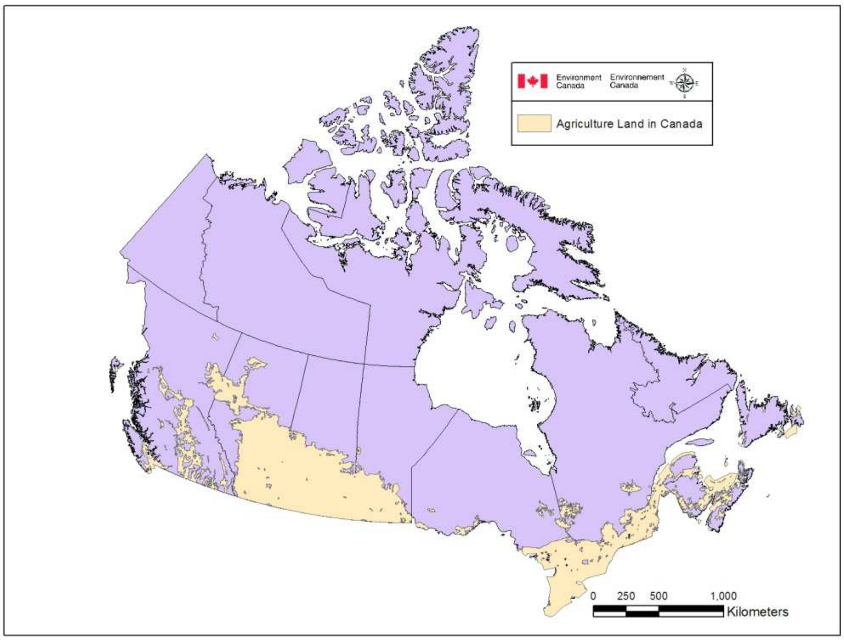

Fig. A4.7 – Distribution of agricultural land in Canada. Data provided by T. Rounce, Agriculture and Agri-Food Canada. Original derivation is from the Census of Agriculture interpolated variable called 'PERAGR' which is the percent of agriculture within a Soil Landscape of Canada (v3.1) polygon.

Agricultural data was displayed by CD across Canada. In order to determine the total percentage of each farm type that occurs by tile across Canada we did the following:

- Census Divisions were intersected to each 50 × 50 km tile. The sub-area for each divided CD (CDs crossing tile boundaries) was calculated and the area value was then used to calculate the percentage of each CD's that fell within each tile (assumes population is homogenously distributed in each CD, likely not true).
- The number of each farm type within each CD (Grain, Haying, Vegetables) was multiplied by the proportion of each CD that fell within each unique tile ID in order to obtain the number of farms within each tile for each farm type.
    - The 'Dissolve' tool was then used so that all CD's were dissolved by each 50 × 50 km tile and the statistics field was used to 'SUM' the number of farms within each tile. This was done separately for each of the 3 farm types.
    - Ideally we need the area of each farm type in each CD. However, Statistics Canada does not provide the area associated with each farm or in aggregate, so all we have is a count of farms by type in each CD.
- Equally distribute the quotient to each tile.

A map of Bird Conservation Regions (BCRs) was then overlaid on the tile grid with all the farming data. The two layers were intersected and each tile was assigned to its respective BCR (overlap cases were put into the BCR which contained the greater proportion of the tile area). The total number of farms of each type for all tiles in each BCR was calculated and the proportion in each tile was then derived.

Kills by farm type and BCR (Table A4.2) were then multiplied by the proportion of that farm type in that BCR for each 50 × 50 km tile. This represents the total nestlings or eggs killed per tile.

The results of our agriculture analysis are shown in Fig. A4.8: Grain Cropping, Fig. A4.9: Haying, and Fig. A4.10: Vegetable Cropping.

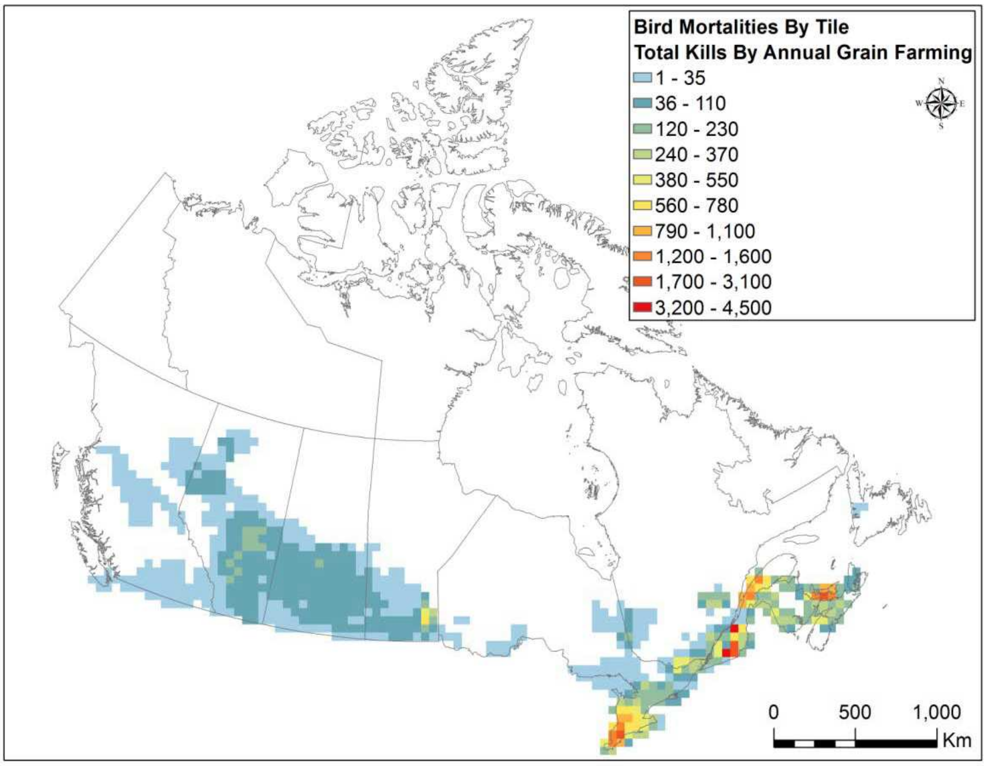

Fig. A4.8 – Approximated distribution of nestlings and eggs destroyed from the grain cropping in Canada as enumerated by Tews et al. (2013).

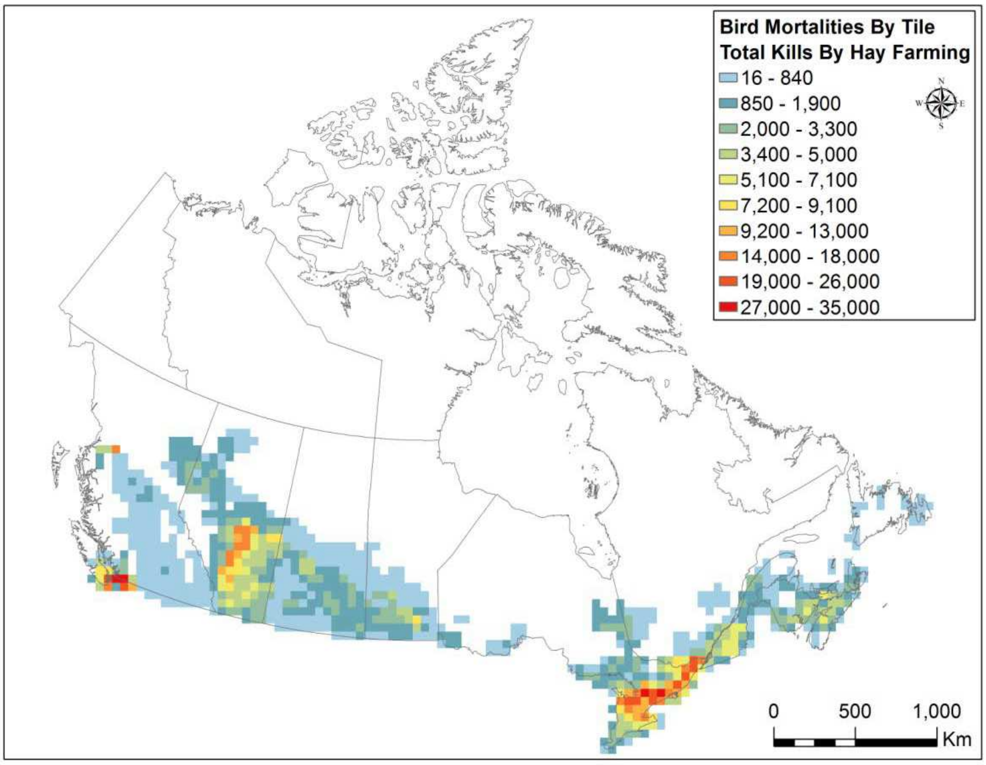

Fig. A4.9 - Approximated distribution of nestlings and eggs destroyed from the haying in Canada as enumerated by Tews et al. (2013).

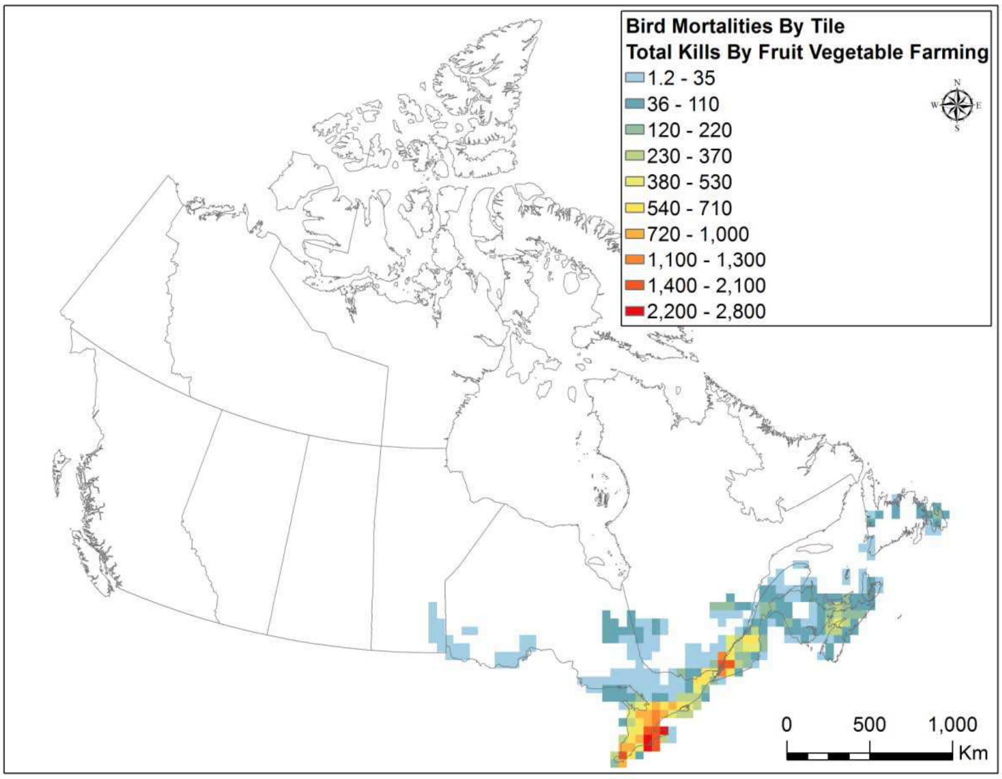

Fig. A4.10 – Approximated distribution of nestlings and eggs destroyed from the vegetable (and fruit) cropping in Canada as enumerated by Tews et al. (2013). Agriculture Census data had entries fruit and vegetable farms in western Canada (as expected), but the species analyzed and results from Tews et al.

(2013) had zero deaths for the western BCRs (such as BCRs 5 and 9 covering the lower mainland of BC).

Cats and Buildings (based on Population Density)

- Source: 2006 Census of Human Population, Statistics Canada (http://www12.statcan.gc.ca/census-recensement/2006/index-eng.cfm)
- Spatial Reference: n/a
- Ellipsoid Name: n/a
- Total kill figure used: Cats: 204 million (median value, Blancher 2013); Buildings: 24,900,000 (total average values from Table 5 in Machtans et al. (2013).

The 2006 Census Population Density data for Canada was used to display the data by Census Division (CD). The Census Division data was not spatially represented so the geospatial file containing the Census Divisions for Canada were also obtained from Statistics Canada in order to acquire the desired results.

Methodology

Human population density was used as a proxy for the spatial distribution of both cats and buildings across Canada. We provide rationale below for using population data as the proxy for the two sources of mortality.

Cats: Per capita pet ownership in Canada was tabulated by Leger Marketing (http://www.legermarketing.com/documents/SPCLM/020617eng.pdf) and varied somewhat across Canada. In the absence of spatial data on pet ownership however, we calculated ≤ 2% difference between the proportion of cats per province (number of households × % cat ownership) and the % of total human population per province (Table A4.3). Although the results are autocorrelated from using population to calculate cats, this exercise demonstrates that the regional variation in cat ownership rates is a trivial deviation from simply approximating ownership by population. We recognize that if the number of cats per household varies radically across the country that it would introduce another inaccuracy into our map (Perrin [2009] indicates an average of 1.76 cats per owner). We expected unowned cat numbers to be associated with owned cats in some unknown, but constant ratio (fewer people in rural settings, fewer pet cats total, and fewer feral cats, with the opposite in cities). We did not explicitly extrapolate the unowned cats into the totals below. Because we assumed a constant ratio between the two types, and allocated the total kill of all cats to the proportional representation of population, no mapping differences would appear from calculating unowned cats in the table below.

Table A4.3: Comparison of geographic distribution of population by province and calculated owned cats per province.

Prov	Population (2011)	Proportional Population	People/ Household	2002 Cats Ownership Rate	Number of Owned Cats	Proportional Cat Population	Difference (% Human - %Cat)
BC	4,400,057	13%	2.5	32%	991,245	15%	-2%
AB	3,645,257	11%	2.6	31%	764,943	11%	0%
SK	1,033,381	3%	2.4	21%	159,141	2%	1%

Prov	Population (2011)	Proportional Population	People/ Household	2002 Cats Ownership Rate	Number of Owned Cats	Proportional Cat Population	Difference (% Human - %Cat)
MB	1,208,268	4%	2.5	21%	178,630	3%	1%
ON	12,851,821	38%	2.6	28%	2,435,914	36%	2%
QC	8,080,550	24%	2.3	26%	1,607,678	24%	0%
NB	751,171	2%	2.4	37%	203,818	3%	-1%
NF	514,536	2%	2.5	37%	134,026	2%	0%
NS	921,727	3%	2.4	37%	250,095	4%	-1%
PEI	140,204	0%	2.5	37%	36,520	1%	0%
NT	41,462	0%					
NU	31,906	0%					
YT	33,897	0%					

Notes:

1. People/household is from 2006 Population Census, statistics Canada.
2. Average cat ownership rate was higher (about 36% compared to 31% here) in Perrin (2009) as cited by Blancher (2013), but we could not get updated geographic breakdowns of ownership rate and therefore used the 2002 figures from the Leger survey. Therefore the sum of the column "number of cats" is lower than the estimated number of pet cats given in Blancher (2013).

Buildings: The number of people per household in Canada varies little (2.3 - 2.6 persons per household for all major provinces [2006 Census data]), and since each household should be a unit represented in the analysis of Machtans et al. (2013), the proxy of population for buildings is gross (not 1:1), but suitable for broad scale mapping. This relationship would be confounded slightly since high rise apartments have many households in them and are technically counted in the high rise buildings section of Machtans et al. (2013). However, we did not break out the three categories of buildings separately in the mapping exercise so this confounding would be largely inconsequential. We did not have data to correlate the number of low-rise commercial buildings to population but assumed it was a linear relationship so proportional population could represent the kills from this class.

The number of tall buildings is highly correlated with log(population) in cities but is not completely log-linear (Fig. A4.11). We ignored both the logarithmic curve function and its inflection given that of the ~25M birds killed by buildings in Canada, only 1% in total is ascribed to tall buildings and slight adjustments for the proportion of buildings in each city in Canada in each 50 × 50 km tile would not be visible in the final map. While technically this would have been a better map of tall building density, Machtans et al. (2013) provides evidence that the number of buildings alone is a poor predictor of tall building bird-collision deaths (geography seems very important).

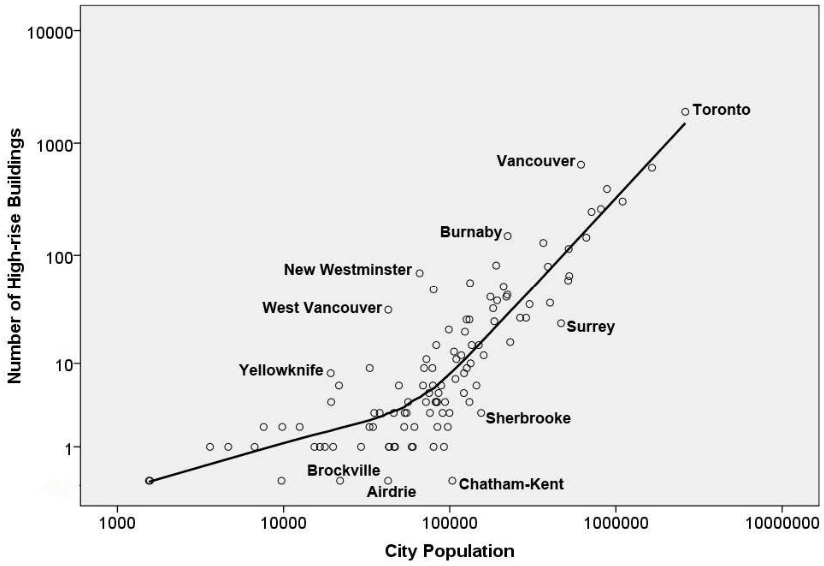

Fig. A4.11 – The relationship between city population and number of high-rise buildings in Canada. High-rise data from http://skyscraperpage.com/cities/?s=0&c=2&p=0&r=50&10=0

Population data were exported from Statistics Canada and merged together for all CD's in Canada. Tabular data were joined with the CD shapefile which contained the polygons for each CD. The join was performed based on the unique ID's from the CD's ID field. Using the 'Field Calculator', the area for each CD was calculated.

Census Divisions were intersected to each 50 × 50 km tile. The sub-area for each divided CD (CDs crossing tile boundaries) was calculated and the area value was then used to calculate the percentage of each CD's that fell within each tile (assumes population is homogenously distributed in each CD, likely not true). The result was multiplied by the 2006 Population Density for each unique CD based on the percentage of the CD's that fall within each individual tile.

Census Divisions were dissolved by each 50 × 50 km tile and population densities were summed. Proportion of the total national population in each 50 × 50 km tile was calculated.

Proportional population in each tile was multiplied by the kill values for cats and buildings separately to produce the two data layers. The problem with large census divisions explained in the Agriculture section was also encountered for the population layer. We arbitrarily removed all tiles with population densities of < 100 people per tile (0.04/km^2). We then reinserted only the tiles that contained communities.

The results of our analyses (Fig. A4.12: cats; Fig. A4.13: buildings) appear identical because the 10 colours chosen for each class are identical and the underlying population distribution is the same. Note the different estimate of take per tile in the legends however.

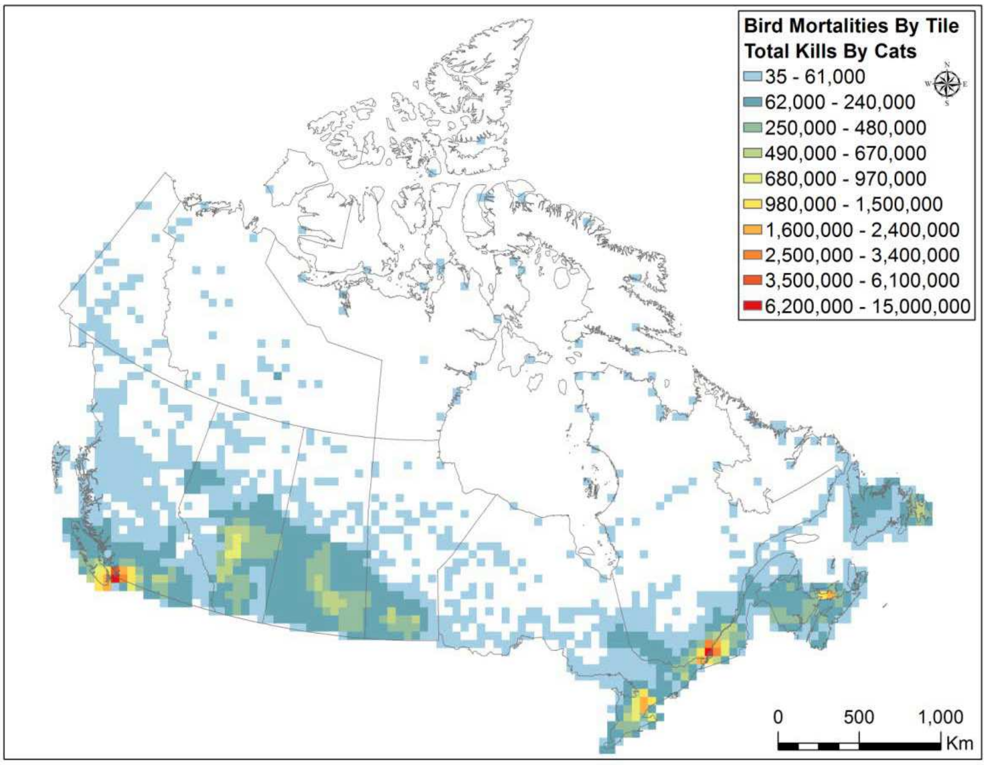

Fig. A4.12 –Approximated distribution of birds killed by cats in Canada from values in Blancher (2013).

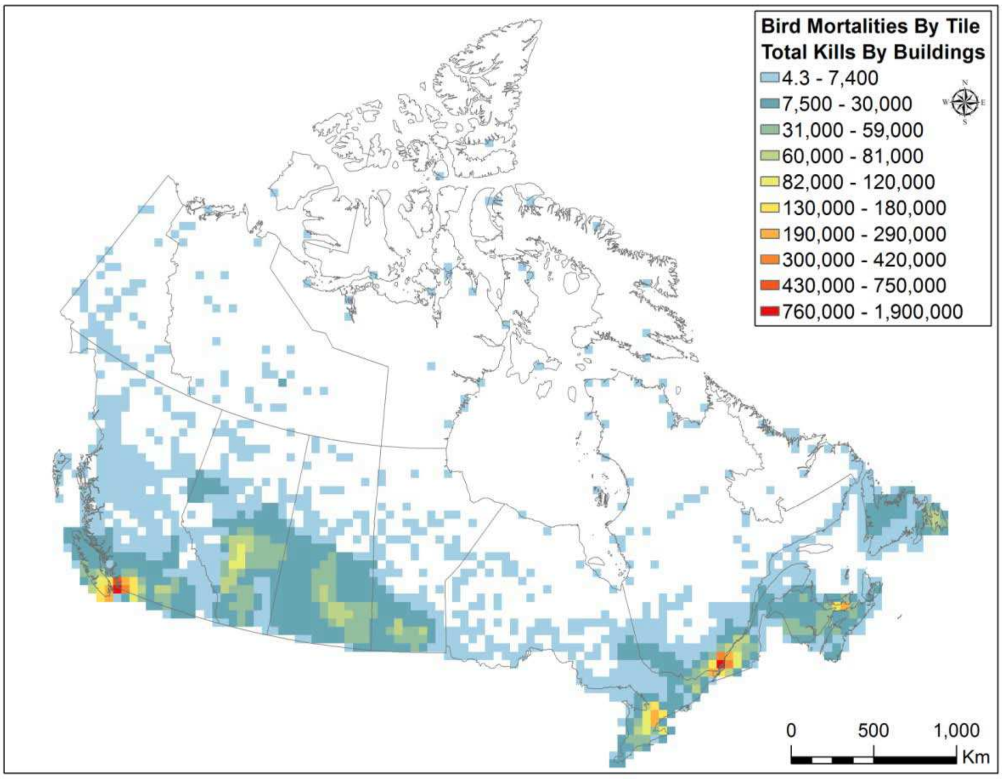

Fig. A4.13 – Approximated distribution of birds killed by colliding with windows in buildings in Canada from values in Machtans et al. (2013). Note that the legend values are different than in the similarly coloured Fig. A4.12.

Wind Power

- Source: Canadian Wind Energy Association (http://www.canwea.ca/farms/wind-farms_e.php) web table and on-line map
- Spatial Reference: n/a
- Ellipsoid Name: n/a
- Total kill figure used: 5.9 birds per turbine from Zimmerling et al. (2013).

We created our own point layer shapefile by deriving coordinates for each wind farm from the above noted source. We entered the provided data for each wind farm (number of turbines and type) in the attribute file.

Methodology

Each point in our wind farm layer (one wind farm) was assigned a total kills by multiplying the number of turbines at that facility by the average kills per turbine noted above. The 50 × 50 km tile grid was overlaid with the wind farm point layer and a spatial join was performed in order to assign a tile ID to each wind farm point location. The Dissolve tool was then run to sum all kills within each unique tile ID using the statistics filed within the dissolve tool.

The result of our analysis on wind farms is in Fig. A4.14.

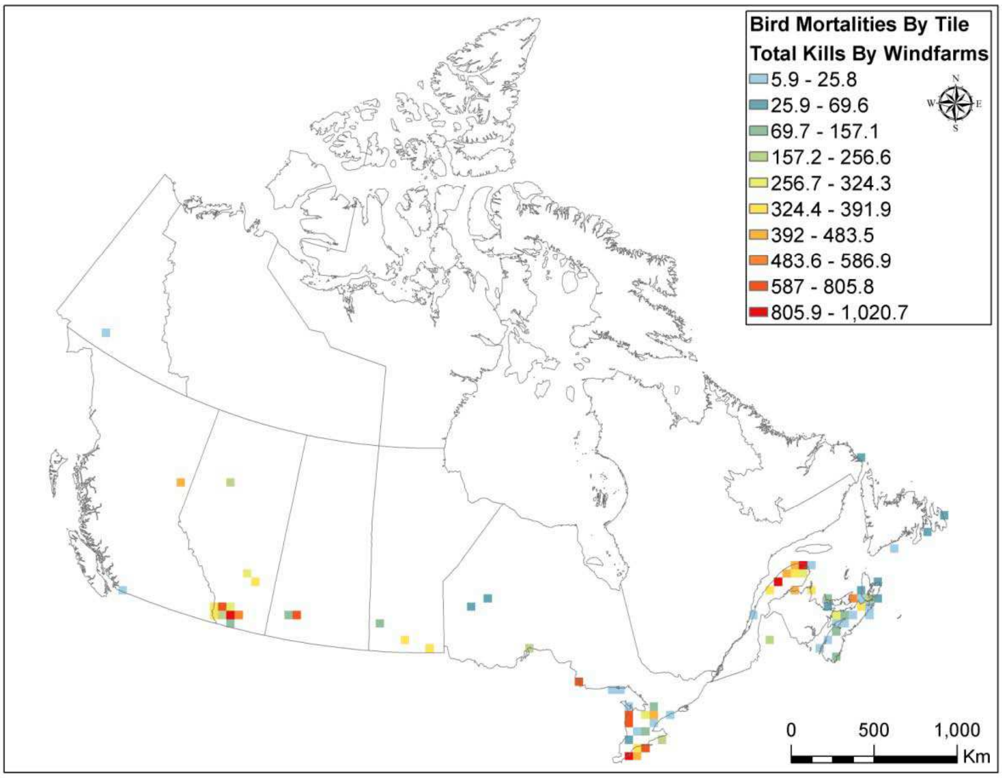

Fig. A4.14: Approximated distribution of kill of birds by wind farm operation in Canada based on average kill per turbine in Zimmerling et al. (2013).

Combined layers used in main paper

The final analysis involves summing all tile values for each of the specified mortality sources. Two maps were created. First, a map summing all layers was made. However, since so much kill in Canada is attributed to cats, bird-building collisions, and bird-vehicle collisions, a second map without these three sources was created.

The results of the summed layers for all mortality sources are shown in Fig. A4.15 and the results without the three sources noted above are in Fig. A4.16. Finally, the distribution of total mortality from only the top three sources (cats, bird-building collisions and bird-vehicle collisions) is presented in Fig. A4.17.

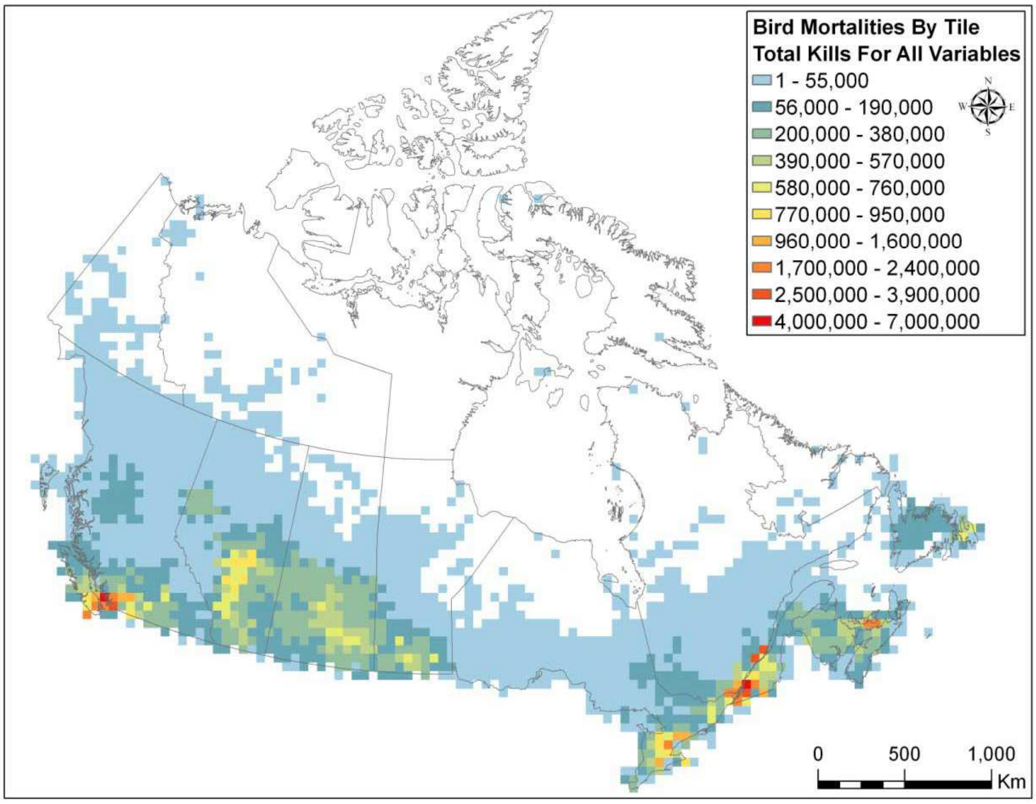

Fig. A4.15 – Approximated distribution of all bird mortalities across all sources considered.

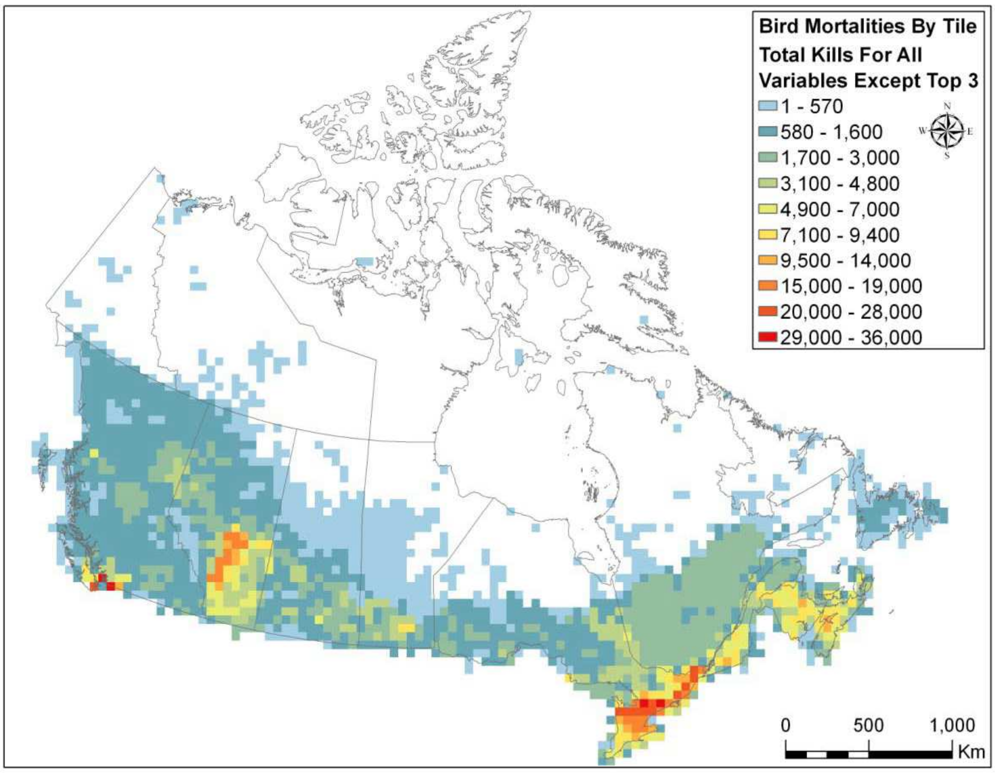

Fig. A4.16: Approximated distribution of all bird mortalities for all sources except cats, bird-building collisions and bird-vehicle collisions.

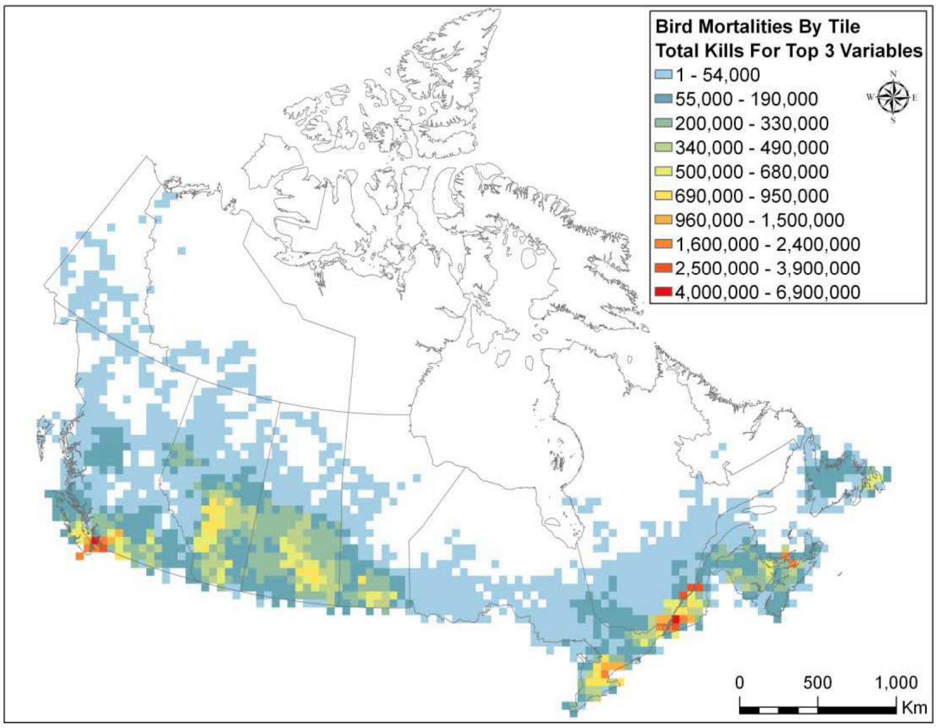

Fig. A4.17 – Approximated distribution of all bird mortalities from cats, bird-building collisions and bird-vehicle collisions only.

Avian and Wildlife Reporting Form

***** All Fields Must Be Filled Out. Do Not Leave Any Field Blank. *****

INCIDENT DETAILS

Observation Made During (circle one):

Evaporation Pond Monitoring / Scheduled Mortality Survey / [✓ Incidental]

Date: 6/28/2013 Observer: Eric German

Type of Incident (circle one): Injury / [✓ Fatality] / Nest

Condition (circle one): [✓ Intact Carcass] / Dismembered Carcass / Feathers Only

Age of Remains (circle one): [✓ 1-5 (fluid filled eyes)] / 6-30 (maggots) / 30+ (bones)

Photo No.

Carcass Condition Details, Behavior of Injured Animal or Nest Details: Carcass was against evap pond netting. The bird was not entangled nor signs of blunt trauma. Last incidental evap pond monitoring afternoon, 6/27/13.

LOCATION

DATUM: UTM Z11 NAD83 (m) UTM N: 3727428 UTM E: 685612

Found Near (circle one):

Solar Trough / [✓ Evaporation Pond] / Road / Power Line / Other (explain below)

Location Details: West side of north evap pond. Water in pond. Packed dirt around enclosure. Carcass against netting. Pond contains water.

IDENTIFICATION

[✓ Bird] / Bat / Unknown / Other (circle one)

Species (if unknown, write 'unknown'): Great Blue Heron

Color/Markings: Grey color large bird.

Sex (circle one): -Male / Female / Unknown Age (circle one): [✓ Adult] / Juvenile / Unknown

Is Animal Tagged? (circle one): Yes / [✓ No]

Identification Remarks: N/A

ENVIRONMENTAL CONDITION

Weather (circle one): Clear / Fog / Cloudy / Rain

Approx. Temperature (circle one): [✓ °F] / °C: 84

Wind (circle one): [✓ Calm] / Gusty / Storm / Violent Storm

Habitat (circle all that apply):

Bare Ground / Creosote Bush Scrub / Sand Dunes

Sand Drifts over Playa / Ephemeral Wash / Desert Pavement

NOTIFICATION

Who was notified, and When? DB notified of find by reporting party. CM notified at 1000. on 6/28/2013 9:30:00 AM

Actions Taken (e.g., left in place, taken to rehab): Bird removed and disposed via burial.

COMMENTS:

Weather: overcast Feels humid. Ponds checked 6/27 afternoon without findings. Burial at 0688055 / 3726307

* Turn in completed form and incident photos to the on-site Environmental Manager.

* Report any incidental observations of dead birds or other wildlife at the evaporation ponds to the Designated Biologist within one day of the detection of the carcass.

* Report any nests immediately to the on-site Environmental Manager.

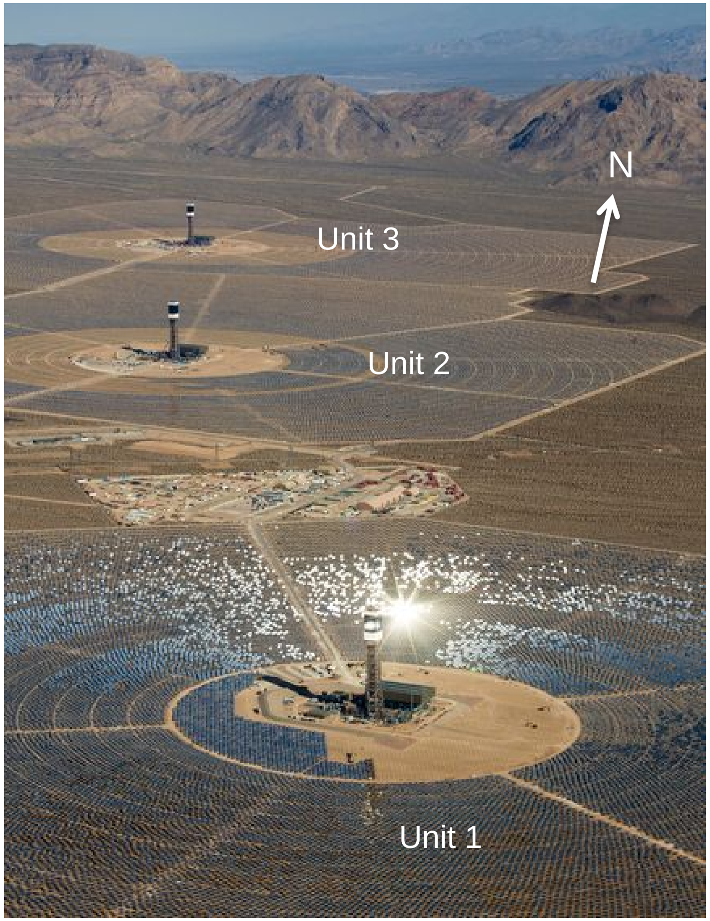
U.S. DEPARTMENT OF ENERGY

NNSA
National Nuclear Security Administration

Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Ivanpah Solar Electric Generating System

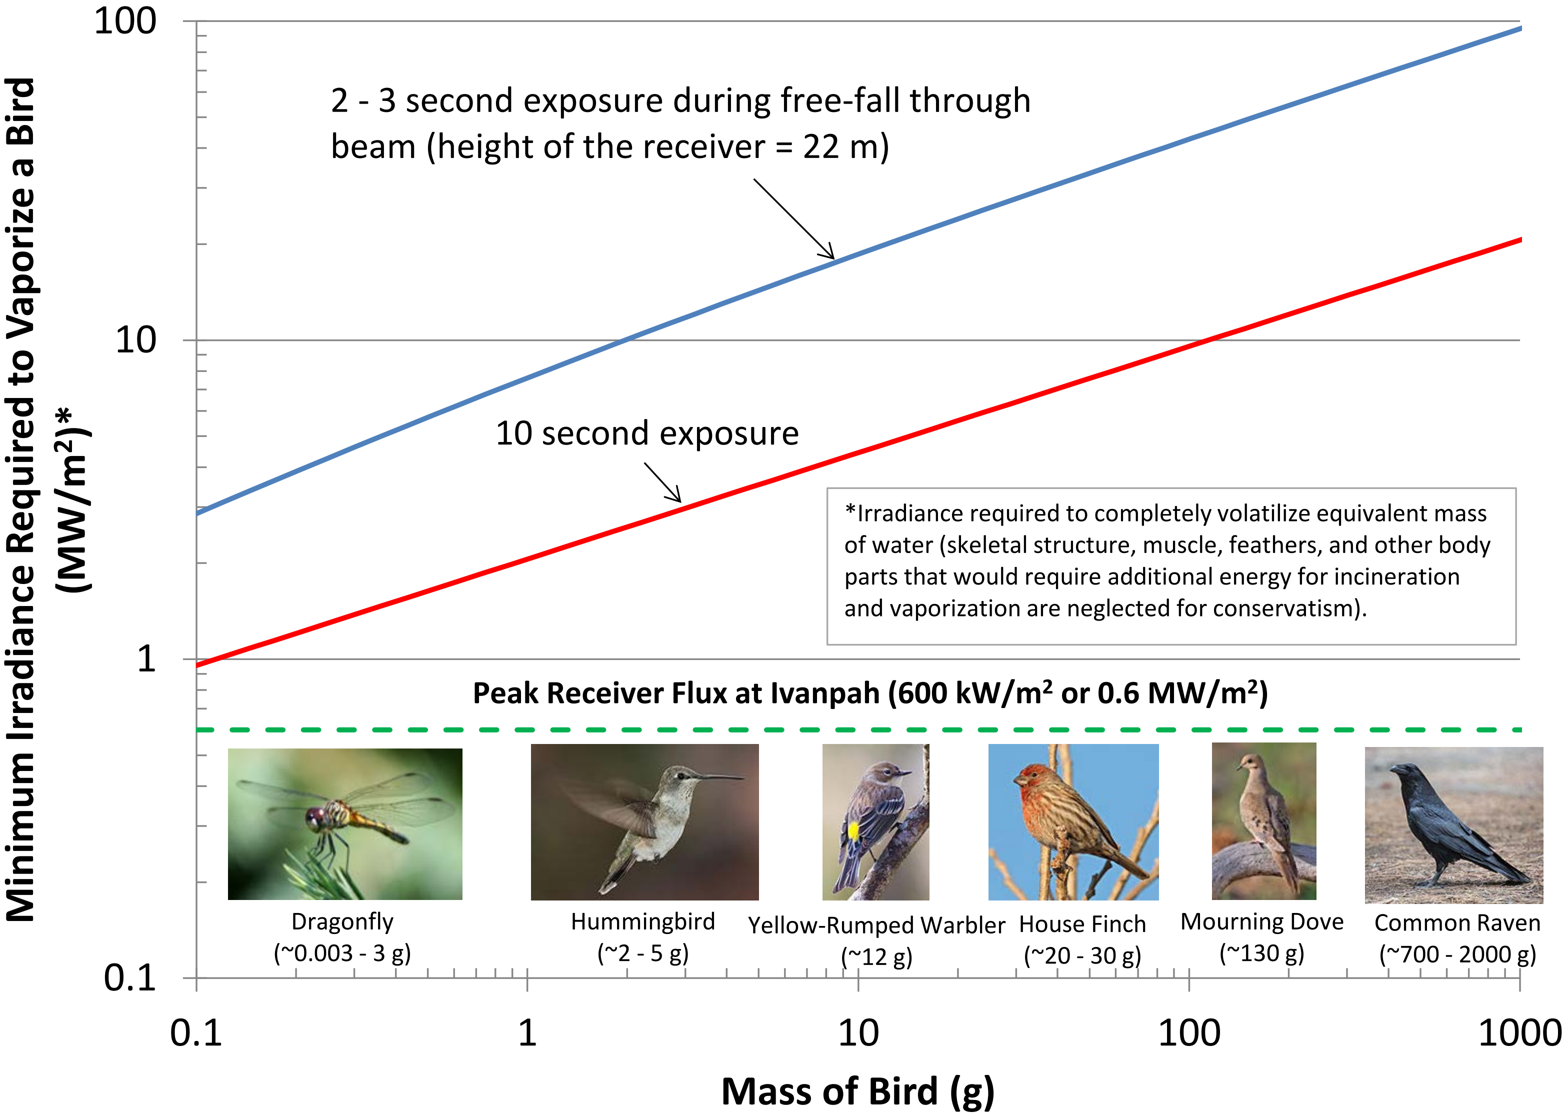
- Three power tower units (377 MW (net) / 392 MW (gross))
  - Unit 1: 126 MW
  - Unit 2: 133 MW
  - Unit 3: 133 MW
  - Each tower 140 m (459 ft) tall
- 173,500 heliostats
  - 2 mirrors/heliostat: 15.2 m^2
- Direct steam receiver (22 m tall x 17 m wide + ~16 m of white shielding)
- Dry-cooling
- 14.2 km^2 (3500 acres) on public desert land in southern California
- Owners: NRG Energy, Google, and Brightsource Energy



Vaporization Calculation

- Assume bird is composed entirely of water
- Determine energy required to volatilize equivalent mass of water (sensible heat plus latent heat)
    - Sensible (heating) energy to heat water from 40 C (average body temperature of bird) to 97 C (boiling point at elevation of Ivanpah)
    - Latent heat of vaporization to convert liquid water to vapor
- Convert energy (J) to irradiance (W/m^2) by dividing by exposure time (s) and cross-sectional area (m^2)
    - Two exposure times calculated
        - Free-fall through beam equivalent to height of receiver (22 m); ~2 – 3 sec
        - Fixed 10 sec exposure time
- Compare minimum irradiance required to volatilize a bird with prescribed mass to the peak available irradiance at Ivanpah

Irradiance Required to Vaporize a Bird



2 - 3 second exposure during free-fall through beam (height of the receiver = 22 m)

10 second exposure

*Irradiance required to completely volatilize equivalent mass of water (skeletal structure, muscle, feathers, and other body parts that would require additional energy for incineration and vaporization are neglected for conservatism).

Peak Receiver Flux at Ivanpah (600 kW/m² or 0.6 MW/m²)

Conclusions

- Complete vaporization of birds with concentrated solar flux less than 1 MW/m^2 is highly improbable
- For most common birds between 10 – 1000 g, the irradiance would need to be 4 – 20 MW/m^2 with an exposure time of 10 sec to volatilize equivalent mass of water
    - Peak irradiance (solar flux) at Ivanpah is only ~0.6 MW/m^2
    - Additional energy would be required to incinerate and vaporize bones, muscle, feather, and other body parts, which were neglected in this analysis

Appendices

- Free-fall and time of irradiance calculation
- Vaporization calculation
- References

Free-Fall Calculation

- Free-fall time over distance, H, is as follows:

$$t = \frac{v_\infty}{g}\cosh^{-1}\left(\exp\left(\frac{Hg}{v_\infty^2}\right)\right)$$

where $v_\infty = \text{terminal velocity} = 1.286 m^{1/6} \rho_w^{\ 1/3} \left(\frac{g}{\rho_a C_D}\right)^{1/2}$ assuming spherical body

g = gravitational accleration (9.81 m/s^2)
H = free-fall distance through beam = receiver height = 22 m
m = mass (kg)
ρ_a = density of ambient air = 1.2 kg/m^3
ρ_w = density of water = 992 kg/m^3 at 40 C
C_D = drag coefficient (~1 for passerine birds)*

⇨ Free-fall time through beam is ~2 – 3 sec, depending on mass

*Sum of three drag components: lift, profile, and parasite (Hedenstrom and Liechti, 2001)

Vaporization calculation

- Sensible (heating) energy:

$$E_{sensible} = mc_p \left(T_{boil} - T_{body}\right)$$

where

$E_{sensible}$ = sensible energy to bring water to boiling point (J)
m = mass (kg)
c_p = specific heat of water = 4200 J/kg-K (for T between 270 – 390 K)
T_{boil} = boiling point of water (= 97 C for atmospheric pressure at Ivanpah)
T_{body} = average body temperature of bird (= 40 C; Prinzinger et al., 1991)

Vaporization calculation

- Latent heating:

$$E_{latent} = mh_{fg}$$

where

E_{latent} = latent energy to volatilize liquid water (J)
m = mass (kg)
h_{fg} = latent heat of vaporization (=2.27e6 J/kg at 97 C)

Vaporization calculation

- Minimum irradiance required for vaporization

$$Q = \frac{E_{sensible} + E_{latent}}{At}$$

where

$$A = \frac{\pi^{1/3}}{4}\left(\frac{6m}{\rho_w}\right)^{2/3}$$

Q = irradiance (W/m^2)
$E_{sensible}$ = sensible energy to bring water to boiling point (J)
E_{latent} = latent energy to volatilize liquid water (J)
A = cross-sectional area of bird (m^2); assumed to be spherical in shape*
ρ_w = density of water = 992 kg/m^3 at 40 C
t = time of exposure (sec)

*Cross-sectional area of sphere is conservatively larger than estimates from Pennycuick (1989) for body frontal area, S_b: S_b=0.00813m$^{0.666}$

Avian Mortality at Solar Energy Facilities in Southern California: A Preliminary Analysis

Rebecca A. Kagan, Tabitha C. Viner, Pepper W. Trail, and Edgard O. Espinoza
National Fish and Wildlife Forensics Laboratory

Executive Summary

This report summarizes data on bird mortality at three solar energy facilities in southern California: Desert Sunlight, Genesis, and Ivanpah. These facilities use different solar technologies, but avian mortality was documented at each site. Desert Sunlight is a photovoltaic facility, Genesis employs a trough system with parabolic mirrors, and Ivanpah uses a power tower as a focal point for solar flux.

FINDINGS

Trauma was the leading cause of death documented for remains at the Desert Sunlight and Genesis sites. Trauma and solar flux injury were both major causes of mortality at the Ivanpah site. Exposure to solar flux caused singeing of feathers, which resulted in mortality in several ways. Severe singeing of flight feathers caused catastrophic loss of flying ability, leading to death by impact with the ground or other objects. Less severe singeing led to impairment of flight capability, reducing ability to forage and evade predators, leading to starvation or predation. Our examinations did not find evidence for significant tissue burns or eye damage caused by exposure to solar flux.

Cause of Death	Ivanpah	Genesis	Desert Sunlight	Total
Solar Flux	47	0	0	47
Impact trauma	24	6	19	49
Predation trauma	5	2	15	22
Trauma of undetermined cause	14	0	0	14
Electrocution	1	0	0	1
Emaciation	1	0	0	1
Undetermined (remains in poor condition)	46	17	22	85
No evident cause of death	3	6	5	14
Total	141	31	61	233

These solar facilities appear to represent “equal-opportunity” hazards for the bird species that encounter them. The remains of 71 species were identified, representing a broad range of ecological types. In body size, these ranged from hummingbirds to pelicans; in ecological type from strictly aerial feeders (swallows) to strictly aquatic feeders (grebes) to ground feeders (roadrunners) to raptors (hawks and owls). The species identified were equally divided among resident and non-resident species, and nocturnal as well as diurnal species were represented. Although not analyzed in detail, there was also significant bat and insect mortality at the Ivanpah site, including monarch butterflies. It appears that Ivanpah may act as a **"mega-trap,"** attracting insects which in turn attract insect-eating birds, which are incapacitated by solar flux injury, thus attracting predators and creating an entire food chain vulnerable to injury and death.

			Foraging Zone			**Residency Status**	
SITE	No. Remains	Identifiable Remains	Air	Terr	Water	Resident	Migrant
Ivanpah	141	127	28	85	14	63	64
Genesis	31	30	12	12	6	20	10
Desert Sun	61	56	7	22	27	18	38
TOTALS	233	213	47	119	47	101	112

CONCLUSIONS AND RECOMMENDATIONS

In summary, three main causes of avian mortality were identified at these facilities: impact trauma, solar flux, and predation. Birds at all three types of solar plants were susceptible to impact trauma and predators. Predation was documented mostly at the photovoltaic site, and in many cases appeared to be associated with stranding or nonfatal impact trauma with the panels, leaving birds vulnerable to resident predators. Solar flux injury, resulting from exposures to up to 800º F, was unique to the power tower facility. Our findings demonstrate that a broad ecological variety of birds are vulnerable to morbidity and mortality at solar facilities, though some differential mortality trends were evident, such as waterbirds at Desert Sunlight, where open water sources were present; and insectivores at Ivanpah, where insects are attracted to the solar tower.

Specific hazards were identified, including vertically-oriented mirrors or other smooth reflective panels; water-like reflective or polarizing panels; actively fluxing towers; open bodies of water; aggregations of insects that attracted insectivorous birds; and resident predators. Making towers, ponds and panels less attractive or accessible to birds may mitigate deaths. Specific actions should include:

Monitoring/detection measures:

1) Install video cameras sufficient to provide 360 degree coverage around each tower to record birds (and bats) entering and exiting the flux

2) For at least two years (and in addition to planned monitoring protocol), conduct daily surveys for birds (at all three facilities), as well as insects and bats (in the condenser building at Ivanpah) around each tower at the base of and immediately adjacent to the towers in the area cleared of vegetation. Timing of daily surveys can be adjusted to minimize scavenger removal of carcasses as recommended by the TAC. Surveys in the late afternoon might be optimal for bird carcasses, and first light for bat carcasses.

3) Use dogs for monitoring surveys to detect dead and injured birds that have hidden themselves in the brush, both inside and outside the perimeter of the facility

4) To decrease removal of carcasses, implement appropriate raven deterrent actions

Bird Mortality Avoidance Measures*:*

1) Increase cleared area around tower at Ivanpah to decrease attractive habitat; at least out to fence

2) Retrofit visual cues to existing panels at all three facilities and incorporate into new panel design. These cues should include UV-reflective or solid, contrasting bands spaced no further than 28 cm from each other

3) Suspend power tower operation during peak migration times for indicated species

4) Avoid vertical orientation of mirrors whenever possible, for example tilt mirrors during washing

5) Properly net or otherwise cover ponds

6) Place perch deterrent devices where indicated, eg. on tower railings near the flux field

7) Employ exclusionary measures to prevent bats from roosting in and around the condenser facility at Ivanpah.

It must be emphasized that we currently have a very incomplete knowledge of the scope of avian mortality at these solar facilities. Challenges to data collection include: large facilities which are difficult to efficiently search for carcasses; vegetation and panels obscuring ground visibility; carcass loss due to scavenging; rapid degradation of carcass quality hindering cause of death and species determination; and inconsistent documentation of carcass history.

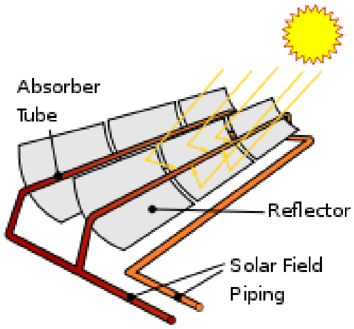
To rectify this problem, video cameras should be added to the solar towers to record bird mortality and daily surveys of the area at the base of and immediately adjacent to the towers should be conducted. At all the facilities, a protocol for systematic, statistically-rigorous searches for avian remains should be developed, emphasizing those areas where avian mortality is most likely to occur. Investigation into bat and insect mortalities at the power tower site should also be pursued.

Finally, there are presently little data available on how solar flux affects birds and insects. Studies of the temperatures experienced by objects in the flux; of the effects of high temperatures on feather structure and function; and of the behavior of insects and birds in response to the flux and related phenomena (e.g. "light clouds") are all essential if we are to understand the scope of solar facility effects on wildlife.

Introduction

The National Fish and Wildlife Forensics Laboratory was requested to determine cause of death for birds found at facilities that generate electricity from solar energy. Solar generating facilities can be classified into three major types: photovoltaic sites, trough systems and solar power towers. There is much written about these systems so this report will not include any technical details, but simply mention the differences and their potential impact on birds.

1) **Photovoltaic systems** directly convert the sun's light into electricity. The perceived threat to birds is associated with the presence of water ponds which attract birds and from traumatic impact with the photovoltaic cells. An example of this type of solar power plant is Desert Sunlight Solar Farm (AKA First Solar).



2) **Trough systems** are composed of parabolic mirrors which focus and reflect the sun to a tube that converts the heat from the sun into electricity. The perceived threat to birds is associated with the presence of water ponds which attract birds and from traumatic impact with the trough structures. An example of this type of solar power plant is Genesis Solar Energy Project.

3) **Solar power towers** use thousands of mirrors to reflect the solar energy to a tower, where water in a boiler is converted to steam, generating the electricity. The perceived threat to birds is associated traumatic impact with the mirrors and the danger associated with the heat produced by the mirrors. An example of this type of solar power plant is Ivanpah Solar Electric Generating System.

Methods

Carcasses were collected at the different solar power plant sites by either US Fish and Wildlife Service employees or by energy company staff. The collection of the carcasses was opportunistic; that is, not according to a pre-determined sampling schedule or protocol. There was no attempt to quantify the number of carcasses that scavengers or predators removed from the solar facilities' grounds, or to compare the distribution of carcasses inside and outside the boundaries of the solar facility sites.

Additionally, three USFWS/-OLE staff, including two Forensics Lab staff (EOE and RAK), visited the Ivanpah Solar plant from October 21 – 24, 2013. Their on-site observations are included in this report.

A total of 233 birds collected from three different facilities were examined; 141 from a solar thermal power tower site (Ivanpah, Bright Source Inc.), 31 from a parabolic trough site (Genesis, NextEra Energy Inc.) and 61 from a photovoltaic (PV) panel site (Desert Sunlight, First Solar Inc.). Nine of the Ivanpah birds were received fresh; 7 of those were necropsied during a site visit by a Forensics Laboratory pathologist (RAK). The rest of the birds were received frozen and allowed to thaw at room temperature prior to species identification and necropsy. Species determination was made by the Forensics Laboratory ornithologist (PWT) for all birds either prior to necropsy or, for those necropsied on-site, from photos and the formalin-fixed head. All data on carcass history (location of the carcass, date of collection and any additional observations) were transcribed, although these were not available for all carcasses.

As part of the gross pathological examination, whole carcasses were radiographed to help evaluate limb fractures and identify any metal foreign bodies. Alternate light source examination using an Omnichrome Spectrum 9000+ at 570 nm with a red filter helped rule in or out feather burns by highlighting subtle areas of feather charring (Viner et al., 2014). All birds or bird parts from Ivanpah without obvious burns were examined with the alternate light source, as well as any bird reportedly found near a power line and a random sub-sample of the remaining birds from Genesis and Desert Sunlight (Viner, T. C., R. A. Kagan, and J. L. Johnson, 2014, Using an alternate light source to detect electrically singed feathers and hair in a forensic setting. Forensic Science International, v. 234, p. e25-e29).

Carcass quality varied markedly. If carcasses were in good post mortem condition, representative sections of heart, lung, kidney, liver, brain and gastrointestinal tract as well as any tissues with gross lesions were collected and fixed in 10% buffered formalin. Full tissue sets were collected from the fresh specimens. Formalin-fixed tissues were routinely processed for histopathology, paraffin-embedded, cut at 4 µm and stained with hematoxylin and eosin. Tissues from 63 birds were examined microscopically: 41 from Ivanpah, 1 from Genesis and 21 from Desert Sunlight.

Birds with feather burns were graded based on the extent of the lesions. Grade 1 birds had curling of less than 50% of the flight feathers. Grade 2 birds had curling of 50% or more of the flight feathers. Grade 3 birds had curling and visible charring of contour feathers (Figure 1).

Figure 1: Three grades of flux injury based on extent and severity of burning. Grade 1 (top); Yellow-rumped Warbler with less than 50% of the flight feathers affected (note sparing of the yellow rump feathers). Grade 2 (middle); Northern Rough-winged Swallow initially found alive but unable to fly, with greater than 50% of the flight feathers affected. Grade 3 (bottom); MacGillivray's Warbler with charring of feathers around the head, neck, wings and tail.

Bird Species Recovered at Solar Power Facilities

Tables 1-4 and Appendix 1 summarize 211 identifiable bird remains recovered from the three solar facilities included in this study. These birds constitute a taxonomically diverse assemblage of 71 species, representing a broad range of ecological types. In body size, these species ranged from hummingbirds to pelicans; in ecological type from strictly aerial feeders (e.g. swifts and swallows) to strictly aquatic feeders (pelicans and cormorants) to ground feeders (roadrunners) to raptors (hawks and owls). The species identified were equally divided among resident and non-resident species. Nocturnal as well as diurnal species were represented.

In Tables 1-4 and Appendix 1, bird species are categorized into very general ecological types by foraging zone and residency status. Foraging Zones were "air" (a significant portion of foraging activity performed in the air), "terrestrial" (including foraging both in vegetation and on the ground), and "water" (foraging associated with water, including waders as well as aquatic birds). Residency Status was "resident" (for breeding or year-round residents) and "migrant" (for both passage migrants and non-breeding-season residents). For a number of species, the appropriate classification for residency status was uncertain, due to a lack of detailed knowledge of the sites. The present classification is based on published range maps, and is subject to revision as more information becomes available.

This dataset is not suitable for statistical analysis, due to the opportunistic and unstandardized collection of avian remains at the facilities, and the lack of baseline data on bird diversity and abundance at each site. Nevertheless, a few conclusions can be noted. First, these data do not support the idea that these solar facilities are attracting particular species. Of the 71 bird species identified in remains, only five species were recovered from all three sites. These five were American Coot, Mourning Dove, Lesser Nighthawk, Tree Swallow, and Brown-headed Cowbird, again emphasizing the ecological variety of birds vulnerable to mortality at the solar facilities. Over two-thirds (67%) of the species were found at only a single site

(Appendix 1). That being said, the Desert Sunlight facility had particularly high mortality among waterbirds, suggesting a need to render the ponds at that site inaccessible or unattractive to these species.

The diversity of birds dying at these solar facilities, and the differences among sites, suggest that there is no simple "fix" to reduce avian mortality. These sites appear to represent "equal-opportunity" mortality hazards for the bird species that encounter them. Actions to reduce or mitigate avian mortality at solar facilities will need to be designed on a site-specific basis, and will require much more data on the bird communities at each site, and on how mortality is occurring. Carefully-designed mortality studies might reveal significant patterns of vulnerability that are not evident in these data.

Table 1. Summary data on avian mortality at the three solar sites included in this study. See summary for discussion of Foraging Zone and Residency Status categories.

				Foraging Zone			**Residency Status**	
SITE	**No. Species**	**No. Remains**	**Identifiable Remains**	**Air**	**Terr**	**Water**	**Resident**	**Migrant**
Ivanpah	49	141	127	26	85	14	63	64
Genesis	15	31	30	12	12	6	20	10
Desert Sun	33	61	56	7	22	27	18	38
TOTALS	71	233	213	47	119	47	101	112

Table 2. Species identified from avian remains at the Desert Sunlight photovoltaic solar facility. MNI = minimum number of individuals of each species represented by the identifiable remains. In some cases (e.g. Cinnamon/Blue-winged Teal), closely related species could not be distinguished based on the available remains, but the Foraging Zone and Residency Status could still be coded, due to the ecological similarities of the species involved. Total identified birds = 56.

Cause of Death of Birds Found at the Solar Power Plants

Photovoltaic facility (Desert Sunlight):

Sixty-one birds from 33 separate species were represented from Desert Sunlight. Due to desiccation and scavenging, a definitive cause of death could not be established for 22 of the 61 birds (see Table 5). Feathers could be examined in all cases, however, and none of the 61 bird remains submitted from the PV facility had visible evidence of feather singeing, a clear contrast with birds found at Ivanpah.

Blunt force impact trauma was determined to have been the cause of death for 19 Desert Sunlight birds including two Western Grebes (*Aechmophorus occidentalis*) and one each of 16 other species. Impact (blunt force) trauma is diagnosed by the presence of fractures and internal and/or external contusions. In particular, bruising around the legs, wings and chest are consistent with crash-landings while fractures of the head and/or neck are consistent with high-velocity, frontal impact (such as may result from impacting a mirror).

Predation was the immediate cause of death for 15 birds. Lesions supporting the finding of predation included decapitation or missing parts of the body with associated hemorrhage (9/15), and lacerations of the skin and pectoral muscles. Eight of the predated birds from Desert Sunlight were

Figure 2: Predation trauma (top) resulting in traumatic amputation of the head and neck (American Avocet) and impact trauma (bottom) causing bruising of the keel ridge of the sternum (Brown Pelican).

grebes, which are unable to easily take off from land. This suggests a link between predation and stranding and/or impact resulting from confusion of the solar panels with water (see Discussion).

Parabolic trough facility (Genesis):

Thirty-one birds were collected from this site. There were 15 species represented. Those found in the greatest numbers were Brown-headed Cowbirds and Cliff Swallows, though no more than 6 individuals from any given species were recovered. Overall, carcass quality was poor and precluded definitive cause of death determination in 17/31 birds (Table 5). Identifiable causes of death consisted of impact trauma (6/31) and predation trauma (2/31). Necropsy findings were similar to those at Desert Sunlight with fractures and hemorrhage noted grossly. Predation trauma was diagnosed in two birds, a Cliff Swallow and a Ring-billed Gull.

Power tower facility (Ivanpah):

Ivanpah is the only facility in this study that produces solar flux, which is intense radiant energy focused by the mirror array on the power-generating tower. Objects that pass through this flux, including insects and birds, encounter extreme heat, although the extent of heating depends on many variables, including the duration of exposure and the precise location in the flux beam.

From Ivanpah, 141 birds were collected and examined. Collection dates spanned a period of one year and five months (July 2012 to December 2013) and included at least seven months of construction during which time the towers were not actively fluxing (2013). There were 49 species represented (Table 4). Those found in the greatest numbers were Yellow-rumped Warblers (*Setophaga coronata;* 14), House Finches (*Carpodacus mexicanus*; 13), Mourning Doves (*Zenaida macroura*; 11) and American Coots (*Fulica americana*; 7). Yellow-rumped Warblers and House Finches were found exclusively at the power tower site.

Solar flux injury was identified as the cause of death in 47/141 birds. Solar flux burns manifested as feather curling, charring, melting and/or breakage and loss. Flight feathers of the tail and/or wings were invariably affected. Burns also tended to occur in one or more of the following areas; the sides of the body (axillae to pelvis), the dorsal coverts, the tops and/sides of the head and neck and the dorsal body wall (the back). Overlapping portions of feathers and light-colored feathers were often spared (Figures 3 and 4).

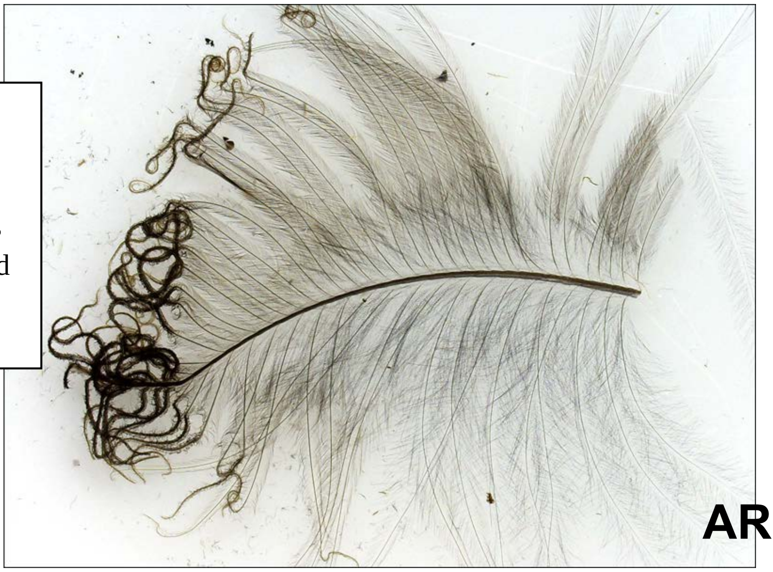

Figure 3: contour feather from the back of a House Finch with Grade 3 solar flux injury. The feather has curling and charring limited to the exposed tip.

Figure 4: Feather from a Peregrine Falcon with Grade 2 solar flux injury. Note burning of dark feather bands with relative sparing of light bands.

The yellow and red rumps of Yellow-rumped Warblers and House Finches respectively remained strikingly unaffected (See Figure 1). Charring of head feathers, in contrast, was generally diffuse across all color patterns. A pattern of spiraling bands of curled feathers across or around the body and wings was often apparent.

Table 5. Cause of death (COD) data

Cause of Death	Ivanpah	Genesis	Desert Sunlight	Total
Solar Flux	47	0	0	47
Impact trauma	24	6	19	49
Predation trauma	5	2	15	22
Trauma of undetermined cause	14	0	0	14
Electrocution	1	0	0	1
Emaciation	1	0	0	1
Undetermined (remains in poor condition)	46	17	22	85
No evident cause of death	3	6	5	14
Total	141	31	61	233

Eight birds were assigned a feather damage Grade of 1 with curling of less than 50% of the flight feathers. Six of these had other evidence of acute trauma (75%). Five birds were Grade 2, including three birds that were found alive and died shortly afterwards. Of these birds, 2 (the birds found dead) also had evidence of acute trauma. Twenty-eight birds were Grade 3; with charring of body feathers. Of these birds, 21/28

(28%) had other evidence of acute trauma. Remaining carcasses (6) were incomplete and a grade could not be assigned.

Twenty-nine birds with solar flux burns also had evidence of impact trauma. Trauma consisted of skull fractures or indentations (8), sternum fractures (4), one or more rib fractures (4), vertebral fractures (1), leg fracture (3), wing fracture (1) and/or mandible fracture (1). Other signs of trauma included acute macroscopic and/or microscopic internal hemorrhage. Location found was reported for 39 of these birds; most of the intact carcasses were found near or in a tower. One was found in the inner heliostat ring and one was found (alive) on a road between tower sites. The date of carcass collection was provided for 42/47. None were found prior to the reported first flux (2013).

Figure 5: The dorsal aspect of the wing from a Peregrine Falcon (the same bird as shown in Figure 4) with Grade 2 lesions. Note extensive curling of feathers without visible charring. This bird was found alive, unable to fly, emaciated and died shortly thereafter. These findings demonstrate fatal loss of function due to solar flux exposure in the absence of skin or other soft tissue burns.

Among the solar flux cases, a variety of bird species were affected though all but one (a raptor) was a passerine (Appendix 2). House Finches and yellow-rumped Warblers were most often represented (10/47 and 12/47 respectively). For the birds in which species could be determined (41/47), insects were a major dietary component in all but two species. These were an unidentified hummingbird (*Selasphorus*) species (known to include insects in the diet) and a Peregrine Falcon (a species that feeds on small birds).

Four birds were reportedly found alive and taken to a wildlife rehabilitation center where they died one to a few days later (exact dates were not consistently provided). Three had Grade 2 feather burns and one had Grade 3 feather burns. None had other evidence of trauma. Body condition was reduced in all of the birds (two considered thin and two emaciated) based on a paucity of fat stores and depletion of skeletal muscling. The four birds were of four different species and consisted of three passerines and one raptor.

The second most commonly diagnosed cause of death at the Ivanpah facility was impact (or blunt force) trauma (24/141 birds). Necropsy findings were as previously described at the Desert Sunlight facility. Impact marks were reported on heliostat mirrors adjacent to the carcasses in 5 cases and mirrors were described as being vertically-oriented in 5 cases. Specific carcass locations were reported for 18 of the birds. Those birds were found in a variety of areas; below heliostats (8/18), in or near tower and powerblock buildings (4/18), on roads (2/18), below power lines (2/18), in the open (1/18) and by a desert tortoise pen (1/18).

Predation was determined to be the cause of death for five of the birds. A coot and a Mourning Dove were found with extensive trauma and hemorrhage to the head and upper body consisting of lacerations, crush trauma and/or decapitation. One of the birds (an American Coot) was found near a kit fox shelter site. One bird (Northern Mockingbird) was found near the fence line and the third (a Mourning Dove) in an alley way. Two more birds (an unidentified sparrow and an American Pipit) were observed being eaten by one of the resident Common Ravens.

Discussion of Cause of Death of Birds Found at the Solar Power Plants

Impact trauma:

Sheet glass used in commercial and residential buildings has been well-established as a hazard for birds, especially passerines (Klem 1990, 2004, 2006; Loss et al. 2014). A recent comprehensive review estimated that between 365-988 million birds die annually by impacting glass panels in the United States alone (median estimate 599 million; Loss et al. 2014). Conditions that precipitate window strike events include the positioning of vegetation on either side of the glass and the reflective properties of the window. Glass panels that reflect trees and other attractive habitat are involved in a higher number of bird collisions.

The mirrors and photovoltaic panels used at all three facilities are movable and generally directed upwardly, reflecting the sky. At the Ivanpah facility, when heliostats are oriented vertically (typically for washing or installation, personal communication, RAK) they appear to pose a greater risk for birds. Of the eight birds reported found under a heliostat, heliostats were vertically-oriented in at least 5 cases. (D Klem Jr., DC Keck, KL Marty, AJ Miller Ball, EE Niciu, and CT Platt. 2004. Effects of window angling, feeder placement, and scavengers on avian mortality at plate glass. Wilson Bulletin, 116(1):69-73; D Klem Jr. 2006. Glass: A deadly conservation issue for birds. Bird Observer 34(2):73-81; D Klem Jr. 1990.

Collisions between birds and windows: mortality and prevention. Journal of Field Ornithology 61:120–128; Loss, S.R., T. Will, S.S.Loss, and P.P. Marra. 2014. Bird-building collisions in the United States: Estimates of annual mortality and species vulnerability. Condor 116: 8-23). Studies with aquatic insects have found that vertically-oriented black glass surfaces (similar to solar panels) produced highly polarized reflected light, making them highly attractive (Kriska, G., P. Makik, I. Szivak, and G. Horvath. 2008. Glass buildings on river banks as “polarized light traps” for mass-swarming polarotactic caddis flies. Naturwissenschaften 95: 461-467).

A desert environment punctuated by a large expanse of reflective, blue panels may be reminiscent of a large body of water. Birds for which the primary habitat is water, including coots, grebes, and cormorants, were over-represented in mortalities at the Desert Sunlight facility (44%) compared to Genesis (19%) and Ivanpah (10%). Several factors may inform these observations. First, the size and continuity of the panels differs between facilities. Mirrors at Ivanpah are individual, 4 x 8’ panels that appear from above as stippling in a desert background (Figure 6). Photovoltaic panels at Desert Sunlight are long banks of adjacent 27.72 x 47.25” panels (70 x 120 cm), providing a more continuous, sky/water appearance. Similarly, troughs at Genesis are banks of 5 x 5.5’ panels that are up to 49-65 meters long.

Figure 6: The Ivanpah Solar Electric Generating System as seen via satellite. The mirrored panels are 5 x 8 feet.

There is growing concern about "polarized light pollution" as a source of mortality for wildlife, with evidence that photovoltaic panels may be particularly effective sources of polarized light in the environment (see Horvath et al. 2010. Reducing the maladaptive attractiveness of solar panels to polarotactic insects. Conservation Biology 24: 1644-1653, and ParkScience, Vol. 27, Number 1, 2010; available online at: http://www.nature.nps.gov/parkscience/index.cfm?ArticleID=386&ArticleTypeID=5; as well as discussion of this issue in the Desert Sunlight Final Environmental Impact Statement, Chapter 4, pp. 14-15).

Variables that may affect the illusory characteristics of solar panels are structural elements or markings that may break up the reflection. Visual markers spaced at a distance of 28 cm or less have been shown to reduce the number of window strike events on large commercial buildings (City of Toronto Green Development Standard; Bird-friendly development guidelines. March 2007). Mirrors at the Ivanpah facility are unobscured by structures or markings and present a diffuse, reflective surface. Photovoltaic panels at Desert Sunlight are arranged as large banks of small units that are 60 x 90 cm. The visually uninterrupted expanse of both these types of heliostat is larger than that which provides a solid structure visual cue to passerines. Parabolic troughs at Genesis have large, diffusely reflective surfaces between seams that periodically transect the bank of panels at 5.5' intervals. Structures within the near field, including the linear concentrator and support arms, and their reflection in the panels and may provide a visual cue to differentiate the panel as a solid structure.

The paper by Horvath et al cited above provides experimental evidence that placing a white outline and/or white grid lines on solar panels significantly reduced the attractiveness of these panels to aquatic insects, with a loss of only 1.8% in energy-producing surface area (p. 1651). While similar detailed studies have yet to be carried out with birds, this work, combined with the window strike results, suggest that significant reductions in avian mortality at solar facilities could be achieved by relatively minor modifications of panel and mirror design. This should be a priority for further research.

Finally, ponds are present on the property of the Desert Sunlight and Genesis facilities. The pond at Genesis is netted, reducing access by migratory birds, while the pond at Desert Sunlight is open to flighted wildlife. Thus, birds are both attracted to the water feature at Desert Sunlight and habituated to the presence of an accessible aquatic environment in the area. This may translate into the misinterpretation of a diffusely reflected sky or horizonal polarized light source as a body of water.

Stranding and Predation:

Predation is likely linked to panel-related impact trauma and stranding. Water birds were heavily over-represented in predation mortalities at Desert Sunlight. Of the 15 birds that died due to predation, 14 make their primary habitat on water (coots, grebes, a cormorant, and an avocet). A single White-winged Dove was the only terrestrial-based predation mortality in the submitted specimens. This is in contrast to blunt trauma mortalities at Desert Sunlight in which 8 of the 19 birds determined to have died of impact trauma were water species.

Locations of the birds when found dead were noted on several submissions. Of the birds that died of predation for which locations were known, none were located near ponds. The physiology of several of these water birds is such that locomotion on land is difficult or impossible. Grebes in particular have very limited mobility on land and require a run across water in order to take off (Jehl, J. R., 1996. Mass mortality events of Eared Grebes in North America. Journal of Field Ornithology 67: 471-476). Thus, these birds likely did not reach their final location intentionally. Ponds at the PV and trough sites are fenced, prohibiting terrestrial access by predators. Birds on the water or banks of the pond are inaccessible to resident predators. Therefore, it is unlikely that the birds were captured at the pond and transported by a predator into the area of the panels. Attempts to land or feed on the panels because of their deceptive appearance may have injured the birds to the point that they could not escape to safety, or inadvertently stranded the birds on a substrate from which they could not take flight. We believe that an inability to quickly flee after striking the panels and stranding on the ground left these birds vulnerable to opportunistic predators. At least two types of predators, kit foxes and ravens, have been observed in residence at the power tower and PV facilities and ravens have been reported at the trough site (personal communication and observation, RAK). Additionally, histories for multiple birds found at the tower site document carcasses found near kit fox shelters or being eaten or carried by a raven.

Solar Flux:

Avian mortality due to exposure to solar flux has been previously explored and documented (McCrary, M. D., McKernan, R. L., Schreiber, R. W., Wagner, W. D., and Sciarrotta, T. C. Avian mortality at a solar energy power plant. Journal of Field Ornithology, 57(2): 135-141). Solar flux injury to the birds of this report, as expected, occurred only at the power tower facility. Flux injury grossly differed from other sources of heat injury, such as electrocution or fire. Electrocution injury requires the bridging of two contact points and is, therefore, seen almost exclusively in larger birds such as raptors. Contact points tend to be on the feet, carpi and/or head and burns are often found in these areas. Electrocution causes deep tissue damage as opposed to the surface damage of fire or solar flux. Other sequelae include amputation of limbs with burn marks on bone, blood vessel tears and pericardial hemorrhage. Burns from fires cause widespread charring and melting of feathers and soft tissues and histopathologic findings of soot inhalation or heat damage to the respiratory mucosa. None of these were characteristics of flux injury. In the flux cases small birds were over-represented, had burns generally limited to the feathers and internal injuries attributable to impact. Flux injury inconsistently resulted in charring, tended to affect feathers along the dorsal aspects of the wings and tail, and formed band-like patterns across the body (Divincenti, F. C., J. A. Moncrief, and B. A. Pruitt. 1969. Electrical injuries: a review of 65 cases. The Journal of Trauma 9: 497-507).

Proposed mechanisms of solar flux-related death follow one or a combination of the following pathways:

- impact trauma following direct heat damage to feathers and subsequent loss of flight ability
- starvation and/or thermoregulatory dysfunction following direct heat damage to feathers
- shock
- soft tissue damage following whole-body exposure to high heat
- ocular damage following exposure to bright light.

Necropsy findings from this study are most supportive of the first three mechanisms.

Loss of feather integrity has effects on a bird's ability to take off, land, sustain flight and maneuver. Tail feathers are needed for lift production and maneuverability, remiges are needed for thrust and lift and feathers along the propatagium and coverts confer smoothness to the avian airfoil. Shortening of primary flight feathers by as little as 1.6 cm with loss of secondary and tertiary remiges has been shown to eliminate take-off ability in house sparrows further demonstrating the importance of these feathers (Brown, R. E., and A. C. Cogley, 1996. Contributions of the propatagium to avian flight: Journal of Experimental Zoology 276: 112-124). Loss of relatively few flight feathers can, therefore, render a bird unable or poorly-able to fly. Birds encountering the flux field at Ivanpah may fall as far as 400 feet after feather singeing. Signs of impact trauma were often observed in birds with feather burns and are supportive of sudden loss of function (Beaufrere, H., 2009. A review of biomechanic and aerodynamic considerations of the avian thoracic limb. Journal of Avian Medicine and Surgery 23: 173-185).

Birds appear to be able to survive flux burns in the short term, as evidenced by the collection of several live birds with singed feathers. Additionally, Forensic Lab staff observed a falcon or falcon-like bird with a plume of smoke arising from the tail as it passed through the flux field. Immediately after encountering the flux, the bird exhibited a controlled loss of stability and altitude but was able to cross the perimeter fence before landing. The bird could not be further located following a brief search (personal observation, RAK and EOE). Birds that initially survive the flux exposure and are able to glide to the ground or a perch may be disabled to the point that they cannot efficiently acquire food, escape predators or thermoregulate. Observations of emaciation in association with feather burns in birds found alive is supportive of debilitation subsequent to flux exposure. More observational studies and follow-up are required to understand how many birds survive flux exposure and whether survival is always merely short-term. As demonstrated by the falcon, injured birds (particulary larger birds), may be ambulatory enough to glide or walk over the property line indicating a need to include adjacent land in carcass searches.

There was evidence of acute skin burns on the heads of some of the Grade 3 birds that were found dead. But interestingly, tissue burn effects could not be demonstrated in birds known to have survived short periods after being burned. Hyperthermia causing instantaneous death manifests as rapid burning of tissue, but when death occurs a day or later there will be signs of tissue loss, inflammation, proteinic exudate and/or cellular death leading to multisystemic organ failure. The beginnings of an inflammatory response to injury can be microscopically observed within one to a few hours after the insult and would have been expected in any of the four birds found alive. Signs of heat stroke or inhalation of hot air should have been observable a day or more after the incident. Rather, in these cases extensive feather burns on the body largely appeared to be limited to the tips of the feathers with the overlapping portions insulating the body as designed. This, in conjunction with what is likely only a few seconds or less spent in the flux, suggests that skin or internal organ damage from exposure to high temperatures in solar flux may not be a major cause of the observed mortality.

Ocular damage following light exposure was also considered but could not be demonstrated in the submitted birds. In the four birds that initially survived, there were no signs of retinal damage, inflammation or other ocular trauma. Given the small sample size, this does not preclude sight impairment as a possible sequela but clinical monitoring of survivors would be needed to draw more definitive conclusions.

Other/Undetermined:

Powerline electrocution was the cause of death for one bird (a juvenile Common Raven) at the Ivanpah facility. Electrocution at these solar facilities is a potential hazard but, thus far, appears to be an uncommon cause of death.

Smashed birds (13/233) were found at all three locations. Detailed carcass collection information was provided for 6; all were found on roads. Though poor carcass quality in all cases precluded definitive cause death determination, circumstances and carcass condition suggest vehicle trauma as the cause of deaths. The relatively low numbers of vehicle collisions may be attributed to slow on-site vehicle speeds and light traffic. Vehicle collisions, therefore, do not appear to be a major source of mortality and would be expected to decrease as construction ends.

There was a large number of birds (85/233) for which a cause of death could not be determined due to poor carcass condition. The arid, hot environment at these facilities leads to rapid carcass degradation which greatly hinders pathology examination. Results were especially poor for birds from the Genesis facility, where the cause of death(s) for 23/31 (74%) could not be determined. These results underscore the need for carcasses to be collected soon after death. More frequent, concerted carcass sweeps are advised.

Insect mortality and solar facilities as “mega-traps”

An ecological trap is a situation that results in an animal selecting a habitat that reduces its fitness relative to other available habitats (Robertson, B.A. and R.L. Hutto. 2006. A framework for understanding ecological traps and an evaluation of existing evidence. Ecology 87: 1075-1085; Robertson, B.A., J.S. Rehage, and Sih, A. 2013. Ecological novelty and the emergence of evolutionary traps. Trends in Ecology and Evolution 28: 552-560).

A wide variety of circumstances may create ecological traps, ranging from subtle (songbirds attracted to food resources in city parks, where they are vulnerable to unnaturally high populations of predators) to direct (birds are attracted to oil-filled ponds, believing it to be water, and become trapped). It appears that solar flux facilities may act as **“mega-traps,”** which we define as artificial features that attract and kill species of multiple trophic layers. The strong light emitted by these facilities attract insects, which in turn attract insect-eating birds, which are incapacitated by solar flux injury, thus attracting predators and creating an entire food chain vulnerable to injury and death.

OLE staff observed large numbers of insect carcasses throughout the Ivanpah site during their visit. In some places there were hundreds upon hundreds of butterflies (including monarchs, *Danaus plexippus*) and dragonfly carcasses. Some showed singeing, and many appeared to have just fallen from the sky. Careful observation with binoculars showed the insects were active in the bright area around the boiler at the top of the tower. It was deduced that the solar flux creates such a bright light that it is brighter than the surrounding daylight. Insects were attracted to the light and could be seen actively flying the height of the tower. Birds were also observed feeding on the insects. At times birds flew into the solar flux and ignited. Bird carcasses recovered from the site showed the typical singed feathers. The large populations of insects may also attract indigenous bat species, which were seen roosting in structures at the base of the power tower.

Monarch butterflies in North America – both east and west of the Rocky Mountains – have been documented to be in decline (see the North American Monarch Conservation Plan, available at: http://www.mlmp.org/Resources/pdf/5431_Monarch_en.pdf). Proposed causes include general habitat loss and specific loss of milkweed, upon which the butterflies feed and reproduce. Considering the numerous monarch butterfly carcasses seen at the Ivanpah facility, it appears that solar power towers could have a significant impact on monarch populations in the desert southwest. Analysis of the insect mortality at Ivanpah, and systematic observations of bird/insect interactions around the power tower, is clearly needed.

Bird species affected by solar flux include both insectivores (e.g. swallows, swifts, flycatchers, and warblers) and raptors that prey on insect-feeding birds. Based on observations of the tower in flux and the finding of large numbers of butterflies, dragonflies and other insects at the base of the tower and in adjacent buildings it is suspected that the bright light generated by solar flux attracts insects, which in turn attracts insectivores and predators of insectivores. Waterbirds and other birds that feed on vegetation were not found to have solar flux burns. Birds were observed perching and feeding on railings at the top of the tower, apparently in response to the insect aggregations there.

Further, dead bats found at the Ivanpah site could be attracted to the large numbers of insects in the area. Nineteen bats from the condenser area of the power tower facility have been submitted to NFWFL for further evaluation. These bats belong to the Vespertilionidae and Molossidae families, which contain species considered by the Bureau of Land Management to be sensitive species in California. Preliminary evaluation revealed no apparent singing of the hair, and analysis is ongoing.

Solar flux and heat associated with solar power tower facilities

Figure 7 Ivanpah solar power facilities
http://ivanpahsolar.com/about

Despite repeated requests, we have been unsuccessful in obtaining technical data relating to the temperature associated with solar flux at the Ivanpah facility. The following summarizes the information we have gathered from other sources.

The Ivanpah solar energy generating facility consists of mirrors that reflect sunlight to a tower. In the tower sits a boiler that generates steam which then powers a turbine.

At the top of a 459 foot tall tower sits a boiler (solar receiver) that is heated by the sun rays reflected by 300,000 mirrors, called solar heliostats. When the concentrated sunlight strikes the boiler tubes, it heats the water to create superheated steam. The high temperature steam is then piped from the boiler to a turbine where electricity is generated (http://ivanpahsolar.com/about visited on 01/20/2014).

Figure 8: Seville solar power facility (http://inhabitat.com/sevilles-solar-power-tower)

If all the solar heliostats are focused on the solar tower the beams multiply the strength of sunlight by 5000 times, and this generates temperatures at the solar tower in excess of 3600° Fahrenheit (> 1982° Celsius). Since steel melts at 2750° Fahrenheit (1510° Celsius), only a percentage of heliostats are focused on the solar receiver so that) the optimal temperature at the tower is approximately 900° Fahrenheit (~482° Celsius) ("How do they do it" Wag TV for Discovery Channel, Season 3, Episode 15, "Design Airplane Parachutes, Create Solar Power, Make Sunglasses" Aired August 25, 2009).

A solar steam plant in Coalinga that also uses heliostat technology for extracting oil is on record stating that the steam generator is set to about 500° Celsius. (http://abclocal.go.com/kDSn/story?section=news%2Fbusiness&id=8377469 Viewed Jan 21, 2013)

Temperatures measured by the authors at the edge of the solar complex on the surface of a heliostat were approximately 200° Fahrenheit (~93° Celsius). Therefore, there is a gradient of temperature from the edge of the solar field to the tower that ranges from 200° to 900° Fahrenheit.

There is a phenomenon that occurs when the heliostats are focused on the tower and electricity is being generated. The phenomenon can be described as either a circle of clouds around the tower or, at times, a cloud formed on the side that is receiving the solar reflection. It appears as though the tower is creating clouds. Currently we propose two hypotheses of why this "cloud" is formed. The first hypothesis is simply the presumption that the high heat associated with towers is condensing the air, and forming the

Figure 9: Tower 1 (bright white) is shown under power. Tower 2 (black) is not operating.

clouds. The second hypothesis is that this phenomenon does not represent clouds at all rather it is a place in space where the heliostats that are not being used to generate heat are focused. Under this scenario, it is a place where the mirrors focus the excess energy not being used to generate electricity.

Ivanpah employees and OLE staff noticed that close to the periphery of the tower and within the reflected solar field area, streams of smoke rise when an object crosses the solar flux fields aimed at the tower. Ivanpah employees used the term “streamers” to characterize this occurrence.

When OLE staff visited the Ivanpah Solar plant, we observed many streamer events. It is claimed that these events represent the combustion of loose debris, or insects. Although some of the events are likely that, there were instances in which the amount of smoke produced by the ignition could only be explained by a larger flammable biomass such as a bird. Indeed OLE staff observed birds entering the solar flux and igniting, consequently becoming a streamer.

OLE staff observed an average of one streamer event every two minutes. It appeared that the streamer events occurred more frequently within the “cloud” area adjacent to the tower. Therefore we hypothesize that the “cloud” has a very high temperature that is igniting all material that traverses its field.
One possible explanation of this this phenomenon is that the “cloud” is a convergent location where heliostats are “parked” when not in use. Conversely it undermines the condensation hypothesis, given that birds flying through condensation clouds will not spontaneously ignite.

Temperatures required to burn feathers

Many of the carcasses recovered from the Ivanpah Solar plant after the plant became operational showed singing of feathers as shown in Figure 10.

Figure 10: Singed feathers from a Northern Rough-winged Swallow

In order to investigate at what temperature feathers burn/singe, we exposed feathers to different air temperatures. Each feather was exposed to a stream of helium and air for 30 seconds. The results indicate that at 400° Celsius (752° Fahrenheit) after 30 seconds the feather begins to degrade. But at 450° and

500° Celsius (842° and 932° Fahrenheit respectively) the feathers singed as soon as they made contact with the superheated air (Figure 11). Therefore, when singed birds are found, it can be inferred that the temperatures in the solar flux at the time a bird flew through it was at least 400° Celsius (752° Fahrenheit). This inference is consistent with the desired operating temperature of a power tower solar boiler (482° Celsius).

The fact that a bird will catch on fire as it flies through the solar flux has been confirmed by a Chevron engineer who works at the Coalinga Chevron Steam plant, a joint venture of Chevron and BrightSource Solar. (http://abclocal.go.com/kDSn/story?section=news%2Fbusiness&id=8377469 Viewed Jan 21, 2013)

Figure 11: Results of exposing feathers to different temperatures (in degrees Celsius)

Conclusions and Recommendations

In summary, three main causes of avian mortality were identified at these facilities; impact trauma, predation and solar flux. Birds at all three types of solar plants were susceptible to impact trauma and predators. Solar flux injury was unique to the power tower facility. Solar facilities, in general, do not appear to attract particular species, rather an ecological variety of birds are vulnerable. That said, certain mortality and species trends were evident, such as waterbirds at Desert Sunlight, where open water sources were present.

Specific hazards were identified, including vertically-oriented mirrors or other smooth reflective panels; water-like reflective or polarizing panels; actively fluxing towers; open bodies of water; aggregations of insects that attracted insectivorous birds; and resident predators. Making towers, ponds and panels less attractive or accessible to birds may mitigate deaths. Specific actions include placing perch-guards on power tower railings near the flux field, properly netting or otherwise covering ponds, tilting heliostat mirrors during washing and suspending power tower operation at peak migration times.

Visual cues should be retrofitted to existing panels and incorporated into new panel design. These cues may include UV-reflective or solid, contrasting bands spaced no further than 28 cm from each other. This arrangement has been shown to significantly reduce the number of passerines hitting expanses of windows on commercial buildings. Spacing of 10 cm eliminates window strikes altogether. Further exploration of panel design and orientation should be undertaken with researchers experienced in the field (Daneil Klem Jr. of Muhlenberg College) to determine causes for the high rate of impact trauma, and designs optimized to reduce these mortalities.

Challenges to data collection included rapid degradation of carcass quality hindering cause of death and species determination; large facilities which are difficult to efficiently search for carcasses; vegetation and panels obscuring ground visibility; carcass loss due to scavenging; and inconsistent documentation of carcass history. Searcher efficiency has been shown to have varying influences on carcass recovery with anywhere from 30% to 90% detection of small birds achieved in studies done at wind plants (Erickson et al., 2005). Scavengers may also remove substantial numbers of carcasses. In studies done on agricultural fields, up to 90% of small bird carcasses were lost within 24 hours (Balcomb, 1986; Wobeser and Wobeser, 1992). OLE staff observed apparently resident ravens at the Ivanpah power tower. Ravens are efficient scavengers, and could remove large numbers of small bird carcasses from the tower vicinity. (Erickson, W. P., G. D. Johnson, and D. P. Young, Jr., 2005, A summary and comparison of bird mortality from anthropogenic causes with an emphasis on collisions: U S Forest Service General Technical Report PSW, v. 191, p. 1029-1042; Balcomb, R., 1986, Songbird carcasses disappear rapidly from agricultural fields: Auk, v. 103, p. 817-820; Wobeser, G., and A. G. Wobeser, 1992, Carcass disappearance and estimation of mortality in a simulated die-off of small birds: Journal of Wildlife Diseases, v. 28, p. 548-554.)

Given these variables it is difficult to know the true scope of avian mortality at these facilities. The numbers of dead birds are likely underrepresented, perhaps vastly so. Observational and statistical studies to account for carcass loss may help us to gain a better sense of how many birds are being killed. Complete histories would help us to identify factors (such as vertical placement of mirrors) leading to mortalities. Continued monitoring is also advised as these facilities transition from construction to full operation. Of especial concern is the Ivanpah facility which was not fully-functioning at the time of the latest carcass submissions. In fact, all but 7 of the carcasses with solar flux injury and reported dates of collection were found at or prior to the USFWS site visit (October 21-24, 2013) and, therefore, represent flux mortality from a facility operating at only 33% capacity. Investigation into bat and insect mortalities at the power tower site should also be pursued.

ACKNOWLEDGMENTS

We wish to acknowledge the invaluable assistance and insights of S.A. Michael Clark and S.A. Ed Nieves.

Appendix 1. List of all 71 species recovered from the three solar energy sites. In this table, remains of closely related taxa that could not be definitively identified (e.g. Cinnamon/Blue-winged Teal and Black-throated/Sage Sparrow) are assigned to the biogeographically more likely taxon. In all such cases, the possible taxa are ecologically similar. All of these species are MBTA-listed.

Subject: Bird and Bat Conservation Strategy for the Desert Sunlight Solar Project in Riverside County, California

The U.S. Fish and Wildlife Service (Service) appreciates the continued coordination among the Renewable Energy Action Team (REAT) agencies on project-specific planning, environmental review, and development of compliance plans, including Bird and Bat Conservation Strategies (BBCS). The Bureau of Land Management (BLM) recently approved the BBCS for the Desert Sunlight Solar Project. We have provided substantive comments on several iterations of the draft BBCS that were not incorporated into the accepted version, and would like to highlight the importance of the monitoring program within the adaptive management[1] framework as a means of addressing and evaluating our stated concerns. As we learn more about the relationship between solar facilities and avian impacts, we anticipate the need for further refinement of this and other project-level BBCSs, as monitoring results and changing agency policy may warrant.

Because utility-scale solar development is a relatively nascent industry, systematic monitoring designed to assess the impacts associated with construction and operation of these types of facilities has not been conducted. Consequently, our current scientific understanding of the effects of all aspects of facility operations (e.g., noise, lighting, panels, utility lines, etc.) on bird and bat impacts, such as differential effects on behaviors and mortality rates of resident and migratory species, and changes in population status of those groups, is limited.

---

[1] Adaptive management is an iterative, science-based process that involves: (a) formulating alternative actions to meet measurable objectives; (b) predicting the outcomes of alternatives based on current knowledge; (c) monitoring to test the assumptions underlying those predictions; (d) implementing alternatives; (e), monitoring the results; and (f) using the monitoring results to improve knowledge and adjust actions and objectives accordingly.

The Service will participate in the Technical Advisory Group (TAG) that has been established for this project. Therefore, in preparation for the TAG process, we offer the following key components of the BBCS that will best help the REAT agencies better understand the risks to avian communities and how best to avoid and minimize impacts to migratory birds on this and other solar energy projects. Among other issues, we will ask that the TAG address the topics below as part of their responsibilities.

- The Desert Sunlight Solar Project will be one of the first utility-scale solar projects where systematic mortality monitoring will be conducted. Accordingly, the adaptive management section of the BBCS focuses on the mortality monitoring component of the plan; however, discussions regarding effectiveness monitoring of existing conservation measures and the identification of metrics or thresholds necessary to trigger implementation of additional conservation measures should be articulated in the plan. These types of metrics will be useful in addressing impacts that may not have been accounted for during the permitting process. We believe it will be important for the TAG to consider effectiveness monitoring in the adaptive management process to minimize adverse effects to the extent feasible.

- To our knowledge, distance sampling has never been used for this application (mortality monitoring on wind and solar projects). Due to site-specific conditions (obstructed visibility inherent to the project panel configuration), 100 percent of the proposed search area may not be adequately observed. Therefore, additional survey area may be needed to meet the stated objective to survey 30 percent of the solar field. The TAG should evaluate the results after each monitoring season and make recommendations to BLM to modify the methodology, if warranted.

- The BBCS establishes mixed monitoring intervals (7 and 21 days) for different seasons. Longer monitoring intervals are not supported by the Corvus carcass persistence trials performed on the Desert Sunlight site to date, HT Harvey's detectability study, and much of the available literature from the Mojave region. Longer survey intervals could introduce a bias toward larger bodied species, with medium and smaller sized species being under-represented. This bias could be further complicated by sampling only a subset of the fall and spring migration periods. Consequently, these intervals coupled with the distance sampling method as proposed, could result in statistically significant under-sampling, which cannot be corrected for using estimators. We suggest the TAG evaluate the methods and results in accordance with an agreed upon schedule as discussed below.

- There are over 400 species of resident and migratory birds known to occur in this region (Rosenberg et al. 1991, Patten et al. 2003). The migration periods specified in the BBCS are inadequate to cover the suite of species that have been documented in the area. We will work within the framework of the TAG to review a subset of avian species migratory patterns and make recommendations to adjust the migration monitoring periods, as appropriate, to avoid bias where possible, in the mortality monitoring results.

- Mortalities of rare species have been documented at this and other solar facilities in the California desert. Currently, the BBCS includes systematic monitoring of 30 percent of the solar field; however, this level of survey effort may not be sufficient to detect rare mortality events of uncommon and/or listed species, such as Yuma Ridgway's rail. New modeling tools, such as the Evidence of Absence tool (Huso *et al.* in press), have recently become available and can be used to inform what level of monitoring will be needed to increase the level of confidence that a rare mortality event has not occurred during the monitoring period. We recommend that the TAG assess whether the use of this tool should be used to inform future monitoring efforts.

- The BBCS allows the use of monitoring personnel who do not have academic ornithological and field ecology/biology background or personnel with limited experience in the desert Southwest. While training will be conducted, locating carcasses can be quite difficult, especially for surveyors unfamiliar with scientific principles, and measurements for distance sampling will need to be precise to support a robust analysis. An assessment of searcher efficiency rates and a complete description of methods [i.e., the number, size (weight), and species of trial carcasses used, exact time and location of carcass placement, surveyor detectability thresholds, etc.] should be reviewed periodically by the TAG to determine if modifications are warranted.

  Accurate identification of species is critical to understanding which species/taxa may be at risk from the project. We appreciate that an Authorized Avian Biologist will be available to ensure proper identification of carcasses and implementation of collection protocols and that a biologist will be on-site during monitoring periods to provide oversight. However, for carcasses and feathers that the Authorized Avian Biologist cannot identify, we would like to establish a process to have these items identified by a federally permitted natural history museum, ornithological research institution, or public wildlife forensic laboratory approved by the Service.

- As part of our efforts to gain a better understanding of cumulative impacts associated with solar projects throughout the desert region, biological samples from bird carcasses need to be collected. Identification of affected sub-populations of priority species is needed to help determine the significance of demographic impacts. Determination of the sub-species and regional populations affected require the collection of morphometric, genetic, and isotope data from collected carcasses (including those currently in storage on the project site).

One of the primary functions of an effective mortality monitoring program is to obtain the data necessary for the TAG to make informed decisions on the implementation and/or modification of conservation actions needed to reduce the impacts of mortality. Data are also needed to assist the TAG in determining the effectiveness of those conservation actions once they are adopted. We recommend that the TAG review the site-specific avoidance and minimization measures implemented to date by the project proponent, and assess whether effectiveness monitoring data could be collected to determine the utility of these and any future conservation actions.

The BBCS for Desert Sunlight states that the TAG meets subsequent to each monitoring season to review results of the carcass persistence, searcher efficiency, and mortality monitoring surveys. Seasonal meetings will allow the TAG to evaluate the concerns listed above and recommend any necessary adjustments to the monitoring methods prior to the next seasonal survey, if warranted and the meeting schedules allow.

We also recommend that an annual comprehensive report that includes mortality estimates for all birds and key taxa identified by the TAG, an analysis of meteorological data, taxa-specific migration information that may affect avian presence on and around the project site during the monitoring period, be submitted to the TAG after each full year of monitoring. The report should analyze the assumptions associated with the protocol, monitoring methods employed, and results that inform any conclusions. Based on a review of the report, the TAG may recommend continuation of the current protocol or recommend modifications to the methods to better achieve the monitoring goals and objectives.

We look forward to participating in the TAG and working together to develop and implement a meaningful adaptive management strategy that will facilitate conservation of our shared trust resources. If you have any questions regarding these comments or our recommendations, please contact Thomas Dietsch in our Division of Migratory Birds at thomas_dietsch@fws.gov; (760) 431-9440, extension 214 or Jody Fraser in the Palm Springs Fish and Wildlife Office at jody_fraser@fws.gov; (760) 322-2070, extension 207.

Avian Mortality at Solar Energy Facilities in Southern California: A Preliminary Analysis

Rebecca A. Kagan, Tabitha C. Viner, Pepper W. Trail, and Edgard O. Espinoza
National Fish and Wildlife Forensics Laboratory

Executive Summary

This report summarizes data on bird mortality at three solar energy facilities in southern California: Desert Sunlight, Genesis, and Ivanpah. These facilities use different solar technologies, but avian mortality was documented at each site. Desert Sunlight is a photovoltaic facility, Genesis employs a trough system with parabolic mirrors, and Ivanpah uses a power tower as a focal point for solar flux.

FINDINGS

Trauma was the leading cause of death documented for remains at the Desert Sunlight and Genesis sites. Trauma and solar flux injury were both major causes of mortality at the Ivanpah site. Exposure to solar flux caused singeing of feathers, which resulted in mortality in several ways. Severe singeing of flight feathers caused catastrophic loss of flying ability, leading to death by impact with the ground or other objects. Less severe singeing led to impairment of flight capability, reducing ability to forage and evade predators, leading to starvation or predation. Our examinations did not find evidence for significant tissue burns or eye damage caused by exposure to solar flux.

Cause of Death	Ivanpah	Genesis	Desert Sunlight	Total
Solar Flux	47	0	0	47
Impact trauma	24	6	19	49
Predation trauma	5	2	15	22
Trauma of undetermined cause	14	0	0	14
Electrocution	1	0	0	1
Emaciation	1	0	0	1
Undetermined (remains in poor condition)	46	17	22	85
No evident cause of death	3	6	5	14
Total	141	31	61	233

These solar facilities appear to represent "equal-opportunity" hazards for the bird species that encounter them. The remains of 71 species were identified, representing a broad range of ecological types. In body size, these ranged from hummingbirds to pelicans; in ecological type from strictly aerial feeders (swallows) to strictly aquatic feeders (grebes) to ground feeders (roadrunners) to raptors (hawks and owls). The species identified were equally divided among resident and non-resident species, and nocturnal as well as diurnal species were represented. Although not analyzed in detail, there was also significant bat and insect mortality at the Ivanpah site, including monarch butterflies. It appears that Ivanpah may act as a **"mega-trap,"** attracting insects which in turn attract insect-eating birds, which are incapacitated by solar flux injury, thus attracting predators and creating an entire food chain vulnerable to injury and death.

			Foraging Zone			**Residency Status**	
SITE	No. Remains	Identifiable Remains	Air	Terr	Water	Resident	Migrant
Ivanpah	141	127	28	85	14	63	64
Genesis	31	30	12	12	6	20	10
Desert Sun	61	56	7	22	27	18	38
TOTALS	233	213	47	119	47	101	112

CONCLUSIONS AND RECOMMENDATIONS

In summary, three main causes of avian mortality were identified at these facilities: impact trauma, solar flux, and predation. Birds at all three types of solar plants were susceptible to impact trauma and predators. Predation was documented mostly at the photovoltaic site, and in many cases appeared to be associated with stranding or nonfatal impact trauma with the panels, leaving birds vulnerable to resident predators. Solar flux injury, resulting from exposures to up to 800º F, was unique to the power tower facility. Our findings demonstrate that a broad ecological variety of birds are vulnerable to morbidity and mortality at solar facilities, though some differential mortality trends were evident, such as waterbirds at Desert Sunlight, where open water sources were present; and insectivores at Ivanpah, where insects are attracted to the solar tower.

Specific hazards were identified, including vertically-oriented mirrors or other smooth reflective panels; water-like reflective or polarizing panels; actively fluxing towers; open bodies of water; aggregations of insects that attracted insectivorous birds; and resident predators. Making towers, ponds and panels less attractive or accessible to birds may mitigate deaths. Specific actions should include:

Monitoring/detection measures:

1) Install video cameras sufficient to provide 360 degree coverage around each tower to record birds (and bats) entering and exiting the flux

2) For at least two years (and in addition to planned monitoring protocol), conduct daily surveys for birds (at all three facilities), as well as insects and bats (in the condenser building at Ivanpah) around each tower at the base of and immediately adjacent to the towers in the area cleared of vegetation. Timing of daily surveys can be adjusted to minimize scavenger removal of carcasses as recommended by the TAC. Surveys in the late afternoon might be optimal for bird carcasses, and first light for bat carcasses.

3) Use dogs for monitoring surveys to detect dead and injured birds that have hidden themselves in the brush, both inside and outside the perimeter of the facility

4) To decrease removal of carcasses, implement appropriate raven deterrent actions

Bird Mortality Avoidance Measures*:*

1) Increase cleared area around tower at Ivanpah to decrease attractive habitat; at least out to fence

2) Retrofit visual cues to existing panels at all three facilities and incorporate into new panel design. These cues should include UV-reflective or solid, contrasting bands spaced no further than 28 cm from each other

3) Suspend power tower operation during peak migration times for indicated species

4) Avoid vertical orientation of mirrors whenever possible, for example tilt mirrors during washing

5) Properly net or otherwise cover ponds

6) Place perch deterrent devices where indicated, eg. on tower railings near the flux field

7) Employ exclusionary measures to prevent bats from roosting in and around the condenser facility at Ivanpah.

It must be emphasized that we currently have a very incomplete knowledge of the scope of avian mortality at these solar facilities. Challenges to data collection include: large facilities which are difficult to efficiently search for carcasses; vegetation and panels obscuring ground visibility; carcass loss due to scavenging; rapid degradation of carcass quality hindering cause of death and species determination; and inconsistent documentation of carcass history.

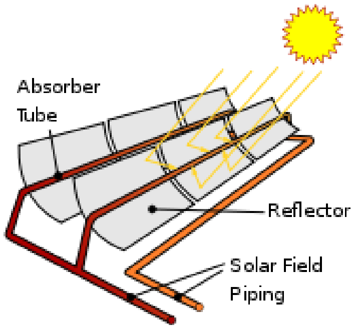
To rectify this problem, video cameras should be added to the solar towers to record bird mortality and daily surveys of the area at the base of and immediately adjacent to the towers should be conducted. At all the facilities, a protocol for systematic, statistically-rigorous searches for avian remains should be developed, emphasizing those areas where avian mortality is most likely to occur. Investigation into bat and insect mortalities at the power tower site should also be pursued.

Finally, there are presently little data available on how solar flux affects birds and insects. Studies of the temperatures experienced by objects in the flux; of the effects of high temperatures on feather structure and function; and of the behavior of insects and birds in response to the flux and related phenomena (e.g. “light clouds”) are all essential if we are to understand the scope of solar facility effects on wildlife.

Introduction

The National Fish and Wildlife Forensics Laboratory was requested to determine cause of death for birds found at facilities that generate electricity from solar energy. Solar generating facilities can be classified into three major types: photovoltaic sites, trough systems and solar power towers. There is much written about these systems so this report will not include any technical details, but simply mention the differences and their potential impact on birds.

1) **Photovoltaic systems** directly convert the sun's light into electricity. The perceived threat to birds is associated with the presence of water ponds which attract birds and from traumatic impact with the photovoltaic cells. An example of this type of solar power plant is Desert Sunlight Solar Farm (AKA First Solar).



2) **Trough systems** are composed of parabolic mirrors which focus and reflect the sun to a tube that converts the heat from the sun into electricity. The perceived threat to birds is associated with the presence of water ponds which attract birds and from traumatic impact with the trough structures. An example of this type of solar power plant is Genesis Solar Energy Project.

3) **Solar power towers** use thousands of mirrors to reflect the solar energy to a tower, where water in a boiler is converted to steam, generating the electricity. The perceived threat to birds is associated traumatic impact with the mirrors and the danger associated with the heat produced by the mirrors. An example of this type of solar power plant is Ivanpah Solar Electric Generating System.

Methods

Carcasses were collected at the different solar power plant sites by either US Fish and Wildlife Service employees or by energy company staff. The collection of the carcasses was opportunistic; that is, not according to a pre-determined sampling schedule or protocol. There was no attempt to quantify the number of carcasses that scavengers or predators removed from the solar facilities' grounds, or to compare the distribution of carcasses inside and outside the boundaries of the solar facility sites.

Additionally, three USFWS/-OLE staff, including two Forensics Lab staff (EOE and RAK), visited the Ivanpah Solar plant from October 21 – 24, 2013. Their on-site observations are included in this report.

A total of 233 birds collected from three different facilities were examined; 141 from a solar thermal power tower site (Ivanpah, Bright Source Inc.), 31 from a parabolic trough site (Genesis, NextEra Energy Inc.) and 61 from a photovoltaic (PV) panel site (Desert Sunlight, First Solar Inc.). Nine of the Ivanpah birds were received fresh; 7 of those were necropsied during a site visit by a Forensics Laboratory pathologist (RAK). The rest of the birds were received frozen and allowed to thaw at room temperature prior to species identification and necropsy. Species determination was made by the Forensics Laboratory ornithologist (PWT) for all birds either prior to necropsy or, for those necropsied on-site, from photos and the formalin-fixed head. All data on carcass history (location of the carcass, date of collection and any additional observations) were transcribed, although these were not available for all carcasses.

As part of the gross pathological examination, whole carcasses were radiographed to help evaluate limb fractures and identify any metal foreign bodies. Alternate light source examination using an Omnichrome Spectrum 9000+ at 570 nm with a red filter helped rule in or out feather burns by highlighting subtle areas of feather charring (Viner et al., 2014). All birds or bird parts from Ivanpah without obvious burns were examined with the alternate light source, as well as any bird reportedly found near a power line and a random sub-sample of the remaining birds from Genesis and Desert Sunlight (Viner, T. C., R. A. Kagan, and J. L. Johnson, 2014, Using an alternate light source to detect electrically singed feathers and hair in a forensic setting. Forensic Science International, v. 234, p. e25-e29).

Carcass quality varied markedly. If carcasses were in good post mortem condition, representative sections of heart, lung, kidney, liver, brain and gastrointestinal tract as well as any tissues with gross lesions were collected and fixed in 10% buffered formalin. Full tissue sets were collected from the fresh specimens. Formalin-fixed tissues were routinely processed for histopathology, paraffin-embedded, cut at 4 µm and stained with hematoxylin and eosin. Tissues from 63 birds were examined microscopically: 41 from Ivanpah, 1 from Genesis and 21 from Desert Sunlight.

Birds with feather burns were graded based on the extent of the lesions. Grade 1 birds had curling of less than 50% of the flight feathers. Grade 2 birds had curling of 50% or more of the flight feathers. Grade 3 birds had curling and visible charring of contour feathers (Figure 1).

Figure 1: Three grades of flux injury based on extent and severity of burning. Grade 1 (top); Yellow-rumped Warbler with less than 50% of the flight feathers affected (note sparing of the yellow rump feathers). Grade 2 (middle); Northern Rough-winged Swallow initially found alive but unable to fly, with greater than 50% of the flight feathers affected. Grade 3 (bottom); MacGillivray's Warbler with charring of feathers around the head, neck, wings and tail.

Bird Species Recovered at Solar Power Facilities

Tables 1-4 and Appendix 1 summarize 211 identifiable bird remains recovered from the three solar facilities included in this study. These birds constitute a taxonomically diverse assemblage of 71 species, representing a broad range of ecological types. In body size, these species ranged from hummingbirds to pelicans; in ecological type from strictly aerial feeders (e.g. swifts and swallows) to strictly aquatic feeders (pelicans and cormorants) to ground feeders (roadrunners) to raptors (hawks and owls). The species identified were equally divided among resident and non-resident species. Nocturnal as well as diurnal species were represented.

In Tables 1-4 and Appendix 1, bird species are categorized into very general ecological types by foraging zone and residency status. Foraging Zones were "air" (a significant portion of foraging activity performed in the air), "terrestrial" (including foraging both in vegetation and on the ground), and "water" (foraging associated with water, including waders as well as aquatic birds). Residency Status was "resident" (for breeding or year-round residents) and "migrant" (for both passage migrants and non-breeding-season residents). For a number of species, the appropriate classification for residency status was uncertain, due to a lack of detailed knowledge of the sites. The present classification is based on published range maps, and is subject to revision as more information becomes available.

This dataset is not suitable for statistical analysis, due to the opportunistic and unstandardized collection of avian remains at the facilities, and the lack of baseline data on bird diversity and abundance at each site. Nevertheless, a few conclusions can be noted. First, these data do not support the idea that these solar facilities are attracting particular species. Of the 71 bird species identified in remains, only five species were recovered from all three sites. These five were American Coot, Mourning Dove, Lesser Nighthawk, Tree Swallow, and Brown-headed Cowbird, again emphasizing the ecological variety of birds vulnerable to mortality at the solar facilities. Over two-thirds (67%) of the species were found at only a single site

(Appendix 1). That being said, the Desert Sunlight facility had particularly high mortality among waterbirds, suggesting a need to render the ponds at that site inaccessible or unattractive to these species.

The diversity of birds dying at these solar facilities, and the differences among sites, suggest that there is no simple "fix" to reduce avian mortality. These sites appear to represent "equal-opportunity" mortality hazards for the bird species that encounter them. Actions to reduce or mitigate avian mortality at solar facilities will need to be designed on a site-specific basis, and will require much more data on the bird communities at each site, and on how mortality is occurring. Carefully-designed mortality studies might reveal significant patterns of vulnerability that are not evident in these data.

Table 1. Summary data on avian mortality at the three solar sites included in this study. See summary for discussion of Foraging Zone and Residency Status categories.

				Foraging Zone			**Residency Status**

Cause of Death of Birds Found at the Solar Power Plants

Photovoltaic facility (Desert Sunlight):

Sixty-one birds from 33 separate species were represented from Desert Sunlight. Due to desiccation and scavenging, a definitive cause of death could not be established for 22 of the 61 birds (see Table 5). Feathers could be examined in all cases, however, and none of the 61 bird remains submitted from the PV facility had visible evidence of feather singeing, a clear contrast with birds found at Ivanpah.

Blunt force impact trauma was determined to have been the cause of death for 19 Desert Sunlight birds including two Western Grebes (*Aechmophorus occidentalis*) and one each of 16 other species. Impact (blunt force) trauma is diagnosed by the presence of fractures and internal and/or external contusions. In particular, bruising around the legs, wings and chest are consistent with crash-landings while fractures of the head and/or neck are consistent with high-velocity, frontal impact (such as may result from impacting a mirror).

Figure 2: Predation trauma (top) resulting in traumatic amputation of the head and neck (American Avocet) and impact trauma (bottom) causing bruising of the keel ridge of the sternum (Brown Pelican).

Predation was the immediate cause of death for 15 birds. Lesions supporting the finding of predation included decapitation or missing parts of the body with associated hemorrhage (9/15), and lacerations of the skin and pectoral muscles. Eight of the predated birds from Desert Sunlight were grebes, which are unable to easily take off from land. This suggests a link between predation and stranding and/or impact resulting from confusion of the solar panels with water (see Discussion).

Parabolic trough facility (Genesis):

Thirty-one birds were collected from this site. There were 15 species represented. Those found in the greatest numbers were Brown-headed Cowbirds and Cliff Swallows, though no more than 6 individuals from any given species were recovered. Overall, carcass quality was poor and precluded definitive cause of death determination in 17/31 birds (Table 5). Identifiable causes of death consisted of impact trauma (6/31) and predation trauma (2/31). Necropsy findings were similar to those at Desert Sunlight with fractures and hemorrhage noted grossly. Predation trauma was diagnosed in two birds, a Cliff Swallow and a Ring-billed Gull.

Power tower facility (Ivanpah):

Ivanpah is the only facility in this study that produces solar flux, which is intense radiant energy focused by the mirror array on the power-generating tower. Objects that pass through this flux, including insects and birds, encounter extreme heat, although the extent of heating depends on many variables, including the duration of exposure and the precise location in the flux beam.

From Ivanpah, 141 birds were collected and examined. Collection dates spanned a period of one year and five months (July 2012 to December 2013) and included at least seven months of construction during which time the towers were not actively fluxing (2013). There were 49 species represented (Table 4). Those found in the greatest numbers were Yellow-rumped Warblers (*Setophaga coronata;* 14), House Finches (*Carpodacus mexicanus*; 13), Mourning Doves (*Zenaida macroura*; 11) and American Coots (*Fulica americana*; 7). Yellow-rumped Warblers and House Finches were found exclusively at the power tower site.

Solar flux injury was identified as the cause of death in 47/141 birds. Solar flux burns manifested as feather curling, charring, melting and/or breakage and loss. Flight feathers of the tail and/or wings were invariably affected. Burns also tended to occur in one or more of the following areas; the sides of the body (axillae to pelvis), the dorsal coverts, the tops and/sides of the head and neck and the dorsal body wall (the back). Overlapping portions of feathers and light-colored feathers were often spared (Figures 3 and 4).

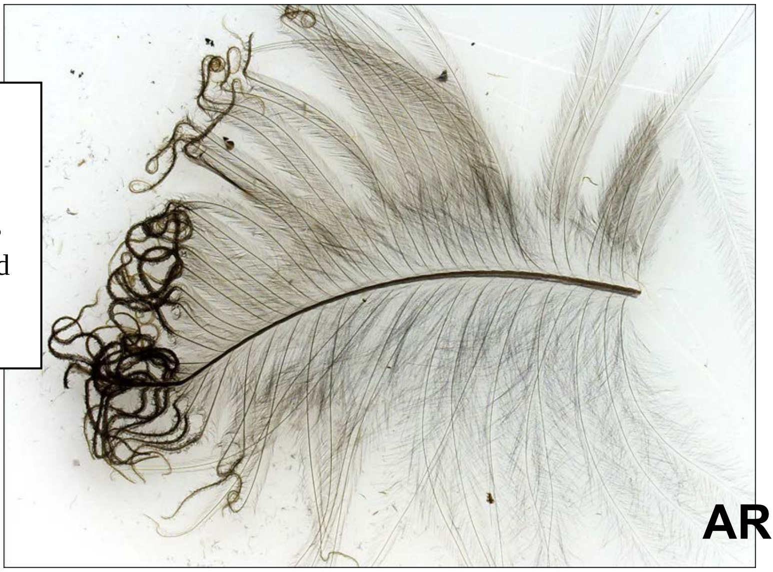

Figure 3: contour feather from the back of a House Finch with Grade 3 solar flux injury. The feather has curling and charring limited to the exposed tip.

Figure 4: Feather from a Peregrine Falcon with Grade 2 solar flux injury. Note burning of dark feather bands with relative sparing of light bands.

The yellow and red rumps of Yellow-rumped Warblers and House Finches respectively remained strikingly unaffected (See Figure 1). Charring of head feathers, in contrast, was generally diffuse across all color patterns. A pattern of spiraling bands of curled feathers across or around the body and wings was often apparent.

Table 5. Cause of death (COD) data

Cause of Death	Ivanpah	Genesis	Desert Sunlight	Total
Solar Flux	47	0	0	47
Impact trauma	24	6	19	49
Predation trauma	5	2	15	22
Trauma of undetermined cause	14	0	0	14
Electrocution	1	0	0	1
Emaciation	1	0	0	1
Undetermined (remains in poor condition)	46	17	22	85
No evident cause of death	3	6	5	14
Total	141	31	61	233

Eight birds were assigned a feather damage Grade of 1 with curling of less than 50% of the flight feathers. Six of these had other evidence of acute trauma (75%). Five birds were Grade 2, including three birds that were found alive and died shortly afterwards. Of these birds, 2 (the birds found dead) also had evidence of acute trauma. Twenty-eight birds were Grade 3; with charring of body feathers. Of these birds, 21/28

(28%) had other evidence of acute trauma. Remaining carcasses (6) were incomplete and a grade could not be assigned.

Twenty-nine birds with solar flux burns also had evidence of impact trauma. Trauma consisted of skull fractures or indentations (8), sternum fractures (4), one or more rib fractures (4), vertebral fractures (1), leg fracture (3), wing fracture (1) and/or mandible fracture (1). Other signs of trauma included acute macroscopic and/or microscopic internal hemorrhage. Location found was reported for 39 of these birds; most of the intact carcasses were found near or in a tower. One was found in the inner heliostat ring and one was found (alive) on a road between tower sites. The date of carcass collection was provided for 42/47. None were found prior to the reported first flux (2013).

Figure 5: The dorsal aspect of the wing from a Peregrine Falcon (the same bird as shown in Figure 4) with Grade 2 lesions. Note extensive curling of feathers without visible charring. This bird was found alive, unable to fly, emaciated and died shortly thereafter. These findings demonstrate fatal loss of function due to solar flux exposure in the absence of skin or other soft tissue burns.

Among the solar flux cases, a variety of bird species were affected though all but one (a raptor) was a passerine (Appendix 2). House Finches and yellow-rumped Warblers were most often represented (10/47 and 12/47 respectively). For the birds in which species could be determined (41/47), insects were a major dietary component in all but two species. These were an unidentified hummingbird (*Selasphorus*) species (known to include insects in the diet) and a Peregrine Falcon (a species that feeds on small birds).

Four birds were reportedly found alive and taken to a wildlife rehabilitation center where they died one to a few days later (exact dates were not consistently provided). Three had Grade 2 feather burns and one had Grade 3 feather burns. None had other evidence of trauma. Body condition was reduced in all of the birds (two considered thin and two emaciated) based on a paucity of fat stores and depletion of skeletal muscling. The four birds were of four different species and consisted of three passerines and one raptor.

The second most commonly diagnosed cause of death at the Ivanpah facility was impact (or blunt force) trauma (24/141 birds). Necropsy findings were as previously described at the Desert Sunlight facility. Impact marks were reported on heliostat mirrors adjacent to the carcasses in 5 cases and mirrors were described as being vertically-oriented in 5 cases. Specific carcass locations were reported for 18 of the birds. Those birds were found in a variety of areas; below heliostats (8/18), in or near tower and powerblock buildings (4/18), on roads (2/18), below power lines (2/18), in the open (1/18) and by a desert tortoise pen (1/18).

Predation was determined to be the cause of death for five of the birds. A coot and a Mourning Dove were found with extensive trauma and hemorrhage to the head and upper body consisting of lacerations, crush trauma and/or decapitation. One of the birds (an American Coot) was found near a kit fox shelter site. One bird (Northern Mockingbird) was found near the fence line and the third (a Mourning Dove) in an alley way. Two more birds (an unidentified sparrow and an American Pipit) were observed being eaten by one of the resident Common Ravens.

Discussion of Cause of Death of Birds Found at the Solar Power Plants

Impact trauma:

Sheet glass used in commercial and residential buildings has been well-established as a hazard for birds, especially passerines (Klem 1990, 2004, 2006; Loss et al. 2014). A recent comprehensive review estimated that between 365-988 million birds die annually by impacting glass panels in the United States alone (median estimate 599 million; Loss et al. 2014). Conditions that precipitate window strike events include the positioning of vegetation on either side of the glass and the reflective properties of the window. Glass panels that reflect trees and other attractive habitat are involved in a higher number of bird collisions.

The mirrors and photovoltaic panels used at all three facilities are movable and generally directed upwardly, reflecting the sky. At the Ivanpah facility, when heliostats are oriented vertically (typically for washing or installation, personal communication, RAK) they appear to pose a greater risk for birds. Of the eight birds reported found under a heliostat, heliostats were vertically-oriented in at least 5 cases. (D Klem Jr., DC Keck, KL Marty, AJ Miller Ball, EE Niciu, and CT Platt. 2004. Effects of window angling, feeder placement, and scavengers on avian mortality at plate glass. Wilson Bulletin, 116(1):69-73; D Klem Jr. 2006. Glass: A deadly conservation issue for birds. Bird Observer 34(2):73-81; D Klem Jr. 1990.

Collisions between birds and windows: mortality and prevention. Journal of Field Ornithology 61:120–128; Loss, S.R., T. Will, S.S.Loss, and P.P. Marra. 2014. Bird-building collisions in the United States: Estimates of annual mortality and species vulnerability. Condor 116: 8-23). Studies with aquatic insects have found that vertically-oriented black glass surfaces (similar to solar panels) produced highly polarized reflected light, making them highly attractive (Kriska, G., P. Makik, I. Szivak, and G. Horvath. 2008. Glass buildings on river banks as “polarized light traps” for mass-swarming polarotactic caddis flies. Naturwissenschaften 95: 461-467).

A desert environment punctuated by a large expanse of reflective, blue panels may be reminiscent of a large body of water. Birds for which the primary habitat is water, including coots, grebes, and cormorants, were over-represented in mortalities at the Desert Sunlight facility (44%) compared to Genesis (19%) and Ivanpah (10%). Several factors may inform these observations. First, the size and continuity of the panels differs between facilities. Mirrors at Ivanpah are individual, 4 x 8’ panels that appear from above as stippling in a desert background (Figure 6). Photovoltaic panels at Desert Sunlight are long banks of adjacent 27.72 x 47.25” panels (70 x 120 cm), providing a more continuous, sky/water appearance. Similarly, troughs at Genesis are banks of 5 x 5.5’ panels that are up to 49-65 meters long.

Figure 6: The Ivanpah Solar Electric Generating System as seen via satellite. The mirrored panels are 5 x 8 feet.

There is growing concern about “polarized light pollution” as a source of mortality for wildlife, with evidence that photovoltaic panels may be particularly effective sources of polarized light in the environment (see Horvath et al. 2010. Reducing the maladaptive attractiveness of solar panels to polarotactic insects. Conservation Biology 24: 1644-1653, and ParkScience, Vol. 27, Number 1, 2010; available online at: http://www.nature.nps.gov/parkscience/index.cfm?ArticleID=386&ArticleTypeID=5; as well as discussion of this issue in the Desert Sunlight Final Environmental Impact Statement, Chapter 4, pp. 14-15).

Variables that may affect the illusory characteristics of solar panels are structural elements or markings that may break up the reflection. Visual markers spaced at a distance of 28 cm or less have been shown to reduce the number of window strike events on large commercial buildings (City of Toronto Green Development Standard; Bird-friendly development guidelines. March 2007). Mirrors at the Ivanpah facility are unobscured by structures or markings and present a diffuse, reflective surface. Photovoltaic panels at Desert Sunlight are arranged as large banks of small units that are 60 x 90 cm. The visually uninterrupted expanse of both these types of heliostat is larger than that which provides a solid structure visual cue to passerines. Parabolic troughs at Genesis have large, diffusely reflective surfaces between seams that periodically transect the bank of panels at 5.5’ intervals. Structures within the near field, including the linear concentrator and support arms, and their reflection in the panels and may provide a visual cue to differentiate the panel as a solid structure.

The paper by Horvath et al cited above provides experimental evidence that placing a white outline and/or white grid lines on solar panels significantly reduced the attractiveness of these panels to aquatic insects, with a loss of only 1.8% in energy-producing surface area (p. 1651). While similar detailed studies have yet to be carried out with birds, this work, combined with the window strike results, suggest that significant reductions in avian mortality at solar facilities could be achieved by relatively minor modifications of panel and mirror design. This should be a priority for further research.

Finally, ponds are present on the property of the Desert Sunlight and Genesis facilities. The pond at Genesis is netted, reducing access by migratory birds, while the pond at Desert Sunlight is open to flighted wildlife. Thus, birds are both attracted to the water feature at Desert Sunlight and habituated to the presence of an accessible aquatic environment in the area. This may translate into the misinterpretation of a diffusely reflected sky or horizonal polarized light source as a body of water.

Stranding and Predation:

Predation is likely linked to panel-related impact trauma and stranding. Water birds were heavily over-represented in predation mortalities at Desert Sunlight. Of the 15 birds that died due to predation, 14 make their primary habitat on water (coots, grebes, a cormorant, and an avocet). A single White-winged Dove was the only terrestrial-based predation mortality in the submitted specimens. This is in contrast to blunt trauma mortalities at Desert Sunlight in which 8 of the 19 birds determined to have died of impact trauma were water species.

Locations of the birds when found dead were noted on several submissions. Of the birds that died of predation for which locations were known, none were located near ponds. The physiology of several of these water birds is such that locomotion on land is difficult or impossible. Grebes in particular have very limited mobility on land and require a run across water in order to take off (Jehl, J. R., 1996. Mass mortality events of Eared Grebes in North America. Journal of Field Ornithology 67: 471-476). Thus, these birds likely did not reach their final location intentionally. Ponds at the PV and trough sites are fenced, prohibiting terrestrial access by predators. Birds on the water or banks of the pond are inaccessible to resident predators. Therefore, it is unlikely that the birds were captured at the pond and transported by a predator into the area of the panels. Attempts to land or feed on the panels because of their deceptive appearance may have injured the birds to the point that they could not escape to safety, or inadvertently stranded the birds on a substrate from which they could not take flight. We believe that an inability to quickly flee after striking the panels and stranding on the ground left these birds vulnerable to opportunistic predators. At least two types of predators, kit foxes and ravens, have been observed in residence at the power tower and PV facilities and ravens have been reported at the trough site (personal communication and observation, RAK). Additionally, histories for multiple birds found at the tower site document carcasses found near kit fox shelters or being eaten or carried by a raven.

Solar Flux:

Avian mortality due to exposure to solar flux has been previously explored and documented (McCrary, M. D., McKernan, R. L., Schreiber, R. W., Wagner, W. D., and Sciarrotta, T. C. Avian mortality at a solar energy power plant. Journal of Field Ornithology, 57(2): 135-141). Solar flux injury to the birds of this report, as expected, occurred only at the power tower facility. Flux injury grossly differed from other sources of heat injury, such as electrocution or fire. Electrocution injury requires the bridging of two contact points and is, therefore, seen almost exclusively in larger birds such as raptors. Contact points tend to be on the feet, carpi and/or head and burns are often found in these areas. Electrocution causes deep tissue damage as opposed to the surface damage of fire or solar flux. Other sequelae include amputation of limbs with burn marks on bone, blood vessel tears and pericardial hemorrhage. Burns from fires cause widespread charring and melting of feathers and soft tissues and histopathologic findings of soot inhalation or heat damage to the respiratory mucosa. None of these were characteristics of flux injury. In the flux cases small birds were over-represented, had burns generally limited to the feathers and internal injuries attributable to impact. Flux injury inconsistently resulted in charring, tended to affect feathers along the dorsal aspects of the wings and tail, and formed band-like patterns across the body (Divincenti, F. C., J. A. Moncrief, and B. A. Pruitt. 1969. Electrical injuries: a review of 65 cases. The Journal of Trauma 9: 497-507).

Proposed mechanisms of solar flux-related death follow one or a combination of the following pathways:

- impact trauma following direct heat damage to feathers and subsequent loss of flight ability
- starvation and/or thermoregulatory dysfunction following direct heat damage to feathers
- shock
- soft tissue damage following whole-body exposure to high heat
- ocular damage following exposure to bright light.

Necropsy findings from this study are most supportive of the first three mechanisms.

Loss of feather integrity has effects on a bird's ability to take off, land, sustain flight and maneuver. Tail feathers are needed for lift production and maneuverability, remiges are needed for thrust and lift and feathers along the propatagium and coverts confer smoothness to the avian airfoil. Shortening of primary flight feathers by as little as 1.6 cm with loss of secondary and tertiary remiges has been shown to eliminate take-off ability in house sparrows further demonstrating the importance of these feathers (Brown, R. E., and A. C. Cogley, 1996. Contributions of the propatagium to avian flight: Journal of Experimental Zoology 276: 112-124). Loss of relatively few flight feathers can, therefore, render a bird unable or poorly-able to fly. Birds encountering the flux field at Ivanpah may fall as far as 400 feet after feather singeing. Signs of impact trauma were often observed in birds with feather burns and are supportive of sudden loss of function (Beaufrere, H., 2009. A review of biomechanic and aerodynamic considerations of the avian thoracic limb. Journal of Avian Medicine and Surgery 23: 173-185).

Birds appear to be able to survive flux burns in the short term, as evidenced by the collection of several live birds with singed feathers. Additionally, Forensic Lab staff observed a falcon or falcon-like bird with a plume of smoke arising from the tail as it passed through the flux field. Immediately after encountering the flux, the bird exhibited a controlled loss of stability and altitude but was able to cross the perimeter fence before landing. The bird could not be further located following a brief search (personal observation, RAK and EOE). Birds that initially survive the flux exposure and are able to glide to the ground or a perch may be disabled to the point that they cannot efficiently acquire food, escape predators or thermoregulate. Observations of emaciation in association with feather burns in birds found alive is supportive of debilitation subsequent to flux exposure. More observational studies and follow-up are required to understand how many birds survive flux exposure and whether survival is always merely short-term. As demonstrated by the falcon, injured birds (particulary larger birds), may be ambulatory enough to glide or walk over the property line indicating a need to include adjacent land in carcass searches.

There was evidence of acute skin burns on the heads of some of the Grade 3 birds that were found dead. But interestingly, tissue burn effects could not be demonstrated in birds known to have survived short periods after being burned. Hyperthermia causing instantaneous death manifests as rapid burning of tissue, but when death occurs a day or later there will be signs of tissue loss, inflammation, proteinic exudate and/or cellular death leading to multisystemic organ failure. The beginnings of an inflammatory response to injury can be microscopically observed within one to a few hours after the insult and would have been expected in any of the four birds found alive. Signs of heat stroke or inhalation of hot air should have been observable a day or more after the incident. Rather, in these cases extensive feather burns on the body largely appeared to be limited to the tips of the feathers with the overlapping portions insulating the body as designed. This, in conjunction with what is likely only a few seconds or less spent in the flux, suggests that skin or internal organ damage from exposure to high temperatures in solar flux may not be a major cause of the observed mortality.

Ocular damage following light exposure was also considered but could not be demonstrated in the submitted birds. In the four birds that initially survived, there were no signs of retinal damage, inflammation or other ocular trauma. Given the small sample size, this does not preclude sight impairment as a possible sequela but clinical monitoring of survivors would be needed to draw more definitive conclusions.

Other/Undetermined:

Powerline electrocution was the cause of death for one bird (a juvenile Common Raven) at the Ivanpah facility. Electrocution at these solar facilities is a potential hazard but, thus far, appears to be an uncommon cause of death.

Smashed birds (13/233) were found at all three locations. Detailed carcass collection information was provided for 6; all were found on roads. Though poor carcass quality in all cases precluded definitive cause death determination, circumstances and carcass condition suggest vehicle trauma as the cause of deaths. The relatively low numbers of vehicle collisions may be attributed to slow on-site vehicle speeds and light traffic. Vehicle collisions, therefore, do not appear to be a major source of mortality and would be expected to decrease as construction ends.

There was a large number of birds (85/233) for which a cause of death could not be determined due to poor carcass condition. The arid, hot environment at these facilities leads to rapid carcass degradation which greatly hinders pathology examination. Results were especially poor for birds from the Genesis facility, where the cause of death(s) for 23/31 (74%) could not be determined. These results underscore the need for carcasses to be collected soon after death. More frequent, concerted carcass sweeps are advised.

Insect mortality and solar facilities as “mega-traps”

An ecological trap is a situation that results in an animal selecting a habitat that reduces its fitness relative to other available habitats (Robertson, B.A. and R.L. Hutto. 2006. A framework for understanding ecological traps and an evaluation of existing evidence. Ecology 87: 1075-1085; Robertson, B.A., J.S. Rehage, and Sih, A. 2013. Ecological novelty and the emergence of evolutionary traps. Trends in Ecology and Evolution 28: 552-560).

A wide variety of circumstances may create ecological traps, ranging from subtle (songbirds attracted to food resources in city parks, where they are vulnerable to unnaturally high populations of predators) to direct (birds are attracted to oil-filled ponds, believing it to be water, and become trapped). It appears that solar flux facilities may act as **“mega-traps,”** which we define as artificial features that attract and kill species of multiple trophic layers. The strong light emitted by these facilities attract insects, which in turn attract insect-eating birds, which are incapacitated by solar flux injury, thus attracting predators and creating an entire food chain vulnerable to injury and death.

OLE staff observed large numbers of insect carcasses throughout the Ivanpah site during their visit. In some places there were hundreds upon hundreds of butterflies (including monarchs, *Danaus plexippus*) and dragonfly carcasses. Some showed singeing, and many appeared to have just fallen from the sky. Careful observation with binoculars showed the insects were active in the bright area around the boiler at the top of the tower. It was deduced that the solar flux creates such a bright light that it is brighter than the surrounding daylight. Insects were attracted to the light and could be seen actively flying the height of the tower. Birds were also observed feeding on the insects. At times birds flew into the solar flux and ignited. Bird carcasses recovered from the site showed the typical singed feathers. The large populations of insects may also attract indigenous bat species, which were seen roosting in structures at the base of the power tower.

Monarch butterflies in North America – both east and west of the Rocky Mountains – have been documented to be in decline (see the North American Monarch Conservation Plan, available at: http://www.mlmp.org/Resources/pdf/5431_Monarch_en.pdf). Proposed causes include general habitat loss and specific loss of milkweed, upon which the butterflies feed and reproduce. Considering the numerous monarch butterfly carcasses seen at the Ivanpah facility, it appears that solar power towers could have a significant impact on monarch populations in the desert southwest. Analysis of the insect mortality at Ivanpah, and systematic observations of bird/insect interactions around the power tower, is clearly needed.

Bird species affected by solar flux include both insectivores (e.g. swallows, swifts, flycatchers, and warblers) and raptors that prey on insect-feeding birds. Based on observations of the tower in flux and the finding of large numbers of butterflies, dragonflies and other insects at the base of the tower and in adjacent buildings it is suspected that the bright light generated by solar flux attracts insects, which in turn attracts insectivores and predators of insectivores. Waterbirds and other birds that feed on vegetation were not found to have solar flux burns. Birds were observed perching and feeding on railings at the top of the tower, apparently in response to the insect aggregations there.

Further, dead bats found at the Ivanpah site could be attracted to the large numbers of insects in the area. Nineteen bats from the condenser area of the power tower facility have been submitted to NFWFL for further evaluation. These bats belong to the Vespertilionidae and Molossidae families, which contain species considered by the Bureau of Land Management to be sensitive species in California. Preliminary evaluation revealed no apparent singing of the hair, and analysis is ongoing.

Solar flux and heat associated with solar power tower facilities

Despite repeated requests, we have been unsuccessful in obtaining technical data relating to the temperature associated with solar flux at the Ivanpah facility. The following summarizes the information we have gathered from other sources.

The Ivanpah solar energy generating facility consists of mirrors that reflect sunlight to a tower. In the tower sits a boiler that generates steam which then powers a turbine.

Figure 7 Ivanpah solar power facilities
http://ivanpahsolar.com/about

At the top of a 459 foot tall tower sits a boiler (solar receiver) that is heated by the sun rays reflected by 300,000 mirrors, called solar heliostats. When the concentrated sunlight strikes the boiler tubes, it heats the water to create superheated steam. The high temperature steam is then piped from the boiler to a turbine where electricity is generated (http://ivanpahsolar.com/about visited on 01/20/2014).

Figure 8: Seville solar power facility (http://inhabitat.com/sevilles-solar-power-tower)

If all the solar heliostats are focused on the solar tower the beams multiply the strength of sunlight by 5000 times, and this generates temperatures at the solar tower in excess of 3600° Fahrenheit (> 1982° Celsius). Since steel melts at 2750° Fahrenheit (1510° Celsius), only a percentage of heliostats are focused on the solar receiver so that) the optimal temperature at the tower is approximately 900° Fahrenheit (~482° Celsius) ("How do they do it" Wag TV for Discovery Channel, Season 3, Episode 15, "Design Airplane Parachutes, Create Solar Power, Make Sunglasses" Aired August 25, 2009).

A solar steam plant in Coalinga that also uses heliostat technology for extracting oil is on record stating that the steam generator is set to about 500° Celsius. (http://abclocal.go.com/kDSn/story?section=news%2Fbusiness&id=8377469 Viewed Jan 21, 2013)

Temperatures measured by the authors at the edge of the solar complex on the surface of a heliostat were approximately 200° Fahrenheit (~93° Celsius). Therefore, there is a gradient of temperature from the edge of the solar field to the tower that ranges from 200° to 900° Fahrenheit.

There is a phenomenon that occurs when the heliostats are focused on the tower and electricity is being generated. The phenomenon can be described as either a circle of clouds around the tower or, at times, a cloud formed on the side that is receiving the solar reflection. It appears as though the tower is creating clouds. Currently we propose two hypotheses of why this "cloud" is formed. The first hypothesis is simply the presumption that the high heat associated with towers is condensing the air, and forming the

Figure 9: Tower 1 (bright white) is shown under power. Tower 2 (black) is not operating.

clouds. The second hypothesis is that this phenomenon does not represent clouds at all rather it is a place in space where the heliostats that are not being used to generate heat are focused. Under this scenario, it is a place where the mirrors focus the excess energy not being used to generate electricity.

Ivanpah employees and OLE staff noticed that close to the periphery of the tower and within the reflected solar field area, streams of smoke rise when an object crosses the solar flux fields aimed at the tower. Ivanpah employees used the term “streamers” to characterize this occurrence.

When OLE staff visited the Ivanpah Solar plant, we observed many streamer events. It is claimed that these events represent the combustion of loose debris, or insects. Although some of the events are likely that, there were instances in which the amount of smoke produced by the ignition could only be explained by a larger flammable biomass such as a bird. Indeed OLE staff observed birds entering the solar flux and igniting, consequently becoming a streamer.

OLE staff observed an average of one streamer event every two minutes. It appeared that the streamer events occurred more frequently within the “cloud” area adjacent to the tower. Therefore we hypothesize that the “cloud” has a very high temperature that is igniting all material that traverses its field.
One possible explanation of this this phenomenon is that the “cloud” is a convergent location where heliostats are “parked” when not in use. Conversely it undermines the condensation hypothesis, given that birds flying through condensation clouds will not spontaneously ignite.

Temperatures required to burn feathers

Many of the carcasses recovered from the Ivanpah Solar plant after the plant became operational showed singing of feathers as shown in Figure 10.

Figure 10: Singed feathers from a Northern Rough-winged Swallow

In order to investigate at what temperature feathers burn/singe, we exposed feathers to different air temperatures. Each feather was exposed to a stream of helium and air for 30 seconds. The results indicate that at 400° Celsius (752° Fahrenheit) after 30 seconds the feather begins to degrade. But at 450° and

500° Celsius (842° and 932° Fahrenheit respectively) the feathers singed as soon as they made contact with the superheated air (Figure 11). Therefore, when singed birds are found, it can be inferred that the temperatures in the solar flux at the time a bird flew through it was at least 400° Celsius (752° Fahrenheit). This inference is consistent with the desired operating temperature of a power tower solar boiler (482° Celsius).

The fact that a bird will catch on fire as it flies through the solar flux has been confirmed by a Chevron engineer who works at the Coalinga Chevron Steam plant, a joint venture of Chevron and BrightSource Solar. (http://abclocal.go.com/kDSn/story?section=news%2Fbusiness&id=8377469 Viewed Jan 21, 2013)

Figure 11: Results of exposing feathers to different temperatures (in degrees Celsius)

Conclusions and Recommendations

In summary, three main causes of avian mortality were identified at these facilities; impact trauma, predation and solar flux. Birds at all three types of solar plants were susceptible to impact trauma and predators. Solar flux injury was unique to the power tower facility. Solar facilities, in general, do not appear to attract particular species, rather an ecological variety of birds are vulnerable. That said, certain mortality and species trends were evident, such as waterbirds at Desert Sunlight, where open water sources were present.

Specific hazards were identified, including vertically-oriented mirrors or other smooth reflective panels; water-like reflective or polarizing panels; actively fluxing towers; open bodies of water; aggregations of insects that attracted insectivorous birds; and resident predators. Making towers, ponds and panels less attractive or accessible to birds may mitigate deaths. Specific actions include placing perch-guards on power tower railings near the flux field, properly netting or otherwise covering ponds, tilting heliostat mirrors during washing and suspending power tower operation at peak migration times.

Visual cues should be retrofitted to existing panels and incorporated into new panel design. These cues may include UV-reflective or solid, contrasting bands spaced no further than 28 cm from each other. This arrangement has been shown to significantly reduce the number of passerines hitting expanses of windows on commercial buildings. Spacing of 10 cm eliminates window strikes altogether. Further exploration of panel design and orientation should be undertaken with researchers experienced in the field (Daneil Klem Jr. of Muhlenberg College) to determine causes for the high rate of impact trauma, and designs optimized to reduce these mortalities.

Challenges to data collection included rapid degradation of carcass quality hindering cause of death and species determination; large facilities which are difficult to efficiently search for carcasses; vegetation and panels obscuring ground visibility; carcass loss due to scavenging; and inconsistent documentation of carcass history. Searcher efficiency has been shown to have varying influences on carcass recovery with anywhere from 30% to 90% detection of small birds achieved in studies done at wind plants (Erickson et al., 2005). Scavengers may also remove substantial numbers of carcasses. In studies done on agricultural fields, up to 90% of small bird carcasses were lost within 24 hours (Balcomb, 1986; Wobeser and Wobeser, 1992). OLE staff observed apparently resident ravens at the Ivanpah power tower. Ravens are efficient scavengers, and could remove large numbers of small bird carcasses from the tower vicinity. (Erickson, W. P., G. D. Johnson, and D. P. Young, Jr., 2005, A summary and comparison of bird mortality from anthropogenic causes with an emphasis on collisions: U S Forest Service General Technical Report PSW, v. 191, p. 1029-1042; Balcomb, R., 1986, Songbird carcasses disappear rapidly from agricultural fields: Auk, v. 103, p. 817-820; Wobeser, G., and A. G. Wobeser, 1992, Carcass disappearance and estimation of mortality in a simulated die-off of small birds: Journal of Wildlife Diseases, v. 28, p. 548-554.)

Given these variables it is difficult to know the true scope of avian mortality at these facilities. The numbers of dead birds are likely underrepresented, perhaps vastly so. Observational and statistical studies to account for carcass loss may help us to gain a better sense of how many birds are being killed. Complete histories would help us to identify factors (such as vertical placement of mirrors) leading to mortalities. Continued monitoring is also advised as these facilities transition from construction to full operation. Of especial concern is the Ivanpah facility which was not fully-functioning at the time of the latest carcass submissions. In fact, all but 7 of the carcasses with solar flux injury and reported dates of collection were found at or prior to the USFWS site visit (October 21-24, 2013) and, therefore, represent flux mortality from a facility operating at only 33% capacity. Investigation into bat and insect mortalities at the power tower site should also be pursued.

ACKNOWLEDGMENTS

We wish to acknowledge the invaluable assistance and insights of S.A. Michael Clark and S.A. Ed Nieves.

Appendix 1. List of all 71 species recovered from the three solar energy sites. In this table, remains of closely related taxa that could not be definitively identified (e.g. Cinnamon/Blue-winged Teal and Black-throated/Sage Sparrow) are assigned to the biogeographically more likely taxon. In all such cases, the possible taxa are ecologically similar. All of these species are MBTA-listed.

SPECIES		**Zone**	**Residency**	**Sites**	**MNI**
Cinnamon Teal	*Anas cyanoptera*	water	migrant	DS,IV	5
Pied-billed Grebe	*Podilymbus podiceps*	water	migrant	DS	1
Western Grebe	*Aechmorphorus occidentalis*	water	migrant	DS	9
Eared Grebe	*Podiceps nigricollis*	water	migrant	DS,GN	5
Brown Pelican	*Pelecanus occidentalis*	water	migrant	DS	2
Double-crested Cormorant	*Phalacrocorax auritus*	water	migrant	DS	2
Great Blue Heron	*Ardea herodias*	water	migrant	GN	1
Black-crowned Night-Heron	*Nycticorax nycticorax*	water	migrant	DS	1
Cooper's Hawk	*Accipiter cooperii*	air	migrant	IV	1
Red-shouldered Hawk	*Buteo lineatus*	terr	migrant	IV	1
American Kestrel	*Falco sparverius*	air	resident	GN,IV	2
Peregrine Falcon	*Falco peregrinus*	air	resident	IV	1
American Coot	*Fulica americana*	water	migrant	DS, IV	12
Yuma Clapper Rail	*Rallus longirostris yumanensis*	water	resident	DS	1
Sora	*Porzana carolina*	water	migrant	DS,IV	2
American Avocet	*Recurvirostra americana*	water	migrant	DS	1
Spotted Sandpiper	*Actitis maculatus*	water	migrant	IV	2
Ring-billed Gull	*Larus delawarensis*	water	migrant	GN	2
California Gull	*Larus californianus*	water	resident	GN	1
Greater Roadrunner	*Geococcyx californianus*	terr	resident	IV	5
Yellow-billed Cuckoo	*Coccyzus americanus*	terr	migrant	IV	1
Mourning Dove	*Zenaida macroura*	terr	resident	DS, IV	14
White-winged Dove	*Zenaida asiatica*	terr	resident	DS,GN	2
Barn Owl	*Tyto alba*	terr	resident	IV	1
Lesser nighthawk	*Chordeiles acutipennis*	air	resident	DS,GN,IV	7
Common Poorwill	*Phalaenoptilus nuttallii*	air	resident	DS,IV	2
White-throated Swift	*Aeronautes saxatalis*	air	resident	IV	1
Costa's Hummingbird	*Calypte costae*	air	resident	DS	1
Allen's/Rufous Hummingbird	*Selasphorus sp.*	air	migrant	IV	1
Northern Flicker	*Colaptes auratus*	terr	resident	IV	1
Ash-throated Flycatcher	*Myiarchus cinerascens*	air	resident	DS,IV	2
Say's Phoebe	*Sayornis saya*	air	resident	GN	2
Black Phoebe	*Sayornis nigricollis*	air	resident	DS	1
Loggerhead shrike	*Lanius ludovicianus*	terr	resident	DS,IV	5
Warbling Vireo	*Vireo gilvus*	terr	migrant	IV	1
Common Raven	*Corvus corax*	terr	resident	DS,IV	3
Horned Lark	*Eremophila alpestris*	terr	migrant	DS	1
Tree Swallow	*Tachycineta bicolor*	air	migrant	DS,GN,IV	5

SPECIES		**Zone**	**Residency**	**Sites**	**MNI**
Cliff Swallow	*Petrochelidon pyrrhonota*	air	resident	GN	5
No. Rough-winged Swallow	*Stelgidopteryx serripennis*	air	migrant	IV	2
Verdin	*Auriparus flaviceps*	terr	resident	IV	3
Blue-gray Gnatcatcher	*Polioptila caerulea*	terr	resident	IV	1
Northern Mockingbird	*Mimus polyglottos*	terr	resident	IV	1
American Pipit	*Anthus rubescens*	terr	migrant	IV	4
Orange-crowned Warbler	*Oreothlypis celata*	terr	migrant	IV	1
Lucy's Warbler	*Oreothlypis luciae*	terr	resident	IV	1
Yellow-rumped Warbler	*Setophaga coronata*	air	migrant	IV	14
Black-throated Gray Warbler	*Setophaga nigrescens*	terr	migrant	IV	1
Hermit Warbler	*Setophaga occidentalis*	terr	migrant	GN	1
Townsend's warbler	*Setophaga townsendi*	terr	migrant	DS,IV	4
Yellow Warbler	*Setophaga petechia*	terr	migrant	IV	1
Black-and-white Warbler	*Mniotilta varia*	terr	migrant	IV	1
MacGillivray's Warbler	*Oporornis tolmei*	terr	migrant	IV	1
Wilson's Warbler	*Cardellina pusilla*	terr	migrant	DS,IV	4
Common Yellowthroat	*Geothlypis trichas*	terr	migrant	DS	1
Western Tanager	*Piranga ludoviciana*	terr	migrant	DS,IV	4
Black-headed Grosbeak	*Pheucticus melanocephalus*	terr	migrant	DS,GN	2
Lazuli Bunting	*Passerina caerulea*	terr	migrant	IV	1
Blue Grosbeak	*Passerina caerulea*	terr	resident	IV	1
Green-tailed Towhee	*Pipilo chlorurus*	terr	migrant	IV	1
Brewer's Sparrow	*Spizella breweri*	terr	resident	IV	3
Chipping Sparrow	*Spizella passerina*	terr	resident	GN,IV	4
Black-throated Sparrow	*Amphispiza bilineata*	terr	resident	DS,IV	4
Savannah Sparrow	*Passerculus sandwichensis*	terr	migrant	DS,IV	3
White-crowned Sparrow	*Zonotrichia leucophrys*	terr	migrant	IV	6
Pine Siskin	*Spinus pinus*	terr	migrant	IV	1
House Finch	*Carpodacus mexicanus*	terr	resident	IV	13
Great-tailed Grackle	*Quiscalus mexicanus*	terr	resident	DS,IV	5
Brown-headed Cowbird	*Molothrus ater*	terr	resident	DS,GN,IV	8
Yellow-headed Blackbird	*Xanthocephalus xanthocephalus*	terr	migrant	DS	1
Bullock's Oriole	*Icterus bullockii*	terr	resident	GN	2

Species recovered from one site: 47
two sites: 18
three sites: 5

Appendix 2. Species with solar flux burns

Common Name	Scientific name	
Yellow-rumped warbler	*Setophaga coronata*	12
House finch	*Carpodacus mexicanus*	10
Chipping sparrow	*Spizella passerina*	2
Unidentified warbler	*Parulidae*	2
Verdin	*Auriparus flaviceps*	2
Great-tailed grackle	*Quiscalus mexicanus*	2
Lucy’s warbler	*Oreothlypis luciae*	1
Wilson's warbler	*Cardellina pusilla*	1
MacGillivray's warbler	*Oporornis tolmei*	1
Black-throated gray warbler	*Setophaga nigrescens*	1
Townsend's warbler	*Setophaga townsendi*	1
Orange-crowned warbler	*Oreothlypis celata*	1
Blue-gray gnatcatcher	*Polioptila caerulea*	1
Unidentified swallow	*Hirundinidae*	1
Northern rough-winged swallow	*Stelgidopteryx serripennis*	1
Warbling vireo	*Vireo gilvus*	1
Unidentified hummingbird	*Selasphorus sp.*	1
Unidentified passerine	Passeriformes	1
Unidentified finch	*Carpodacus sp.*	1
Lazuli bunting	*Passerina caerulea*	1
Unidentified sparrow	*Spizella species*	1
Unidentified blackbird	*Icteridae*	1
Peregrine falcon	*Falco peregrinus*	1

GREGORY P. SCHNECK
VICE PRESIDENT

9. TYPE OF PERMIT
MIGRATORY BIRD SPECIAL PURPOSE UTILITY PERMIT - SOLAR

10. LOCATION WHERE AUTHORIZED ACTIVITY MAY BE CONDUCTED

Records location: 1000 Draker Drive, Blythe, CA 92225, Riverside County, CA
Collection location: 1000 Draker Drive, Blythe, CA 92225, Riverside County, CA
Freezer location: 1000 Draker Drive, Blythe, CA 92225, Riverside County, CA

11. CONDITIONS AND AUTHORIZATIONS:

A. GENERAL CONDITIONS SET OUT IN SUBPART D OF 50 CFR 13, AND SPECIFIC CONDITIONS CONTAINED IN FEDERAL REGULATIONS CITED IN BLOCK #2 ABOVE, ARE HEREBY MADE A PART OF THIS PERMIT. ALL ACTIVITIES AUTHORIZED HEREIN MUST BE CARRIED OUT IN ACCORD WITH AND FOR THE PURPOSES DESCRIBED IN THE APPLICATION SUBMITTED. CONTINUED VALIDITY, OR RENEWAL, OF THIS PERMIT IS SUBJECT TO COMPLETE AND TIMELY COMPLIANCE WITH ALL APPLICABLE CONDITIONS, INCLUDING THE FILING OF ALL REQUIRED INFORMATION AND REPORTS.

B. THE VALIDITY OF THIS PERMIT IS ALSO CONDITIONED UPON STRICT OBSERVANCE OF ALL APPLICABLE FOREIGN, STATE, LOCAL, TRIBAL, OR OTHER FEDERAL LAW.

C. VALID FOR USE BY PERMITTEE NAMED ABOVE.

This permit does not supersede any State Requirements. You are responsible for ensuring that you are in compliance with all State laws, including but not limited to California Fish and Game Code 3511 (fully protected species) 3503.5 and 3513. For additional information on State requirements please contact: California Department of Fish and Wildlife, Magdalena Rodriguez, 909-945-3294.

D. **Possession and transport.**

1) You and subpermittees are authorized to handle, collect, transport and temporarily possess carcasses and partial remains of birds protected under the Migratory Bird Treaty Act, **except Bald Eagles and Golden Eagles (Eagles)** and species listed as **Threatened or Endangered** under the U.S Endangered Species Act (see 50 CFR § 17.11), found at the location/property specified in Block 10 for monitoring bird mortality associated with operation of the solar facility. To accurately determine species fatality rates, the monitoring study must include standardized carcass searches, searcher efficiency trials, and carcass removal by scavenger trials. For **Eagles and federally listed Threatened or Endangered Species** you must call a U.S. Fish and Wildlife Service (Service), Office of Law Enforcement (OLE) special agent for instructions and approval before collecting or moving the carcass or its parts. It may be necessary to preserve the carcass or its parts onsite until an agent or other Service or State representative arrives to collect it. **Your OLE point-of-contact is Resident Agent Erin Dean, email: erin_dean@fws.gov ,**

☒ ADDITIONAL CONDITIONS AND AUTHORIZATIONS ALSO APPLY

12. REPORTING REQUIREMENTS

ANNUAL REPORT DUE: 01/31
You must submit an annual report to your Regional Migratory Bird Permit Office each year, even if you had no activity. Form: www.fws.gov/forms/3-202-17.pdf.

ISSUED BY

TITLE
MIGRATORY BIRD PERMIT SPECIALIST

DATE
03/25/2015

phone: 310-328-1516

2) Except for take caused by your infrastructure and operations, you may not collect or disturb and must immediately report to OLE any dead migratory birds that appear to have been poisoned, shot, or otherwise killed or injured as the result of potential criminal activity.

3) As a condition of this permit, you are required to complete an avian mortality monitoring plan for the solar facility as part of a Bird and Bat Conservation Strategy (BBCS, previously referred to as Avian and Bat Protection Plans) prior to the expiration of this permit. The BBCS should include measures to avoid and minimize take of migratory birds during construction, as appropriate, and operation of the solar facility, as well as adaptive management actions and a monitoring plan to quantify avian mortality and evaluate the effectiveness of any avoidance and minimization measures. Upon determination by the Service that the BBCS and monitoring plan are acceptable, you will need to complete a new application form for a three-year operational Special Purpose - Utility permit (Form 3-200-81).

E. **Data Collection.**

Mortality data should be compiled in the attached Excel spreadsheet and submitted to the Service on a monthly basis until directed differently by permit official. It includes but is not limited to the collection of the following information:

1) All relevant and applicable data associated with each carcass or part collection, or injured bird, should be recorded, including the information below. Required data are designated with an asterisk (*).

   a) discovery date*
   b) collection date*
   c) species*
   d) sex and age (juvenile/adult), if known
   e) condition of bird (alive or dead) *
   f) condition of carcass (entire, partial, scavenged)*
   g) description of carcass (e.g., intact, feather spot, headless, wing sheared, blood in mouth, entanglement)*
   h) interval since last search*
   i) observer*
   j) search method used, including opportunistic discovery of carcasses*
   k) weather conditions at likely time of death, if known*
   l) identifying information for the infrastructure element, e.g. solar panel, evaporation pond, fencing, building
   m) the GPS coordinates in decimal degrees for the location where carcass/part found*
   n) ground distance of carcass from pole, line, panel, or other structure (e.g pond or building)
   o) azimuth of carcass from solar panel or infrastructure (including GPS coordinates in decimal degrees), if known
   p) apparent cause of mortality/injury (collision, electrocution, drowned, other) *
   q) estimated date of mortality or estimate of time since death (e.g., <1 day, 1 day, 2-3 days)*
   r) habitat surrounding carcass (*e.g.*, desert, grassland, rural, urban, cropland, bare ground, tall grass)
   s) information on carcass or injured bird disposition*
   t) any special notes or additional information
   u)

2) All carcasses and partial remains that are collected should be digitally photographed, bagged, and labeled with the following information:

   a) date collected
   b) a unique specimen number
   c) the information listed in E(1)(l and m) above
   d) facility name

F. **Injured birds.** Injured migratory birds, including **eagles and federally listed threatened or endangered species,** must be transferred to a federally permitted migratory bird rehabilitator or a licensed veterinarian for care. Rehabilitation and/or veterinary costs are the utility's responsibility. See condition H for reporting instructions.

G. **Take and collection of live, non-injured migratory birds, eggs, or nests is not authorized by this permit.** In addition, this permit does not authorize the take, capture, harassment or disturbance of **eagles or federally listed endangered or threatened species** (see 50 CFR 17.11).

H. **Reporting.**

1) You must report bird injuries and deaths in accordance with the time frames specified below (a-c).

a. You must submit a written report of avian mortality and injury **monthly** to OLE, the Regional Migratory Bird Permit Office (RMBPO), the Ecological Service's Field Office (Field Office) and California Department of Fish and Wildlife (CDFW). Your report must include as much of the data listed in condition E above that is available for each incident. In addition, we request that you voluntarily report bat injury and mortality information.

- OLE SA: Your OLE point-of-contact is Resident Agent Erin Dean, (erin_dean@fws.gov , phone 310-328-1516)
- RMBPO: Heather Beeler (heather_beeler@fws.gov, phone: 916-414-6651)
- Field Office- Palm Springs: Pete Sorensen (pete_Sorensen@fws.gov, phone: 760-431-9440 x293)
- CDFW: Email to Armand Gonzales (Armand.Gonzales@wildlife.ca.gov) and Magdalena Rodriguez, Magdalena.Rodriguez@wildlife.ca.gov)

b. *Eagles and T/E Species*: In addition to the monthly reports, you must report any **bald eagle or golden eagle or threatened or endangered species** found dead or injured to the OLE and each contact listed in H (1)(a) immediately if possible, but no later than **24 hours after discovery.** Your report must include as much of the information from condition E that is available for each incident. A written mortality or injury report specific to the eagle or listed species must be submitted to all contacts listed in condition H(1)(a), to include the data in condition E, no later than **one week (7 days)** from the date of discovery of the carcass.

A list of Threatened and Endangered species by State may be found in the Service's Threatened and Endangered Species System (TESS) database at: <http://www.fws.gov/endangered>.

c. *Significant Mortality Events*: In the event that you discover 6 or more migratory birds that have been injured or killed within a 24 hour period, you must report the event to RMBPO and the Field Office listed in condition H(1)(a) above immediately if possible, but no later than the **next business day**. This summary must list the number of events by species. Within 14 days of carcass/injury discovery, a written mortality or injury report specific to the incident must be submitted to your FWS contacts, and should include as much of the data in E above as possible. This reporting requirement is intended to inform the Service of events or other variables that may have contributed to the mortality event.

2) *Annual Report:* You must submit a cumulative annual report of all activities authorized under this permit to your migratory bird permit issuing office by **January 31** following each calendar year in which the permit is in effect, including:

a. All dead and injured birds, including **Eagles and T/E Species**, discovered or collected, your report must include at a minimum the information required in Condition F.

3) *Submitting Reports:* This permit has an electronic annual report. The spreadsheet report form can be downloaded from: http://www.fws.gov/forms/3-202-17.xlsm. Instructions are available on Tab 1 of the spreadsheet. Complete Tab 2, and if appropriate Tab 3. Email your monthly reports as described above in condition 1(a-c) above. Email your Annual Report by January 31 to **|Heather_Beeler@fws.gov|** **AND** **MigBirdReports@fws.gov** with the subject line "SPUT Solar - McCoy Solar Project|". You may submit an Excel spreadsheet from your own database, provided all of the "required" information is included in exact format.

I. Disposition of Carcasses and Parts.

1) In accordance with Condition D(1) above, the Service will advise you on disposition of **Eagles and federally listed Threatened or Endangered Species** specimens. The special agent will advise if they will recover an eagle carcass or if you need to ship the carcass to the Service. With PRIOR written authorization from an OLE special agent, you may contact the U.S. Fish and Wildlife Service, National Eagle and Wildlife Property Repository (NER) at (303) 287-2110 for shipping instructions. The written authorization from the special agent must accompany the Eagle if it is shipped to the NER. Disposition must be reported in your annual report to your migratory bird permit issuing office.

2) Migratory birds, other than Eagles and federally listed Threatened or Endangered Species, may be used for searcher efficiency trials and carcass removal trials AFTER a mortality report has been submitted to Regional Migratory Bird Permit Office per condition H(1)(e) documenting their death, all data collected in condition E(2), and the unique specimen number assigned to that carcass in condition E(3) above.

3) Unless otherwise specified in this permit, **Migratory Bird carcasses** and parts (**other than Eagles and federally listed Threatened or Endangered Species**) collected during the calendar year (ending Dec 31) that have been documented in your records must be stored in the freezer at the facilities at the location specified in Block 10. **AFTER** a mortality report has been submitted to Regional Migratory Bird Permit Office per condition H(1)(e) documenting their death, all data collected in condition E(2), and the unique specimen number assigned to that carcass in condition E(3), carcasses maybe:

(a) used for searcher efficiency and scavenger removal trials; provided carcasses used in trials have been reported to the Service prior to use,

(b) turned over to the State wildlife agency for official purposes, or,

(c) donated to a public scientific or educational institution or to an individual or entity authorized by Federal permit to acquire and possess migratory bird specimens.

After all permit requirements have been met, carcasses and parts (**except Eagles and federally listed Threatened or Endangered species**) that you do not transfer to another authorized party must be disposed of by burial or incineration.

J. **Construction Only Authorization.** This permit authorizes you and your subpermittees to pick up Migratory Bird carcasses and parts (**other than Eagles and federally listed Threatened or Endangered Species**) during project construction only as required for compliance with your Raven Management Plan.

K. **Renewal**. A one year extension, of this construction phase permit maybe granted with a written request and consensus from the U.S. Fish and Wildlife Service's Palm Springs Ecological Service's Field Office. A new permit application is required to obtain authorization to handle migratory bird carcasses during the operational phase of the project once a mortality monitoring plan is approved. Upon determination by the Service that the BBCS and monitoring plan are acceptable, you will need to complete a new application form for a three-year operational Special Purpose - Utility permit (Form 3-200-81).

L. **Subpermittees.** Any person who is employed by or under contract to the permittee for the activities specified in this permit, or is otherwise designated as a subpermittee in writing by the permittee may exercise the authority of this permit.

M. **Standard Conditions.** You and any subpermittees must comply with the attached **Standard Conditions for Migratory Bird Special Purpose Utility Salvage Permits. These standard conditions are a continuation of your permit conditions and must remain with your permit.**

This permit does not supersede any State Requirements. You are responsible for ensuring that you are in compliance with all State laws, including but not limited to California Fish and Game Code 3511 (fully protected species) 3503.5 and 3513. For additional information on State requirements please contact: California Department of Fish and Wildlife, Deborah Hawk, 760-872-1126.

This permit does not, nor shall it be construed to, authorize lethal take or injury of migratory birds or limit or preclude the U.S. Fish and Wildlife Service from exercising its authority under any law, statute, or regulation, or from taking enforcement action against any individual, company, or agency. This permit is not intended to relieve any individual, company, or agency of its obligations to comply with any applicable Federal, State, Tribal, or local law, statute, or regulation.

This permit may be amended at any time in response to changes in national guidance or take reported.

Avian and Wildlife Reporting Form

***** All Fields Must Be Filled Out. Do Not Leave Any Field Blank. *****

INCIDENT DETAILS

Observation Made During (circle one):

Evaporation Pond Monitoring / Scheduled Mortality Survey / [✓ Incidental]

Date: 6/10/2013 Observer: Ron Walker

Type of Incident (circle one): [✓ Injury] / Fatality / Nest

Condition (circle one): Intact Carcass / Dismembered Carcass / Feathers Only

Age of Remains (circle one): 1-5 (fluid filled eyes) / 6-30 (maggots) / 30+ (bones)

Photo No.

Carcass Condition Details, Behavior of Injured Animal or Nest Details: Injured brown pelican found in unit 2 in power block area under HTF overhead pipes, above power block access road. Pelican appeared to be suffering from heat stress. Pelican transported to wildlife rehabilitation center in Blythe, CA. It was reported later that the pelican recovered and was released uninjured.

LOCATION

DATUM: UTM Z11 NAD83 (m) UTM N: 3726434 UTM E: 686893

Found Near (circle one):

Solar Trough / Evaporation Pond / Road / Power Line / [✓ Other (explain below)]

Location Details: Unit 2, west side of power block, under HTF pipe overhead crossing

IDENTIFICATION

[✓ Bird] / Bat / Unknown / Other (circle one)

Species (if unknown, write 'unknown'): Brown Pelican

Color/Markings: Brown, light underbelly

Sex (circle one): Male / Female / [✓ Unknown] Age (circle one): Adult / Juvenile / [✓ Unknown]

Is Animal Tagged? (circle one): Yes / [✓ No]

Identification Remarks: N/A

ENVIRONMENTAL CONDITION

Weather (circle one): [✓ Clear] / Fog / Cloudy / Rain

Approx. Temperature (circle one): [✓ °F] / °C: 109

Wind (circle one): Calm / [✓ Gusty] / Storm / Violent Storm

Habitat (circle all that apply):

Bare Ground / Creosote Bush Scrub / Sand Dunes

Sand Drifts over Playa / Ephemeral Wash / Desert Pavement

NOTIFICATION

Who was notified, and When? Designated biologist on 6/10/2013 4:30:00 PM

Actions Taken (e.g., left in place, taken to rehab): Brown pelican picked up and transported to wildlife rehabilitation center in Blythe CA

COMMENTS:

Injured brown pelican found in unit 2 in power block area under HTF overhead pipes, above power block access road. Pelican appeared to be suffering from heat stress. Pelican transported to wildlife rehabilitation center in Blythe, CA. It was reported later that the pelican recovered and was released uninjured.

* Turn in completed form and incident photos to the on-site Environmental Manager.

* Report any incidental observations of dead birds or other wildlife at the evaporation ponds to the Designated Biologist within one day of the detection of the carcass.

* Report any nests immediately to the on-site Environmental Manager.

Subject: 2015 Annual Report for the Blythe Solar Power Project (BSPP) Scientific Collecting Permit (SCP) SC-002067
Date: February 16, 2016
cc: Dave Hochart, Dudek
Bobby Hall, NextEra Energy Resources
Adrienne Charbonneau, NextEra Energy Resources
Att: Attachment A – Avian Mortality Monitoring Spreadsheet / Special Purpose Utility Excel Data Sheet

---

Introduction

This memorandum provides a summary of avian carcasses collected and documented under Scientific Collecting Permit (SCP) No. SC-002067 at the Blythe Solar Power Project (BSPP) from October 14, 2015 (date the permit was issued) through the end of the reporting year (December 31, 2015). This report serves as the "Annual Report" required in accordance with section "10. Reporting" of SCP Permit No. SC-002067.

In addition, it should be noted that in accordance with section "10. Reporting" of SC-002067, it is acceptable to present a summary of avian carcasses collected during this reporting period through the use of the Service's excel file, which is being used in accordance with federal permit MB5843B-0:

> "A current version of the Service's "Avian Mortality Monitoring Spreadsheet/Special Purpose Utility Excel Data Sheet" (Excel file) shall be used to tabulate the salvaged and injured birds, quarterly and annually, unless otherwise instructed by the Department contact. The spreadsheet shall be submitted electronically along with the quarterly and annual reports."

Summary

During the reporting period indicated above (October 14, 2015 through December 31, 2015), three (3) avian carcasses were collected, documented, and placed in an on-site freezer, in accordance with federal permit MB5843B-0. Details about the carcasses collected during this reporting period are included in **Attachment A.**

Adjusted Annual Mortality Estimates

In accordance with section "10. Reporting" of SC-0022067, annual reports should include:

> "adjusted annual mortality estimates for all birds (including additional mortality estimates for small birds, large birds, and raptors) whose death appears related to the operation of the Blythe Solar Power Project."

It is Dudek's understanding that since no avian mortalities during this reporting period appeared to be the result of project-related activities, it is not feasible to adequately estimate the number of mortalities estimated for the next reporting period (2016). SC-002067 requires another annual report to be submitted in January 2017, and at that time, after a full year of data is collected under this SCP permit, an annual mortality estimate will be made.

Please feel free to contact me at bortega@dudek.com or 760.479.4254 if you have any questions regarding the contents of this memorandum.

Brock Ortega
Project Biologist

Re:	Imperial Solar Energy Center (ISEC) South – Burrowing Owl (BUOW) Mortality Retraction	

On November 22, 2011 UltraSystems issued a memo that reported a burrowing owl mortality for the Imperial Solar Energy Center – South project.

This memo serves to retract that statement, since only burrowing owl feathers were found on site, and no carcass was discovered (GPS coordinates of feathers: +32.67201, –15.65852). There is no confirmation that a mortality occurred.

Should you have any questions, please contact me at (949) 788-4900.

Post-construction Avian Mortality Monitoring Report
Campo Verde Solar Project

Year 2 Annual Report (October 2014 – September 2015)

Prepared By:

Heritage Environmental Consultants, LLC

December 2015

Table of Contents

1 Introduction

The Campo Verde Solar Project is a solar photovoltaic (PV) energy generating facility (Solar Energy Facility) and an associated electrical transmission line (Gen-Tie Line) in southern Imperial County, California. The solar project is located on private lands and the gen-tie line is located on private and federal lands managed by the Bureau of Land Management (BLM). These are referred to collectively as the "project."

A Bird and Bat Conservation Strategy (BBCS) was prepared that addresses activities potentially occurring during construction and operation of the project (Heritage 2013). The BBCS was reviewed and approved by the U.S. Fish and Wildlife Service (FWS), California Department of Fish and Wildlife (CDFW), and BLM. The purpose of the Campo Verde BBCS was to develop and implement a program to identify and avoid risks to avian and bat species that could result from construction and operation of the project. The goal of this BBCS was to implement a series of best practices, in order to construct and operate the project to avoid or reduce risk to birds, bats and their habitats.

The post-construction avian mortality monitoring program was set up to comply with the methodology prescribed in the BBCS (Heritage 2013). The methodology is described in Section 6.1 of the BBCS and was approved by the FWS and CDFW. Quarterly reports documenting results of the monitoring program were required for the first year of the program, and annually thereafter. Monitoring began in October 2013 just after completion of construction. This report is the second annual report documenting the results of monitoring from October 2014 to September 2015.

1.1 Project Description

The general location of the project is approximately 7 miles southwest of the city of El Centro, Imperial County, California (**Figure 1**). The project is south of I-8, west of Drew Road, and northeast and south of the Westside Main Canal. The Project consists of two component parts: (i) the Solar Energy Facility, and (ii) an approximately 0.9-mile, 230-kilovolt (kV) aboveground, electrical gen-tie line and associated facilities that electrically connect the Solar Energy Facility on private land with the Imperial Valley Substation (IV Substation) located on federal land managed by the BLM.

The Solar Energy Facility is approximately 1,443 acres in size and uses First Solar PV modules that are generally non-reflective and convert sunlight into direct current (DC) electricity. The DC output of multiple rows of PV modules is collected through one or more combiner boxes and directed to an inverter that converts the DC electricity to alternating current (AC) electricity. From the inverter, the generated energy flows to a transformer where it is stepped up to distribution level voltage (approximately 34.5 kV). Multiple transformers are connected in parallel via 34.5 kV lines to the project substation, where the power is stepped up to 230 kV. This substation is located at the southern end of the Solar Energy Facility near Liebert Road. The Gen-Tie Line connects the project substation to the Imperial Valley Substation approximately 0.9 miles to the south.

The Gen-Tie Line uses double-circuit tubular steel monopole structures. Tower structure heights range from 100 to 135 feet. One side of the double-circuit structures currently supports three two- bundle conductors and one shield wire. Typical overall structure widths are approximately 20 feet.

Project Facilities

2 Methods

Monitoring of the project was performed in order to document and report avian mortalities and identify areas of concern by tracking both the specific locations where mortalities occur as well as the extent of such mortalities. The monitoring program for the project is based on the FWS guidance entitled "Monitoring Migratory Bird Take at Solar Power Facilities: An Experimental Approach" (FWS 2012) with modifications, and was approved by FWS.

2.1 Transect Sampling

Sampling transects were established for both the gen-tie line and solar field. For each kilometer of Gen-Tie Line, 300-meter transects were randomly established along the Gen-Tie Line allowing for approximately 30-percent of the Gen-Tie Line to be sampled. Transects were positioned along the centerline of the Gen-Tie Line. For the Campo Verde Solar Energy Facility, transects were also positioned to result in approximately 30-percent coverage of the site with no less than eight transects placed within the solar field itself. Transect selection was systematic randomized. The entire perimeter of the panel arrays was also surveyed during each survey period in addition to the interior transects.

Transects were surveyed for 7 consecutive days each month and each transect was surveyed once daily. Because of the large number of transects, sampling periods were 14-days; the first half of transects were walked for 7-day period and the second half for another 7-day period. One qualified observer walked along the pre-determined transects searching for bird/bat carcasses. When a carcass was observed, a GPS location was recorded at the carcass, the species was identified, the perpendicular distance from the transect to the carcass was measured, and information regarding carcass condition, per FWS (2012), was recorded using paper datasheets. Once data were collected at a carcass, the observer returned to the pre-determined transect and continued with the survey.

The original protocol stated that each carcass would be marked uniquely and inconspicuously with tape and permanent marker to assess "recapture" rates. The federal special purpose utility permit (SPUT) was received in September of 2014 while the state scientific collection permit (SCP) enabling surveyors to handle carcasses was issued in November of 2014. The scavenger removal trials and searcher efficiency trials commenced during the Q1 2015 monitoring period.

2.2 Analysis

Program DISTANCE was used to determine the most effective transect width to search for carcasses. Distance models examined a variety of detection functions and used Aikake's Information Criterion (AIC)[1] for model selection. DISTANCE modeling was run using both a 5% upper truncation to remove outliers and without any truncation. Specific model components are discussed in **Section 3.2**.

Two annual project mortality estimates were calculated: one that incorporated statistical corrections for searcher bias and scavenger removal and one that did not. The mortality estimate that did not include detection probability corrections is presented to facilitate comparisons to past avian mortality reports for the Campo Verde Solar Project, which did not include detection probability estimates.

Uncorrected project mortality estimates rely on measuring a daily mortality rate that can be used as the basis for all mortality estimates. To calculate the corrected project mortality estimate, we did not count all mortalities observed during day 1 of the 7-day search period under the assumption that those mortalities represent "bleed through" from the period prior to 24 hours preceding the first search. To accurately generate a rate, all mortalities used for this analysis need to have occurred within the 24 hours preceding discovery. Mortalities observed during the subsequent 6 days were then up-corrected to adjust for time

---

[1] AIC measures the relative quality of a given model by assessing both the model's complexity as well as the model goodness-of-fit to the observed data. Lower AIC values indicate higher quality models. Typically AIC values are compared among several possible models to select the "best" model or models.

not searched (since the search period captured 6 out of 28, 30 or 31 days each month), producing a time-corrected mortality estimate for each month.

Scavenger removal trials were conducted in May and June of 2015. During each trial, 10 carcasses were placed along a set of transects in randomly selected locations. Carcasses were checked daily for seven days with the status of each carcass recorded during each check. Results from these trials were used to calculate daily persistence probability using an exponential model which assumes constant persistence probabilities over time (Klien and Moerschberber 2003; Korner-Nievergelt et al. 2011).

Searcher efficiency trials began in May of 2015 and were conducted on all observers each month. Carcasses were placed along a randomly selected transect without the knowledge of the observer being tested. Between five and ten carcasses were used during each trial. A searcher efficiency rate was calculated for each trial by determining the proportion of available carcasses that were successfully detected by the observer. Carcasses that were scavenged prior to the transect being walked were eliminated from analysis. The average searcher efficiency rate was calculated by calculating the mean of all trials and 95% upper and lower confidence intervals were also calculated.

Overall detection probability was calculated by combining the results of the searcher efficiency trials and the scavenger removal trials using the methods described by Korner-Nievergelt et al. (2011). This method allows for the calculation of a single detection probability for the project and assumes constancy for this value over time. This detection probability is then used to calculate a posterior distribution estimate of the number of fatalities. We used the median of this distribution as the corrected mortality estimate representing the estimated true number of carcasses available within the search area during days 2-7 of the surveys. This estimate was reported as well as the upper and lower 95% confidence interval for these estimates. We also used the time and area correction methods described above to generate a full-project annual mortality estimate that accounts for searcher efficiency and scavenger removal.

Because taxonomic analyses do not use a rate, but are instead only concerned with the overall breakdown in mortalities, these analyses used all recorded mortality data, including those mortalities observed during day 1 of the 7-day search period. The use of these data from day one assumes that there is not persistence bias for different taxa of birds.

3 Results

3.1 Overall Mortalities Observed

A total of 126 avian mortalities were recorded during the second year of surveys. Twenty-three (23) of these observed mortalities were recorded as "feather spots". **Table 1** provides a breakdown of mortalities by sampling period.

The inclusion of feather spots as observed mortalities is based on standard mortality monitoring protocols, which were largely developed for the wind energy industry. At wind energy facilities, the speed of the spinning blades can result in mortalities that leave very little detectible carcass behind, including only feather spots. Inclusion of feather spots as recorded mortalities at these facilities was intended to conservatively include mortalities caused by blade strikes that might otherwise go unrecorded. Potential bias resulting from the inclusion of feather spots in mortality data can arise from feather spots meeting the definition of a mortality but not actually resulting from an avian mortality. This bias can lead to overestimates of mortality rates and is problematic in situations where feathers are commonly deposited in non-mortality related events but get included as incidents of avian morality (e.g. in and around common roost or perch sites, near active nests, etc.). Feather spots may also be caused by predation or attempted-predation events within a survey area. Based on the large proportion of feather spots observed during early surveys at this site, observers used greater discretion when encountering feather spots to help mitigate this bias. Feather spots that strongly indicated a deposition of feathers that was unrelated to an avian mortality or injury were excluded from the database; in instances where observers were uncertain, the feathers spots were recorded as mortalities in order to be conservative. All of the following analyses present results that both include and exclude feather spots to present the full range of possible mortalities.

Table 1 – Observed Mortalities by Sampling Period

Mort. Type	**Q4 2014**			**Q1 2015**			**Q2 2015**			**Q3 2015**			***Total***

Total Mort.	16	7	10	11	9	4	10	5	4	8	15	32	*131*

A single Mexican free-tailed bat (*Tadarida brasiliensis*) carcass was found on July 10 underneath a solar panel. Due to differences in detection probabilities and collision risk between mammals and birds, this mortality is not included in mortality rate calculations or taxonomic compositions analyses. However, this mortality is included in the DISTANCE analysis, since effective transect width should account for observer detection of mammals despite the apparent infrequency with which they are found onsite (this mortality represents only the second bat detected during the 2 years of surveys).

3.2 Effective Transect Width

DISTANCE analyses were performed using the data pooled across the twelve-month sampling period. Analyses were run that both included and excluded feather spots as were analyses that both truncated the upper 5% of the data and left the data untruncated. **Tables 2-5** present the results of the DISTANCE analyses run. It is important to note that none of the models fit the data well. Multiple errors occurred due to parameters being constrained to obtain monotonicity and some parameters exhibiting high correlation. Overall sample sizes were very small relative to the area sampled during the first year of surveys, which is likely the primary factor limiting the reliability of the DISTANCE analysis.

The a priori estimate of effective transect width was approximately 7.5 meters (this represents the width of two panel rows measured from the bottom of the panel immediately north of the designated transects to the bottom of the second panel to the south of the transect). Generally, the most likely models were consistent with or exceeded that assumption. Sample sizes were relatively small for all models run this year and model results should be used with a high degree of caution (e.g. note that modeled density was rounded to 0.00 or 0.001 for all model definitions as a results of low sample sizes and unreliable model results).

3.3 Project Mortality Estimate

3.3.1 No Detection Probability Correction

Results from surveys conducted each month were used to generate discrete mortality estimates for each month surveyed that did not include any correction for detection probability. Monthly and overall project mortality estimates only used data from search days 2-7 (see **Section 2.2**). Monthly mortality estimates were used in order to detect seasonal variations in mortality rates. Also, data are presented to reflect estimates with and without feather spots, as discussed earlier. For the remainder of this section, mortality values are presented as "number of mortalities excluding feather spots"/"number of mortalities inclusive of feather spots".

While results of the DISTANCE analyses were less than conclusive, they were at least consistent with the a priori assumption of a minimum 7.5-meter effective transect width. Transect layout, in consideration of this assumed effective transect width, was designed to sample 30% of the overall PV array area. The time-corrected mortality estimates for each month were again up-corrected to account for the area not surveyed. Mortality estimates were rounded to the nearest whole number. **Table 6** summarizes the corrected mortality estimates by month. **Figure 2** shows the trend of mortality estimates over the course of the year's surveys.

Table 6 – Uncorrected project mortality by month

	Q4 2014			Q1 2015			Q2 2015			Q3 2015			Annual Totals

*Trendlines are 4th order polynomial regressions.

3.3.2 With Detection Probability Correction

Overall searcher efficiency, beginning in May 2015, was calculated at over 93%. Average carcass persistence time in scavenger removal trials was 5.7 days. The overall detection probability for the project was calculated as approximately 0.73.

Table 7 presents the detection probability corrected results for each survey period along with upper and lower 95% confidence interval values. **Table 8** presents the time and area corrected monthly estimates. **Figure 3** shows the trend of corrected mortality estimates over the course of the year's surveys. The overall project mortality from October 2014 to September 2015 was 2,447/3,073 avian mortalities.

3.4 Taxonomic Composition of Observed Mortalities

The following analyses use all observed mortalities including those detected on search day 1 since the taxonomic composition is not a rate-dependent analysis (see **Section 2.2**).

Table 9 – Raw Mortalities by Month (includes data from all search days)

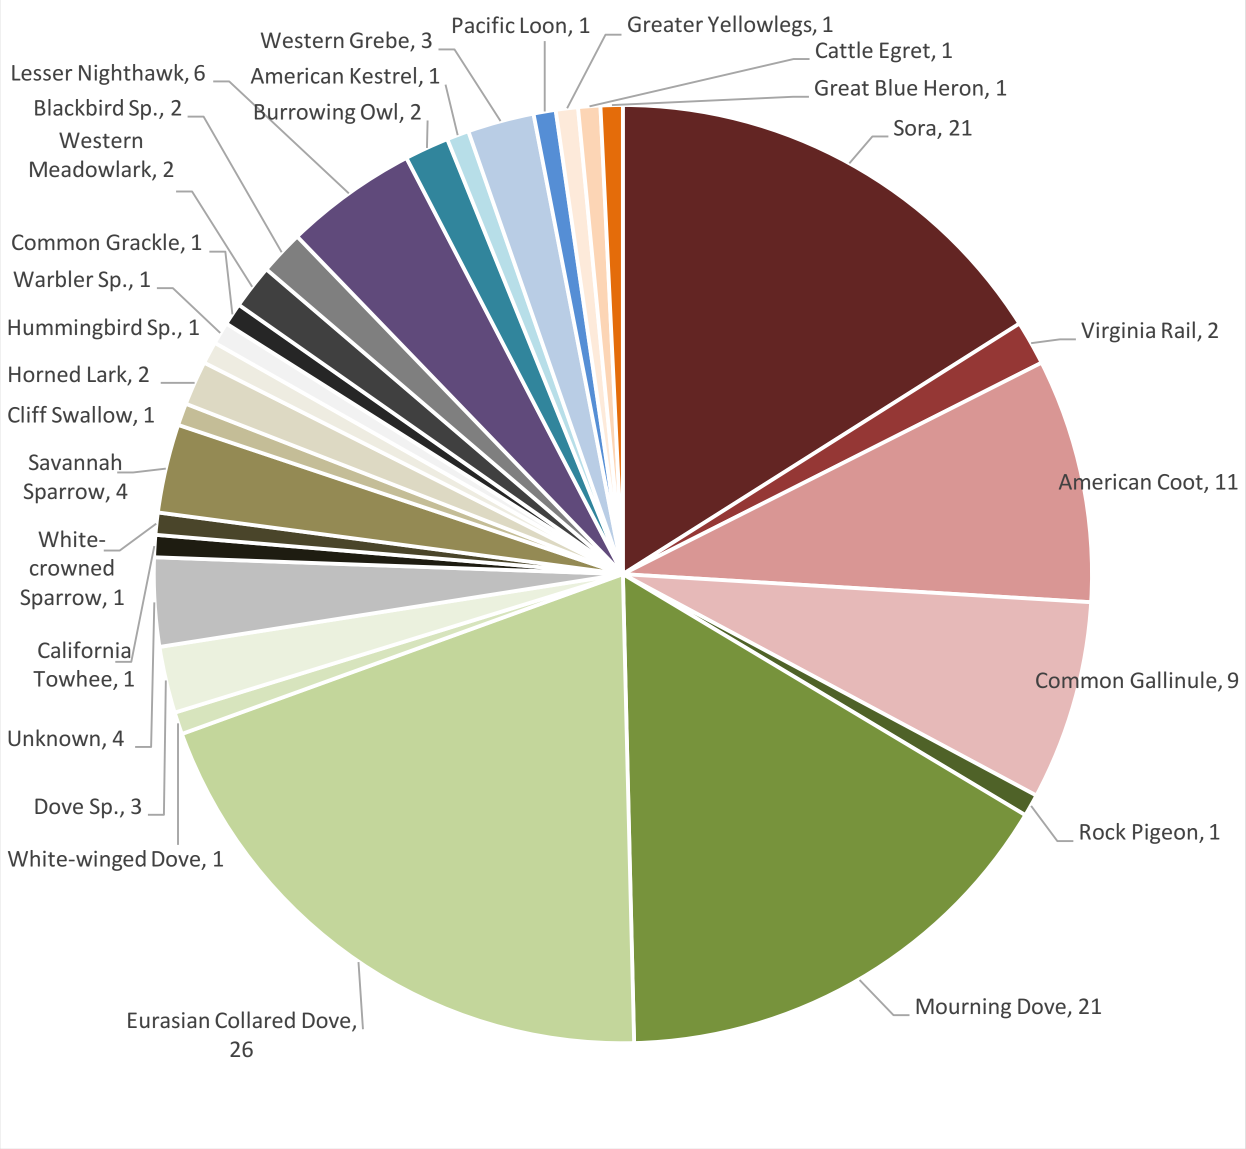
3.4.1 Mortalities Including Feather Spots

A total of 131 mortalities were observed during the first year of surveys when feather spots were included in the data set. Eleven (1) of these mortalities (8%) could not be identified to species. Of the 120 carcasses that could be identified to species, the most commonly observed species were Eurasian Collared Dove (*Streptopelia decaocto*; 26 mortalities; 22% of mortalities identified to species level), Mourning Dove (*Zenaida macroura*; 21 mortalities; 18% of mortalities identified to species level), and Sora; (*Porzana carolina*; 21 mortalities; 18% of mortalities identified to species level). **Figure 4** presents the breakdown of observed mortalities by species.

Figure 4 – Annual Mortalities by Species (includes feather spots)



One-hundred and twenty-seven (127; 97%) of the 131 observed mortalities could be identified to the family level. Of these 127 mortalities, the families Columbidae (52 mortalities; 41% of mortalities identified to family level) and Rallidae (43 mortalities; 34% of mortalities identified to family level) were the most commonly observed mortalities. **Figure 5** presents the breakdown of observed mortalities by family. **Figure 6** shows the proportion of mortalities that each family represents broken down by quarter.

Figure 5 – Annual Mortalities by Family (includes feather spots)

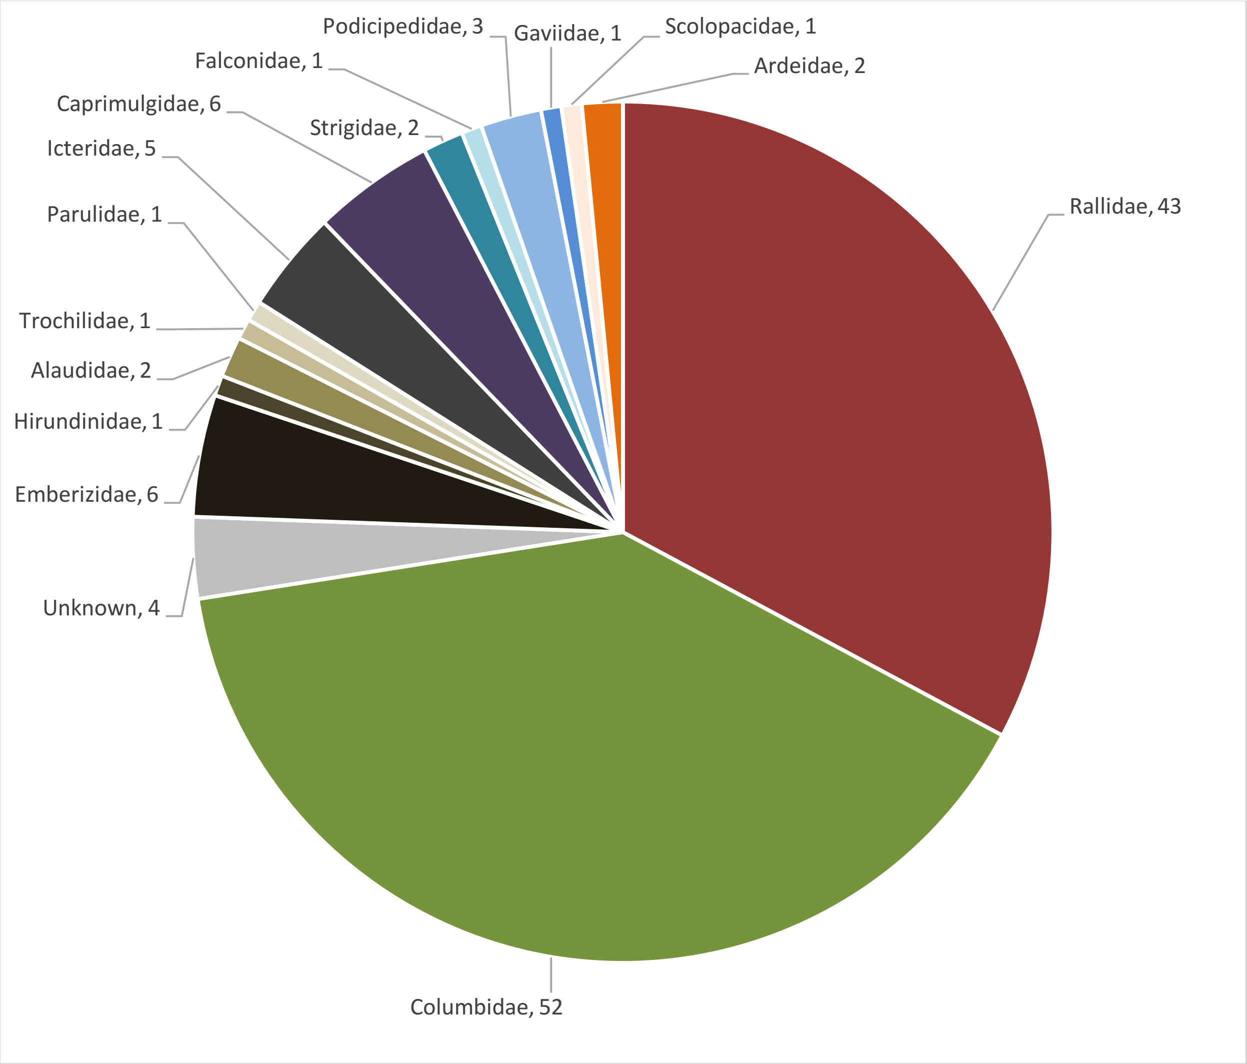


Figure 6 – Proportion of mortalities by family each quarter (includes feather spots)

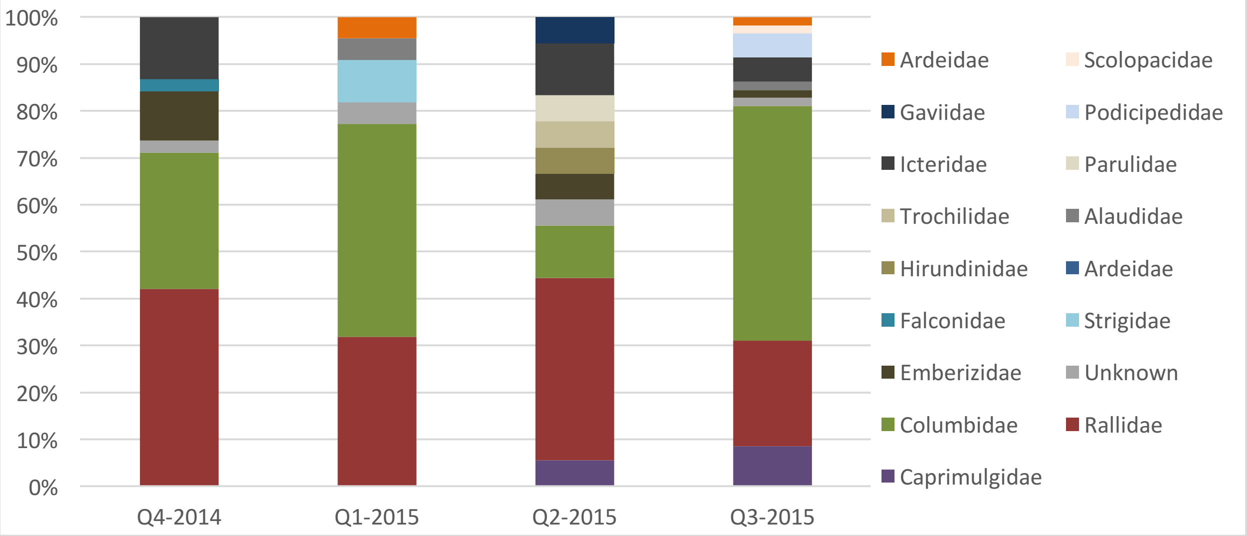
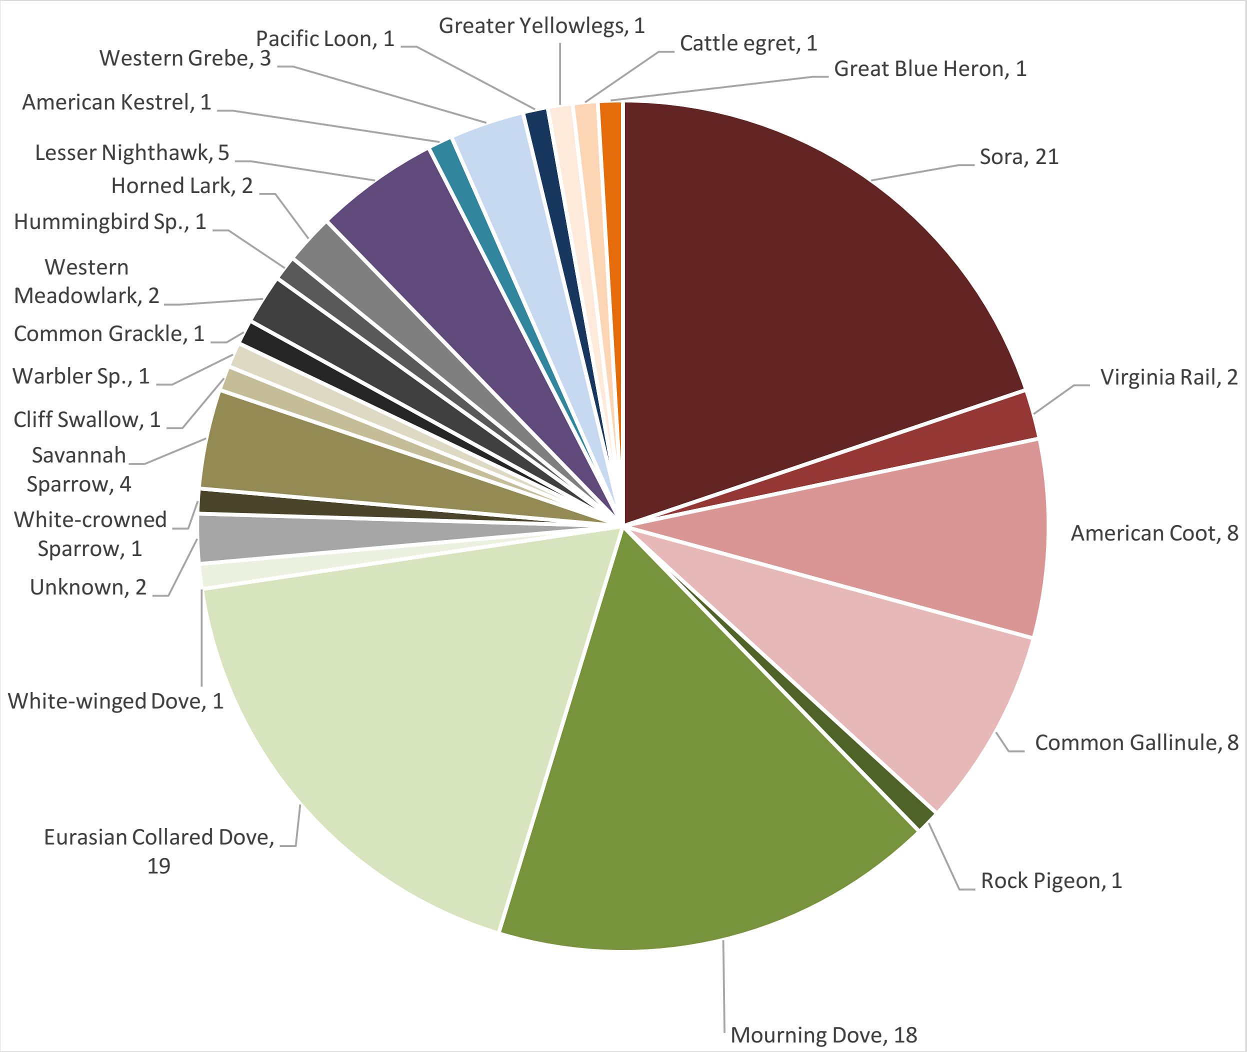


3.4.2 Mortalities Excluding Feather Spots

A total of 108 mortalities were observed when feather spots were excluded from the data set. One-hundred and three (103) of these mortalities (95%) could be identified to species. Of these 103 carcasses, the most commonly observed species were Sora (21 mortalities; 20% of mortalities identified to species), Eurasion Collard Dove (19 mortalities; 18% of mortalities identified to species), and Mourning Dove (18 mortalities; 17% of mortalities identified to species). **Figure 7** presents the breakdown of observed mortalities by species.

Figure 7 – Annual Mortalities by Species (excludes feather spots)



One-hundred and six (106) of the 108 observed mortalities (98%) could be identified to the family level. Of these 106 mortalities, the families Columbidae (40 mortalities; 38% of mortalities identified to family level) and Rallidae (39 mortalities; 37% of mortalities identified to family level) were the most commonly observed. **Figure 8** presents the breakdown of observed mortalities by family. **Figure 9** shows the proportion of mortalities that each family represents broken down by quarter.

Figure 8 – Annual Mortalities by Family (excludes feather spots)

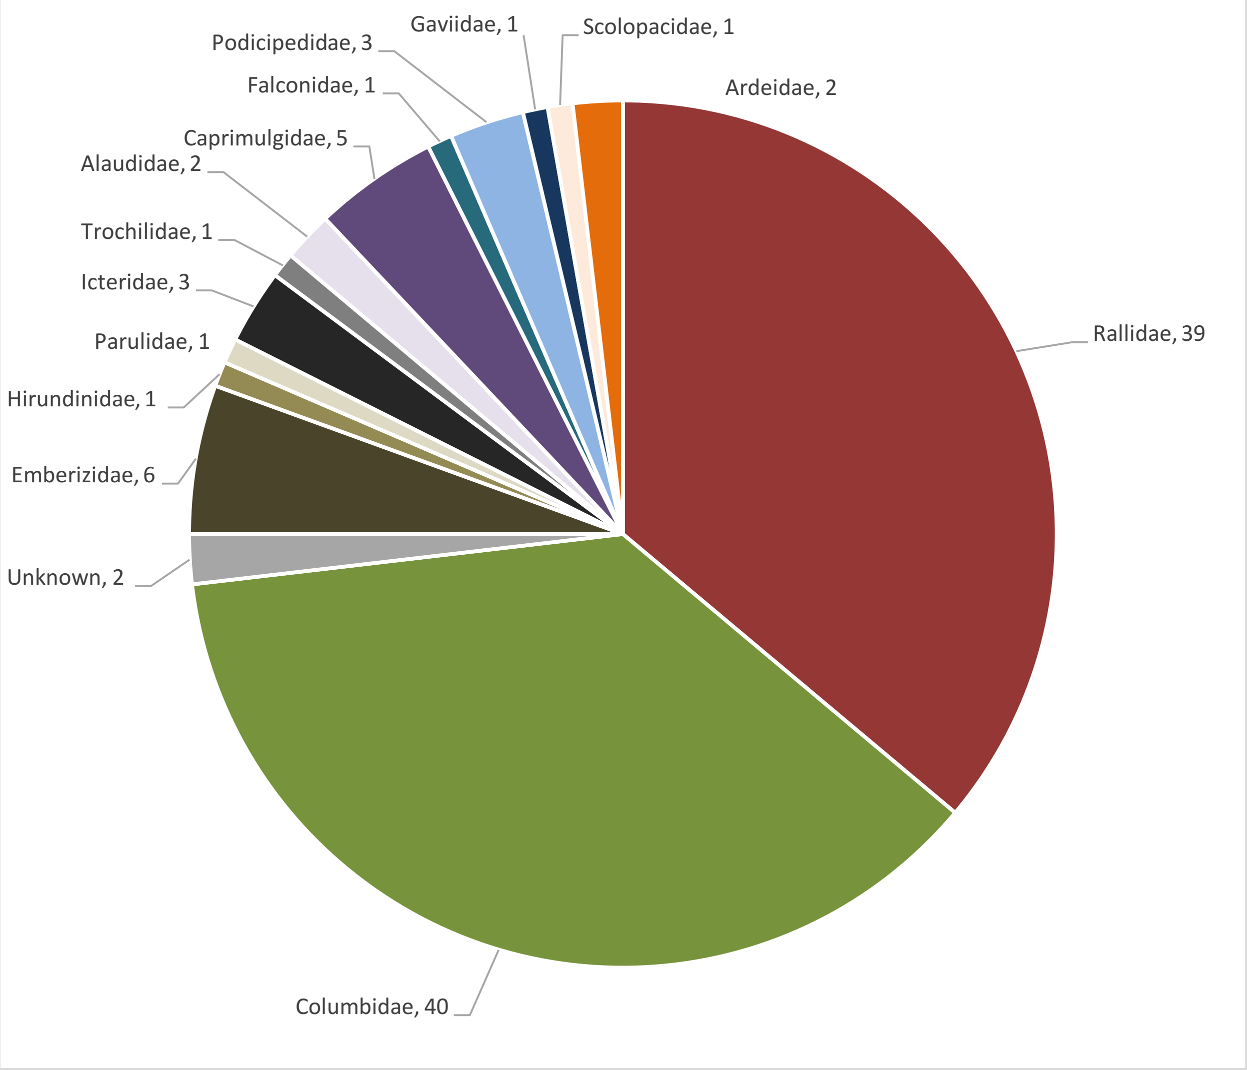


Figure 9 - Proportion of mortalities by family each quarter (excludes feather spots)

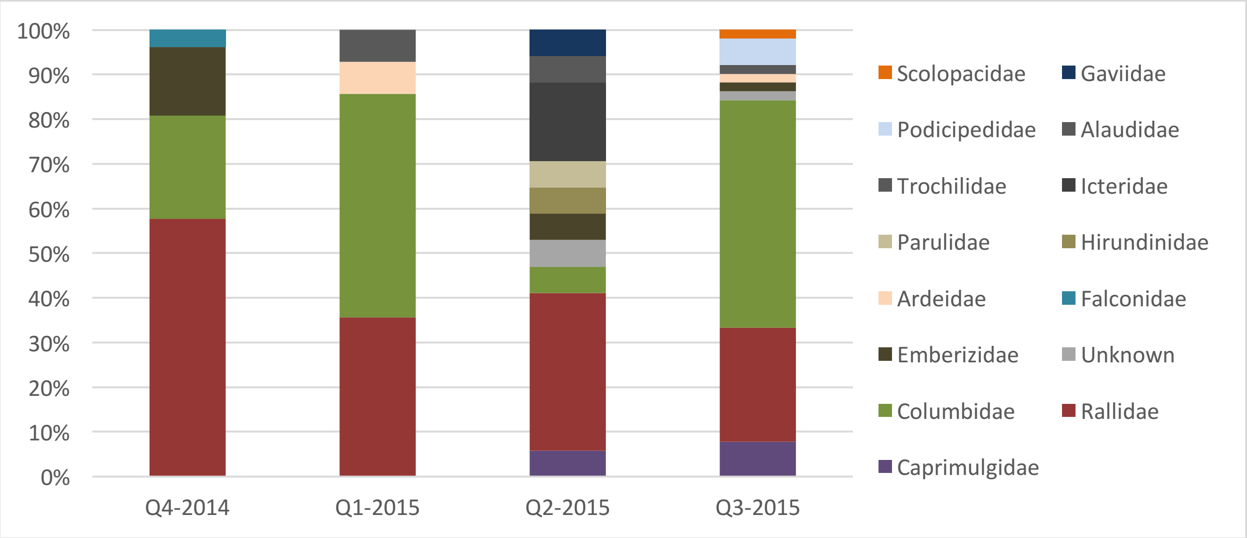

4 Discussion

4.1 Mortality Estimates

Because permit issuance allowing for detection probability estimation was delayed, this is the first report for the Campo Verde Solar Project that has incorporated the results of searcher efficiency trials and scavenger removal trials. These data were used to correct the overall estimated project mortality using the Korner-Nievergelt et al. (2011) method. This correction resulted in an overall project mortality estimate that was significantly higher than the uncorrected estimate (for estimates that both include and exclude feather spots), and they are likely a more accurate representation of actual mortality rates. Given the magnitude of this correction, previous results that were uncorrected should be used with caution.

Mortality estimates for this project are both inclusive and exclusive of feather spots. As is discussed above, estimates that include feather spots should be used with caution since most feather spot mortalities are unlikely to be attributable to the project. Similarly, the cause of death of the vast majority of mortalities was unknown. Thus, not all mortalities observed during surveys are definitively attributable to the project. For example, family Columbidae mortalities are much higher during the hunting season when dove hunting is regularly observed immediately adjacent to several portions of the project. The proportion of mortalities observed in this study that are directly or indirectly attributable to project infrastructure or activities is unknown.

The sample sizes associated with both searcher efficiency trials and scavenger removal trials were relatively small. Furthermore, the Korner-Nievergelt et al. (2011) method assumes constant detection probability over time. While this assumption is reasonable, it remains untested, as such these results should also be used with caution.

4.2 Seasonal Variations

Seasonal Patterns of seasonal variation were similar to those observed during the first year of surveys. There was strong variation month to month and a strong trend over the course of the entire second year. Both the datasets (including and excluding feather spots) showed a strong peak in corrected mortality rates during the fall months with September and October showing the greatest number of mortalities (September: 362/379 mortalities representing 15%/12% of all estimated mortalities; October: 683/733 mortalities representing 28%/24% of all estimated mortalities). Interestingly, no clear patterns in seasonal variations in taxonomic composition were apparent from the data (see **Figures 9 and 12**). The factors influencing this apparent seasonal peak are unclear but could include avian abundance fluctuations in the vicinity of the project, variations in avian behavior during the fall months (e.g. migration, foraging patterns), or an influx of juvenile birds in the project vicinity.

CARCASS DESCRIPTION

SPECIES: Red Tailed Hawk

SEX (*circle*): M F [✓ U] AGE (*circle*): A [✓ J] U Tag/Band Number: n/a

CONDITION (*circle*): intact scavenged dismembered feather spot [✓ injured]

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): >1 1 2 3 4 5 6 7 7+ [✓ unknown]

CAUSE OF ~~DEATH:~~ Injury.

Unknown - hawk was located near a public roadway + overhead powerlines.

OBSERVABLE INJURIES:

left wing appears broken, near distal end. Poor/limited flight. Low energy.

SUBSTRATE/GROUND COVER (*at carcass location*): n/a

DISPOSITION OF CARCASS[1] (*circle*): left in place removed collected for trials collected for other: brought to vetrinarian/rehab

SHIPPED TO:

[name of institution] Sky Hunters

[physical address] PO Box 1275 Lakeside, CA 92040

[phone/email] 619-445-6565

WEATHER CONDITIONS

AIR TEMPERATURE (degrees Fahrenheit): 80°

PRECIPITATON (last 24 hours, *circle*): [✓ none] light rain rain heavy rain hail snow

CLOUD COVER (*circle*): clear mostly clear partly cloudy mostly cloudy [✓ cloudy]

WIND DIRECTION: N SPEED (mph, *circle*): [✓ 0-10] 10-20 20-30 30+ gusty

NOTES (describe noteworthy weather conditions since last search, including high wind, fog, precipitation, and storm events):

none

PHOTOGRAPHS[2]:

Close Up: Photo 1 _______ Photo 2 ________

Landscape: Photo 3 _______ Photo 4 ________

PHOTO NOTES:

none → capture and transport were time sensitive due to the bird's injury - no time was taken for photographs.

NOTIFICATION[3]:

DATE: 1/23/13 TIME: 1400

NAME: Jim Thiede AGENCY/ASSOCIATION: USFWS

NOTES:

S. Yanco notified J. Thiede, USFWS of injured RTHA – Jim recommended Sky Hunters as appropriate rescue center and gave authorization for capture + transport of the individual. The hawk was brought to emergency vet facility associated with Sky Hunters per request of Nancy Conney, Sky Hunters.

---

[1] Permit required to handle bird carcasses.

[2] At least four photographs should be taken. Two should be close-in shots of the carcass and should be taken from at least two different angles. Two should be shots taken farther away showing the landscape (project components, surrounding habitat, etc.) and should be taken from at least two different angles).

[3] Indicate who was notified of the event, date, time, etc.

An injured Red-tailed Hawk was found about 6 miles east of the plant site ne of the Wiley's Well Rest Area during linear monitoring of a construction bore (11 N 0695179 3721231.) The bird was located beneath existing powerlines and may have been injured as a result of a powerline strike. The freeway is also close to where the bird was found.

CDFW was contacted and a reference was made to a Licensed Blythe Rehabilitation Location. Permission/Instruction was given to collect the hawk. The hawk was delivered for rehabilitation at approximately 1800. The contact person whom the bird was delivered to is Ms. Almquist, (760) 552-3239.

Thank you,

Eric German

1.0 INTRODUCTION

Desert Sunlight 250, LLC and Desert Sunlight 300, LLC (collectively, Desert Sunlight), has constructed and will operate the Desert Sunlight Solar Farm Project (Project), which consists of two main components: 1) a 550-megawatt (MW) photovoltaic (PV) generating facility; and 2) a 220-kilovolt (kV) generation interconnection (Gen-tie) line. The Project comprises approximately 1,700 hectares (ha; 4,200 acres) of land administered by the Bureau of Land Management (BLM) six miles north of Desert Center in Riverside County, California (Figure 1).

Information on pre-construction site conditions, avian and bat species present at the Project, risk assessment, and conservation measures implemented during pre-construction and construction phases are found in the Project's "Avian and Bat Protection Plan, Desert Sunlight Solar Farm Project, BLM Case File Number CACA-48649, Riverside County, California" (Ironwood Consulting 2011). The Avian and Bat Protection Plan (ABPP) was included as part of Appendix H in the Desert Sunlight Solar Farm Project, California Desert Conservation Area Plan Amendment and Final Environmental Impact Statement (USDI BLM 2011) and the Project received a Record of Decision from the Secretary of the Department of the Interior on August 09, 2011. Avian and Bat Protection Plans have since been renamed, and are presently known as Bird and Bat Conservation Strategies (BBCS). This BBCS replaces the ABPP and was developed in coordination with BLM to provide a written record of the Project's post-construction efforts to monitor potential project impacts to birds and bats and to document conservation measures that have been or will be taken to avoid, minimize, and/or mitigate for potential impacts. After introductory material on project description, the BBCS purpose, and regulatory framework, this BBCS addresses post-construction monitoring and adaptive management.

Figure 1. Location of the Desert Sunlight Solar Farm Project, Riverside County, California.

1.1 Purpose

The primary purpose of this BBCS is to describe post-construction monitoring protocols that will identify the extent of mortality and injury to bird and bat species and guide the adaptive management process intended to avoid, minimize, and/or mitigate impacts consistent with the Project's approval documentation. This BBCS includes the following objectives:

- Identify operational activities that may increase potential adverse effects to avian and bat species on and adjacent to Project components;
- Describe measures that were taken before and during construction to minimize and document mortality;
- Provide details for an avian fatality monitoring plan to be conducted post-construction, including applicable approved protocols that would be used for any surveys and/or monitoring;
- Specify the adaptive management process that will be used to address potential adverse effects on these species.

1.2 Regulatory Setting

Several federal and state laws and regulations, including National Environmental Policy Act (NEPA), the Endangered Species Act (ESA), the Migratory Bird Treaty Act (MBTA), the Bald and Golden Eagle Protection Act (BGEPA), and California Endangered Species Act, provide the foundation for the development of this BBCS.

1.2.1 National Environmental Policy Act

Under NEPA (42 United States Code [USC] §§ 4321-4370h), federal agencies are required to prepare an environmental impact statement (EIS) for any major federal action significantly affecting the quality of the human environment. An EIS must include an examination of the environmental impacts of a proposed project, a reasonable range of alternatives for a project, and other related matters. The environmental impacts of the Project have been addressed in the Final EIS and ROD (BLM 2011a,b). This BBCS implements Mitigation Measure (MM) WIL-5 in the Project's ROD.

1.2.2 Endangered Species Act

Certain species at risk of extinction, including many birds and bats, are protected under the federal ESA. The ESA defines and lists species as "endangered" and "threatened" and provides regulatory protection for the listed species. The ESA provides a program for conservation and recovery of threatened and endangered species. Section 7(a)(2) of the ESA directs all federal agencies to insure that any action they authorize, fund, or carry-out does not jeopardize the continued existence of an endangered or threatened species or destroy or adversely modify designated or proposed critical habitat (collectively, referred to as protected resources).

1.2.3 Migratory Bird Treaty Act

The MBTA (16 USC §§ 703, *et seq.*), makes it unlawful to “pursue, hunt, take, capture or kill; attempt to take capture or kill; possess; offer to or sell, barter, purchase, or deliver; or cause to be shipped, exported, imported, transported, or received any native migratory bird, part, nest, egg, or product.” The MBTA, enforced by USFWS, protects all MBTA-listed migratory birds within the United States. In the continental U.S., native non-covered species generally belong to the Order Galliformes. Common non-native species not protected by the MBTA include rock pigeon (*Columba livia*), Eurasian collared-doves (*Streptopelia decaocto*), European starling (*Sturnus vulgaris*), and house sparrow (*Passer domesticus*; USFWS 2005). Although permits may be obtained to collect MBTA-listed birds for scientific purposes or to destroy depredating migratory birds, the MBTA does not provide any permit mechanism authorizing the incidental take of migratory birds in connection with otherwise lawful activities. Nevertheless, federal agencies such as the BLM have been directed to evaluate the effects of its actions on migratory birds, with an emphasis on species of concern (per Executive Order 13186).

1.2.4 Bald and Golden Eagle Protection Act

The BGEPA (16 USC §§ 668-668d) prohibits the take, defined as “pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest, or disturb,” of any bald eagle (*Haliaeetus leucocephalus*) or golden eagle (*Aquila chrysaetos*). Through recent regulation (50 Code of Federal Regulations [CFR] § 22.26; USFWS 2009), the USFWS can authorize take of bald and golden eagles when the take is associated with, but not the purpose of, an otherwise lawful activity and cannot practicably be avoided. The USFWS has issued Eagle Conservation Plan Guidance (USFWS 2013a) for land-based wind energy projects to help project proponents avoid unanticipated take of bald and golden eagles and comply with the BGEPA. Although the guidelines were developed for land-based wind energy projects, certain components of eagle surveys and monitoring are applicable to other renewable energy projects, including PV solar plants, and have been incorporated into this BBCS as appropriate.

1.2.5 California Department of Fish and Game Codes

CDFG Code Sections 2050-2085 – These codes encompass the applicable declarations and definitions of the California Endangered Species Act (CESA).

CDFG Code Sections 3503 and 3503.5 – These codes state that it is unlawful to take, possess, or needlessly destroy the nest or eggs of any bird (including birds of prey) or take, possess, or destroy birds of prey, except as otherwise provided by this code or any regulation made pursuant thereto.

CDFG Code Sections 3511, 4700, 5050, and 5515 – These state laws classify and prohibit the take of “fully protected” bird, mammal, amphibian/reptile, and fish species in California.

CDFG Code Section 3513 – This code prohibits any take or possession of birds that are designated by the MBTA as migratory non-game birds except as allowed by federal rules and regulations promulgated pursuant to the MBTA.

CDFG Code Section 4150 – This code defines all mammals that naturally occur in California as non-game mammals with exceptions for those defined as game mammals, fully protected mammals, or fur-bearing mammals. Non-game mammals or parts thereof may not be taken or possessed except as otherwise provided by this code or any regulation made pursuant thereto.

1.3 Corporate Policy and Coordination

Desert Sunlight maintains a commitment to work cooperatively to minimize adverse impacts to protected bird and bat species. Through the planning and construction stages of the Project, Desert Sunlight and its contractors and consultants worked in coordination with federal and state agency personnel regarding necessary wildlife surveys, siting considerations, mitigation measures and adaptive management to ensure that potential issues that could affect bird and bat species were identified as early as possible in the planning process and addressed through appropriate design, mitigation and adaptive management measures. Desert Sunlight will continue to work with the agencies to implement conservation measures intended to avoid, minimize, and/or mitigate potential impacts to bird and bat species, including those measures identified in this BBCS.

2.0 PROJECT DESCRIPTION

The Project is a PV solar power plant being developed on approximately 1,700 ha (4,200 acres) of public land administered by the BLM in Riverside County, California, approximately 9.7 km (six miles) north of the rural community of Desert Center (Figure 1). Project construction is anticipated to be concluded on or about January 2015. The Project consists of two main components: 1) a 550 MW PV generating facility (Solar Farm) of solar equipment; and 2) a 220 kV Gen-tie Line. More specifically, the Solar Farm consists of 466 individual PV arrays, with each array occupying 2.4 to 2.8 ha (6 to 7 acres) and consisting of rows of PV panels supported on steel posts, a power conversion station, and a transformer. High-capacity 34-kV collection lines will transfer power output from the PV arrays to the onsite substation via overhead lines. The total acreage of the Project (including the Gen-tie Line) is 4,085 acres (1,653 ha). A chain-link fence topped with barbed wire encloses the entire Solar Farm, including support facilities (encompassing approximately 3,697 acres [1,496 ha]). The solar arrays cover 2,984 acres (1,208 ha).

In addition to the PV generating facility, other primary Project features include an operations and maintenance (O&M) building, visitor center, parking areas, access roads, fiber-optic lines, water wells, wastewater treatment facilities, an onsite electrical substation, and the 220 kV Gen-tie Line connecting the Project to the power grid.

Project features -- including solar panels, overhead electrical feeder and distribution lines, the Gen-tie Line, temporary retention basins, and the perimeter security fence -- pose potential mortality and injury risks to birds and bats. This BBCS focuses on permanent Project infrastructure elements including the solar panel arrays, perimeter fence and the Gen-tie Line. To minimize the threat of electrocution and collision, the Project's electrical distribution infrastructure is being built to avian-safe standards following Avian Power Line Interaction

Committee (APLIC) guidelines (APLIC 2005, 2006, 2012). Should birds or bats collide with the on-site distribution powerlines, injuries and fatalities will be documented during sampling of the solar arrays, as well as incidentally by Project staff during other activities.

3.0 SITE CHARACTERIZATION

The Project site is located in a relatively flat, previously undeveloped area of Chuckwalla Valley in eastern Riverside County. It is approximately 9.6 km (5.9 mi) north of Interstate 10 and the rural community of Desert Center, between the cities of Coachella to the west and Blythe to the east. Joshua Tree National Park wraps around the Project site to the west, north, and east; at its closest point, the Project is approximately 2.2 km (1.4 miles) southwest of the park boundary. Lake Tamarisk, a small golf-resort community, is approximately 6.4 km (four miles) to the south. The inactive Kaiser Eagle Mountain Mine is approximately 1.6 km (one mile) to the west.

The Project site is in the Colorado Desert Bioregion, which is the western extension of the Sonoran Desert of southern Arizona and northwestern Mexico. The Mojave Desert, which includes portions of Joshua Tree National Park, lies immediately north of the Project area. Chuckwalla Valley encompasses a series of alluvial fans that gently slope toward the southwest and southeast.

The 2011 FEIS prepared for the Project (BLM 2011a) describes the biological setting of the Project area. The FEIS included the results of biological surveys conducted in areas of potential impact associated with the Solar Farm, Gen-tie Line, Red Bluff Substation, and possible alternative sites (all collectively referred to as the Biological Study Area [BSA]). Before construction began on the Project, vegetation in the BSA consisted of Sonoran creosote (*Larrea tridentata*) bush scrub and desert dry wash woodland communities. To prepare for installation of the solar arrays, the Solar Farm site was disked and rolled, such that the Project landscape is now relatively flat and uniform, with vegetation re-establishing on the site. Stabilized sand sheets and pockets of sand dune deposits are located to the east of the Project area, but the Solar Farm site lacks wind-blown sand formations. Disturbed and developed areas that are either barren or dominated by ruderal vegetation occur primarily along roadsides. Agricultural areas, mostly fallow jojoba (*Simmondsia chinensis*) farms, are located southeast of the Project site.

Two temporary 0.4-ha (1-acre) ponds provided water during construction of the Project. One of the ponds was removed, and the second pond will be removed by the end of 2014. Several retention basins, which may hold water for some time after a storm event, are located within the Project’s perimeter security fence, along the western upstream boundary and on the southeastern downstream boundary. An open portion of the Colorado River Aqueduct runs around the north end of Chuckwalla Valley, from about six to 10 km (four to six miles) north of the Project site. An aquaculture facility, covering approximately 24 ha (60 acres), lies about three km (two miles) south of the Project site and contains perennially open water. The community of Lake Tamarisk includes homes, a golf course, and a small lake complex. The habitat structure and available water in this community routinely attract resident and migratory birds. All of these water features (when watered, in the case of the retention basins) can attract water-associated birds and shorebirds, either during migration stopover periods or in the course of local and intraregional movements.

4.0 CONSERVATION MEASURES IMPLEMENTED BEFORE AND DURING CONSTRUCTION

4.1 Pre-Siting Data Collection

In an effort to place the Project infrastructure in locations that would result in the least risk to populations of birds and bats, data on site characteristics and wildlife occurrence was collected and evaluated.

4.1.1 Coarse Site Assessment

In accordance with USFWS guidance, a siting evaluation of the solar farm site, Gen-tie line, and substation was completed. The Project conducted the equivalent of a Potential Impact Index (USFWS 2003) by evaluating suitability of the site proposed for development and estimating use of the site by selected wildlife species as an indicator of potential impact (USFWS 2010). Initial biological assessments conducted in 2007 recommended avoidance of Pinto Wash as potential habitat for special status species, and this assessment was supported during a site visit in 2010. Several modifications to Project design occurred that reduced the proposed Project footprint and moved it away from areas suspected to contain high-quality habitats for birds or bats. Alternative sites for the solar farm, Gen-tie line route, and substation were confirmed to occur outside any Important Bird Areas, Western Hemisphere Shorebird Reserve Network sites, and areas designated by the Convention on Wetlands of International Importance. The Gen-tie line and substation alternatives are located within the Chuckwalla Desert Wildlife Management Area and Critical Habitat Unit designated as management areas for desert tortoise.

4.1.2 Habitat Equivalency Analysis

A Habitat Equivalency Analysis (HEA) was conducted to quantify potential temporary disturbance versus permanent loss of habitat and to guide the habitat compensation process. The most significant step the Proponent took to promote wildlife conservation during this process was to coordinate with the BLM to determine suitability of habitat remaining within the solar application as area to be excluded from future development due to biological concerns.

4.1.3 Site-Specific Wildlife Surveys

As recommended by USFWS (2010), multiple survey techniques were used to collect baseline data on wildlife populations at the Project. Specific survey methods included:

- Diurnal point counts, conducted in April, May, and October 2010
- Raptor nest searches including golden eagle surveys (Pagel et al. 2010), conducted in April and May 2010

- Reconnaissance-level survey of Project components to determine which bat species could occur at the site
- Incidental data collection conducted during all biological surveys in 2010; additionally, incidental observations were collected over four years of activity at the Project

Thirty-eight passerines were recorded during baseline surveys. The only special-status species recorded were Brewer's sparrow (*Spizella breweri*), Costa's hummingbird (*Calypte costae*), and Le Conte's thrasher (*Toxostoma lecontei*). All three species are listed as USFWS Birds of Conservation Concern (BCC; USFWS 2008). Thirteen raptor species were documented, including California Species of Special Concern: burrowing owl (*Athene cunicularia*), loggerhead shrike (*Lanius ludovicianus*), and northern harrier (*Circus cyaneus*; CDFW 2008). Swainson's hawk (*Buteo swainsoni*) was also recorded, which is state-listed as threatened (CDFW 2014), along with federally-protected golden eagle (*Aquila chrysaetos;* BGEPA 1940). Surveys for bat habitat suggested that pallid bat (*Antrozous pallidus*), canyon bat (*Parastrellus hesperus*), hoary bat (*Lasiurus cinereus*), and California leaf-nosed bat (*Macrotus californicus*) could potentially occur at alternative sites given the habitat present. The list of most common species observed is found in Figure 2.

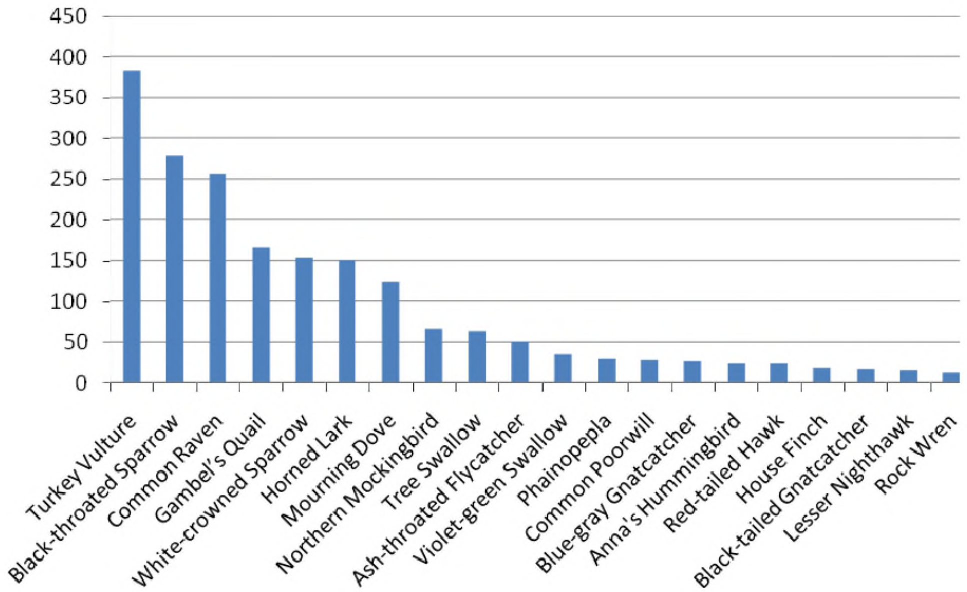

Figure 2. Avian species most frequently encountered during baseline surveys at Desert Sunlight Solar Farm Project, Riverside County, California.

5.0 CONSERVATION MEASURES

5.1 Project Siting

The process of siting the Project components included both macro- and micro-siting considerations. Macro-siting considerations occurred in 2007 during initial site surveys and were refined in 2008 after review of data. During this process, Pinto Wash and other larger areas of desert wash woodland were removed from Project consideration because they were deemed likely to support greater numbers of species or individuals than other habitats in the Right-of-Way area. Macro-siting considerations also included avoidance of:

- Locations with special status species and areas managed for the conservation of listed species
- Areas frequently used for daily bird and bat movements (e.g., areas between roosting and feeding sites)
- Breeding and wintering eagle use areas
- Known migration flyways for birds and bats
- Areas near known bat hibernacula, breeding, and maternity/nursery colonies
- Fragmentation of large, contiguous tracts of wildlife habitat

Micro-siting consideration for the Project components began in 2008 and continued as wildlife surveys were conducted and through informal meetings with the BLM, USFWS, and CDFW throughout the Project's planning process. Siting was also refined in response to concerns from the public and agencies involved in the process. Additional considerations of micro-siting included:

- Avoiding features that attract raptors (i.e., areas supporting tall perching structures including trees, utility poles, etc.)
- Avoiding features that attract migrant birds (e.g., water sources and vegetation)
- Minimizing the potential for enhancing habitats suitable for raptor prey such as rodents that would potentially attract raptors to the site.

5.2 Facility Design

Many conservation measures were incorporated into the design of Project facilities to reduce the potential effects of Project infrastructure on bird and bat populations, including:

- Avoidance of lattice-type structure or placing external ladders and platforms on towers to minimize perching and nesting
- Avoidance of meteorological towers with guy wires
- Minimal lighting and where lighting was necessary, facility lighting focused down ward to reduce sky illumination
- Power lines built in accordance with guidelines from the Avian Power Line Interaction Committee

- Minimal creation of new roads

5.3 Construction Phase Conservation Measures

Conservation measure implemented by the Project during construction included:

- Minimization of permanent disturbance area by minimizing creation of roads, avoidance of excessive clearing of vegetation, and grading whenever possible
- To the extent practicable, clearing of vegetation took place outside the bird breeding season. When not practicable, the Desert Sunlight communicated reasons to BLM, USFWS, and CDFG and provided a biological monitor to locate active nests, establish buffers, and stop construction when necessary when Project activity threatened a nest. Buffer distances of 100 m (330 ft), 152 m (500 ft), or one mile were used for active passerine, raptor, and golden eagle nests, respectively.
- Clearance surveys to locate and identify active nests or bat colonies
- Surveys for golden eagle nests conducted during each year there were construction activities within the nesting season
- Clearance surveys for burrowing owls completed in each construction unit and including a 150-m buffer area
- Mandatory site training for all construction personnel regarding avoidance of nests and bat colonies
- Following APLIC guidelines for overhead utilities
- Conducting construction activities in a manner consistent with reducing fire danger
- Trash promptly removed and disposed of to avoid creating attractions for birds or bats
- Established and implemented an Integrated Weed Management Plan (Ironwood Consulting 2010a)
- Used native species for seeding and planting during re-vegetation efforts

6.0 Incidental Avian Mortality Information during Construction and Early Operation

As of Oct 31, 2014, 198 avian and bat injuries or mortalities have been documented on-site during construction of the Project (Appendix A, First Solar 2014). Avian mortalities are being reported by construction workers and other staff incidental to their work activities. Consequently, the incidental nature of the data needs to be considered when evaluating the information reported to date. Data collected incidentally do not provide enough information to accurately quantify the scope of actual avian mortalities on a project site. However, these data can provide important information such as the composition of species which may be at risk in the future. In addition, the data provide insights into project features and types of injuries that may be associated with fatalities (U.S. Fish and Wildlife Service 2014). The majority of fatalities documented on the Project site are water-associated taxa (SPUT data). However, whether this pattern is representative of overall composition of fatalities at the Project remains to be determined through standardized monitoring.

7.0 POST-CONSTRUCTION MONITORING PLAN

This section outlines a standardized approach to document known and projected bird and bat fatalities and injuries, and to estimate seasonal and annual post-construction fatality rates associated with Project features. The Plan includes an approach to determine whether there are spatial patterns of fatality rates within the solar field (i.e., different fatality rates near panels on the edge of the solar arrays vs. the interior area of the arrays). The Plan is consistent with the Bird Monitoring and Avoidance Plan outlined in the Project's FEIS (BLM 2011a), and builds on standards and guidelines developed for the electric-utility and renewable-energy industries to quantify the risk of fatality and injury for birds and bats that may result from interactions with energy-related infrastructure (e.g., Anderson et al. 1999; APLIC 2005, 2006, 2012; California Energy Commission [CEC] and CDFG 2007; USFWS 2010, 2012). In particular, the Plan outlines a statistically sound spatial and temporal sampling plan, including protocols for independently estimating and correcting for quarterly searcher-efficiency and seasonal (i.e., at least quarterly) scavenger (avian and mammalian) removal rates. It describes specific data to be collected during scheduled carcass searches, protocols for handling any dead or injured birds and bats that are found, and procedures for reporting incidents to relevant government agencies. The study design is compatible with the BLM (2011b) Record of Decision requirement (MM-WIL-05) that, after the study is complete, Desert Sunlight will ultimately submit a description of the study design and monitoring results to peer-reviewed scientific journals.

7.1 Goals and Objectives

Primary goals of the post-construction fatality monitoring program are to:

1. Estimate overall annual avian fatality rate and species composition associated with the Project infrastructure. This estimate will include mortality associated with solar arrays, overhead lines including the Gen-tie Line, perimeter fence and other features of the Project that may result in injury and fatality.
2. Determine whether there are spatial and temporal/seasonal patterns of mortality associated with project infrastructure (e.g., different fatality rates near panels on the edge of the arrays vs. the interior area of the arrays).
3. Provide information that will assist the BLM in consultation with the USFWS in understanding which species and potentially which regional populations are at risk.

4. Collect data in such a way that the BLM in consultation with the USFWS may make comparisons with other solar sites.

These goals are structured in a way that provides information on seasonal differences in fatality rates, and information about which taxonomic groups are most vulnerable. Fatality estimates will be adjusted to address carcass persistence and searcher efficiency as they change through seasons. Additionally, carcass persistence trials will inform search intervals.

Consistent with the above goals, the specific objectives of this Plan are as follows:

2. Conduct fatality searches for a minimum of 2 years according to a spatial and temporal sampling plan that provides representative and statistically sound coverage of the solar arrays, consistent with monitoring required of other industries. The need for additional monitoring beyond the second year will depend on an evaluation of the survey results from the first 2 years to determine if the goals of the monitoring program have been met (see Section 10.0, Adaptive Management). The need to extend the monitoring period will be determined by the BLM in consultation with the USFWS. To the extent possible, standardized monitoring, as approved by the BLM in consultation with the USFWS, will commence within 30 days of 1) date a final BBCS has been approved, and 2) the commercial operation delivery (COD) date (anticipated January 2015). Implementation of any agency required pre-monitoring meetings, training and searcher efficiency/carcass removal trials may extend the start of monitoring beyond 30 days after the BBCS is deemed final.
3. Conduct statistically sound, seasonal assessments to quantify and evaluate carcass removal rates (i.e., carcass removal, destruction including dismemberment, or burial in sand due to scavengers, decay, or other abiotic [e.g., wind] or human [e.g., vehicle activity] factors) and support calculation of adjusted fatality rates that account for variation in carcass removal rates by season and carcass type/size classes. These assessments will also be used to guide search intervals.
4. Use current, scientifically validated and accepted methods for calculating fatality rates adjusted for searcher-efficiency, carcass removal rates, and spatial and temporal sampling intensity. At present, the best methods are distance sampling combined with searcher efficiency and carcass removal bias adjustments and a fatality estimator such as the Shoenfeld (2004) or Huso (2012) estimators, but it should be noted that fatality estimation is an area of active research and 'best methods' are changing rapidly. Therefore, as data are collected, adaptive management of the study design and monitoring protocol may be necessary and will follow the process in Section 10.0.
5. Summarize the species composition of fatalities according to taxonomic family, and ecological guild (e.g., raptors, water-associated birds, passerines, etc.) to aid in understanding species or groups at risk.
6. To the extent possible, summarize the composition of fatalities according to their likely propensity to collide with project components during the day vs. during the night based on known migratory patterns for the particular species.

7. Aid in identifying potential fatality causes and correlates by including additional information that is readily available beyond that which is under the SPUT such as the weight of fresh whole birds, or summaries of preceding weather conditions which would have made migration likely (e.g., low pressure systems moving cross continent to the north of the project area, followed by periods of high pressure systems).
8. Data summaries, and accompanying raw data, and any GIS shapefiles will be reported to the BLM with each seasonal report.

7.2 Monitoring Methods

A monitoring program will be implemented for at least 2 years post-construction as specified below. Survey results and analysis will inform adaptive management decisions regarding any additional appropriate and practicable BBCMs to avoid, minimize, and/or mitigate for observed impacts.

7.2.1 Post-Construction Monitoring of Solar Arrays

The fundamental characteristics of a sampling program designed to produce valid estimates of fatality rates for a solar farm (including the number of arrays to be searched, the search interval, the seasonal extent of coverage, and the number of years of sampling) are determined based on several factors. These factors include the questions of interest; the species of interest (e.g., resident, migratory, and/or wintering species) in the Project area, desired precision, best estimates of carcass-removal rates, searcher efficiency, the Project size and layout, and other relevant environmental (i.e., seasonal patterns), landscape, and habitat characteristics.

The following hierarchical terminology is useful for describing the spatial and temporal sampling design used to monitor solar arrays:

1) **Panel Cartridge:** An engineered assembly of solar panels installed as a single unit (approximately 2.5 x 2.9 meters [m; 8.2 x 9.5 feet (ft)]).
2) **Row:** A collection of panel cartridges arrayed side-by-side on a common, linear support structure (variable lengths ranging from approximately 71 to 142 m [232 to 464 ft]).
3) **Section or Subarray:** A collection of usually 20 commonly energized rows that represent one quarter of a typical array; dimensions (on the order of 71 x 84 m [232 x 274 ft]) are mostly uniform within blocks, but vary slightly among blocks; in most cases, structurally continuous rows span sections of two adjacent arrays.
4) **Array:** A collection of four sections connected to a common power converter station (PCS) and transformer, encompassing 2.4–2.8 ha (5.9-6.9 ac), depending on subsection dimensions and spacing between subsections (i.e., 466 total units in the Solar Farm).
5) **Block:** Collections of commonly energized arrays (20 blocks, each composed of 11–32 arrays).

7.2.2 Survey Strategy

Sampling strategies used in carcass searches have typically involved transect sampling, whereby searchers walk or drive along pre-defined transects and search for carcasses in a swath where width depends on visibility, target taxa, and other factors. The layout of PV facilities presents problems for a transect-sampling approach because rows of panels are close together (i.e., less than 5 m [16 ft] at the Project). Because the panels are mounted off-horizontal, a searcher walking or driving a transect between two rows can only effectively search one side of the transect (a 2.5-m [8.2-ft] swath), and the other side is obscured by the edge of a PV cartridge. However, traveling perpendicular to panel rows along the edges of the rows allows observers to see a greater distance of the ground beneath the panels. Surveyors will walk or drive the lines in air-conditioned vehicles. Should driving surveys be used, searcher efficiency trials will be conducted prior to implementation; results will be submitted and evaluated by the BLM and FWS within 2-weeks of completion of the trials to determine if conducting surveys using vehicles is acceptable. Other accommodations may be required to enable completion of surveys during high temperatures, such as shifting surveys to dawn and dusk.

The layout of PV facilities is well-suited to a distance-sampling approach. Distance sampling involves searching a transect line and assumes that searcher efficiency decreases (possibly dramatically) as a function of distance from the observer, and is ideally suited to situations in which animals (or carcasses) are sparsely distributed across a landscape (Buckland et al. 1993). The landscape at the Project is flat and relatively clear of vegetation, which should support a distance sampling design.

Distance sampling adjusts carcass counts for variable searcher efficiency by accounting for the *effective* area searched along a transect. Effective area is the total area searched multiplied by the average probability of detection in the searched area. As a highly simplified example, if a searcher walks a 10-m long transect line and detects 90% of all carcasses within 10-m of the line, and 60% of carcasses that are 10 to 20 m (33 to 66 ft) from the line, then the effective area between zero and 10 m would be $10\,m \times 10\,m \times 0.9 = 90\,m^2$ and the effective area searched between 10 and 20 m would be $10\,m \times 10\,m \times 0.6 = 60\,m^2$. For the total 10 by 20-m area searched, the adjustment factor would be $\frac{90\,m^2 + 60\,m^2}{100\,m^2 + 100\,m^2} = 0.75$. In practice, searcher efficiency is modeled as a continuous function of distance, and the detection function is estimated from the carcass data (as opposed to a bias trial). The searcher efficiency bias trials can be used to augment carcass data for the detection function. If the detection function calculated from the bias trials differs from the detection function calculated from the carcass data, this suggests non-random distribution of carcasses within the arrays, and simultaneously provides an adjustment factor to account for non-random distribution of carcasses. Preliminary data from the California Valley Solar Ranch (CVSR) suggests that non-random carcass distribution may not be a problem at PV solar facilities (H.T. Harvey and Associates 2014). One advantage to a data-driven detection function is that it is not necessary to specify a transect width: the detection function includes information about the distance at which searcher efficiency drops to zero. The detection function is used to determine the overall probability of detection as well as to inform the approximate effective view shed of non-zero detection probability for observers.

7.2.3 Spatial Sampling Design

The sampling design is intended to follow to the USFWS Land-Based Wind Energy Guidelines (2012), which states that “the carcass searching protocol should be adequate to answer applicable Tier 4 questions at an appropriate level of precision to make *general* conclusions about the project*, and is not intended to provide highly precise measurements of fatalities*” (p. 45; emphasis added). Under the proposed sampling plan, precision is expected to vary based on carcass detectability: less precision is expected for estimates of small-bird fatality compared to estimates of large-bird fatality. However, monitoring programs at two other PV solar facilities (CVSR and Topaz) suggest that the level of impact for small birds due to PV was not very extensive, and was similar in composition and rates than what was found on control plots for passerines.

The sampling design is based on a statistical precision analysis using data from CVSR, as well as a simulation-based analysis that was informed by searcher efficiency and carcass removal rates in the Mojave desert region (Appendix B). Sampling effort that includes 20% of the solar arrays is expected to produce a reasonable coefficient of variation (CV = 100% * standard deviation / mean) (~20%) if fatality rates are greater than 1.0 fatality / MW / year, and the search interval is at most 21 days. This level of precision is generally considered adequate for answering the primary questions of interest in fatality monitoring studies (Strickland et al 2011).
Based on the simulation analyses, data from CVSR, consultation with relevant permitting and wildlife agencies, and consideration of the characteristics of this particular Project, sampling will encompass approximately 30% of the completed solar arrays as summarized in Table 1.

Table 1. Solar array sampling area characteristics.

Total area	1,208 ha
Proportion sampled	30%
Sampling unit	~2.6-ha spatial equivalent of 1 array
Number of sampling units (whole facility)	466
Migration season search interval (March 1 thru May 31, September 1 thru October 31)	7 days unless adjusted by BLM in consultation with the Wildlife agencies based on results carcass persistence trials.
Non-migration season search interval (June 1 thru August 31, November 1 through Feb 28)	21 days unless adjusted by BLM in consultation with the Wildlife agencies based on results of carcass persistence trials.
Anticipated surveys per year	31
Duration of sampling	Minimum of 2 years

Because both the layout of the solar arrays and the landscape of the Solar Farm (i.e., mostly flat and free of vegetation) are largely uniform, a relatively simple random sampling design is likely to be adequate for sampling the arrays. However, in the absence of data, a spatially balanced sampling design will be used. Because spatially balanced designs ensure that sample effort is distributed over the whole study area, they help to ensure that spatially organized trends in mortality–should they exist-- can be extracted from the data. The drivers of spatial variation in avian activity may be important to the statistical sampling design if avian use patterns affect the distribution of mortalities on the project site. As an example, factors that may affect avian use patterns include: 1) habitat variation around the Project site; 2) the possibility that distinct movement corridors variably concentrate birds over certain areas of the Project site (e.g., migrating or commuting water-associated birds); or 3) use of distribution lines (and other transmission line infrastructure) as roosting sites. Distribution lines within the solar field may also pose a collision risk to birds. To achieve spatially balanced sampling, the site will be divided into 10 approximately equal-sized sampling areas and sampling will be stratified among those areas. Sampling will also be stratified proportionally among areas with distribution lines and those without.

The sampling units for the surveys consist of areas equivalent in size to a single array, but because of the concatenation of panel rows across arrays, they may include conjoined sections from multiple individual arrays (Figure 3). Within sampling areas, individual sampling units will be randomly selected to compose a 30% sample (± 1–2%).

Observers will survey sampling units from the outer edges of collections of continuous solar panel rows and scanning between each row for fatalities, with each side-specific survey covering half the width of the sampling unit (Figures 3 and 4). Surveys will occur along roadways that run approximately north–south (consistent with the “Bio Blitz” report; USFWS

2013) through the middle of most arrays and along the outer edges of some arrays. Most sampling units consist of combined array sections from four adjacent arrays. In most cases, the four sections run together both north to south and east to west, forming a continuous block composed of 40 continuous panel rows that are approximately 140 m- (460-ft) long. In these cases, two north-south routes will comprise the sampling-unit survey, with each route involving scanning across a maximum of 70 m (230 ft; Figure 3). Other sampling units have an additional roadway and powerline corridor running through the middle, such that the sampling unit consists of two subsections, each composed of 40 panel rows that are approximately 70 m long. In these cases, four north-south routes will comprise the sampling unit survey, with each route involving a maximum scanning distance of 35 m (115 ft) covering half the width of a subsection (Figure 3). For a few other sampling units with different layouts along the perimeter of the Solar Farm, the analysis will need to take into account the potentially different row lengths. Distance sampling and resulting data will be used to calculate detectability curves to calculate the average detection probabilities, and taking into account the potential for different detection curves depending on the direction of the survey viewshed.

Given the results of an initial detectability field trial (see below), the expectation is that effective sampling for larger birds (1000+ grams) will extend the full width of all sampling units, whether composed of 140-m or 70-m long panel rows. For smaller and possibly medium sized birds (0-100 grams and 101-999 grams) and bats, however, effective sampling is expected to be constrained to less than the maximum viewing distance. Density estimation using distance sampling techniques is easier, and can be accomplished with greater precision if the data are truncated at a distance beyond which the probability of detection is low (Buckland et al. 1993). Accordingly, data will be truncated and the density of carcasses in the effective search area will be used to calculate the density of carcasses in the whole solar facility.

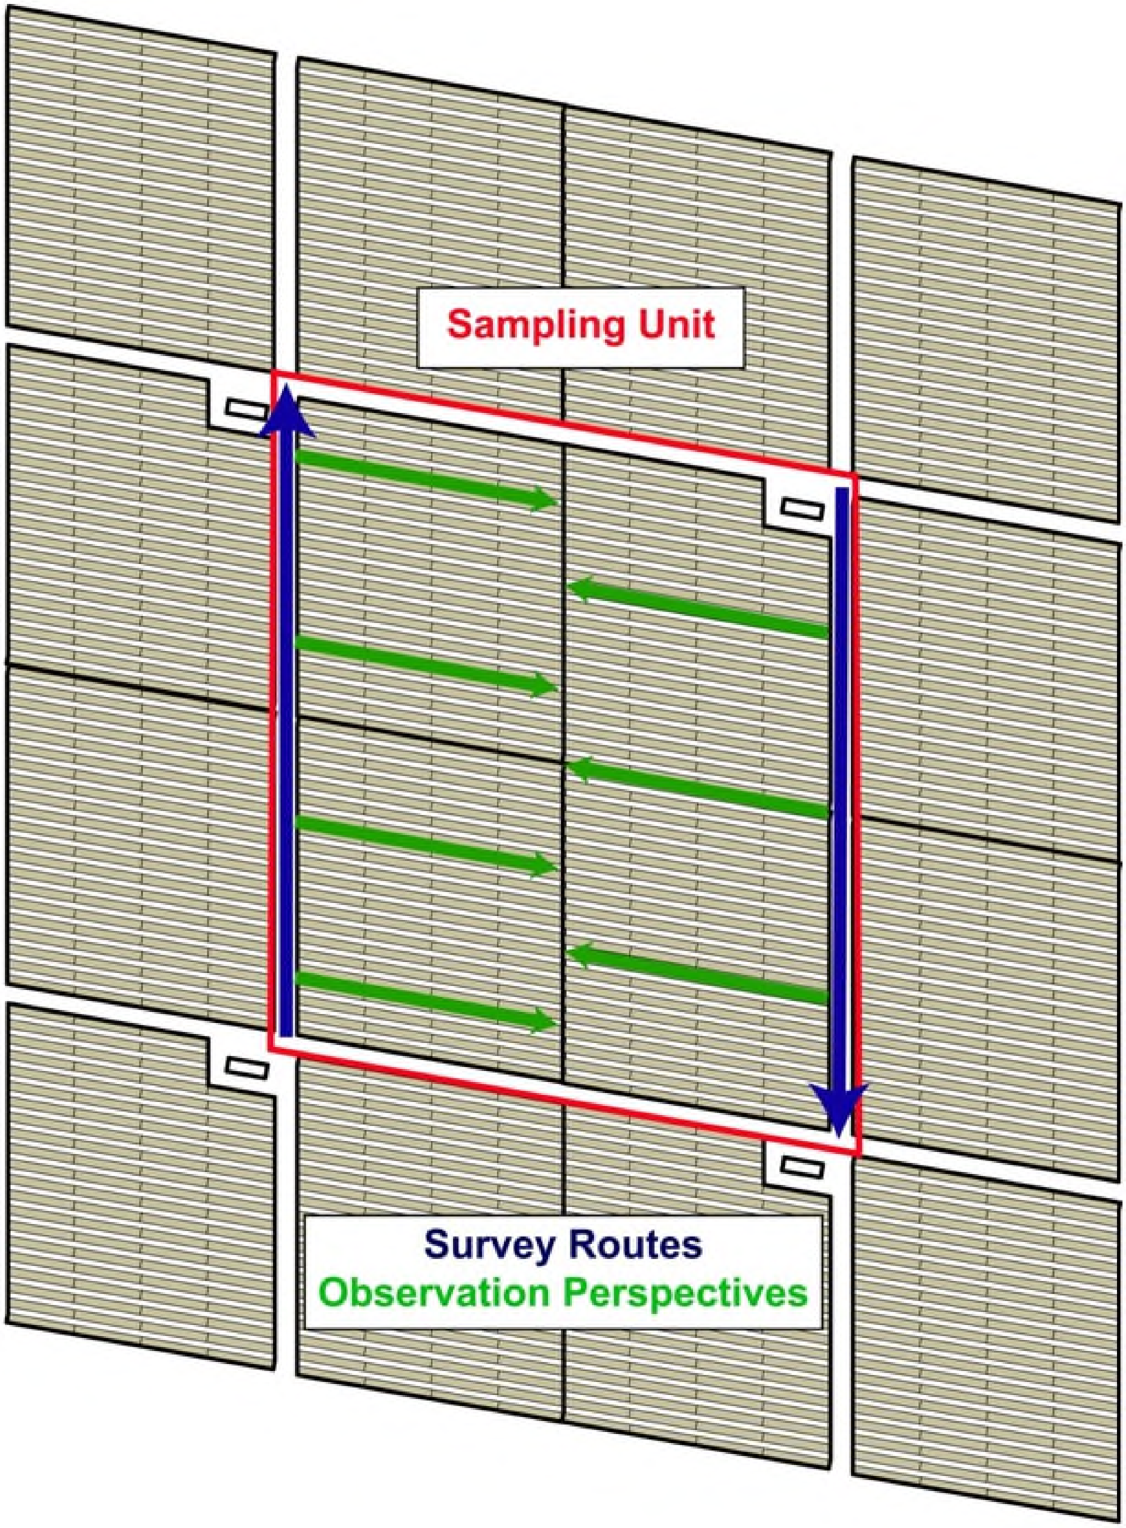

Figure 3. Illustration of a typical sampling unit and perimeter survey with travel routes and search areas (‘observation perspectives’).

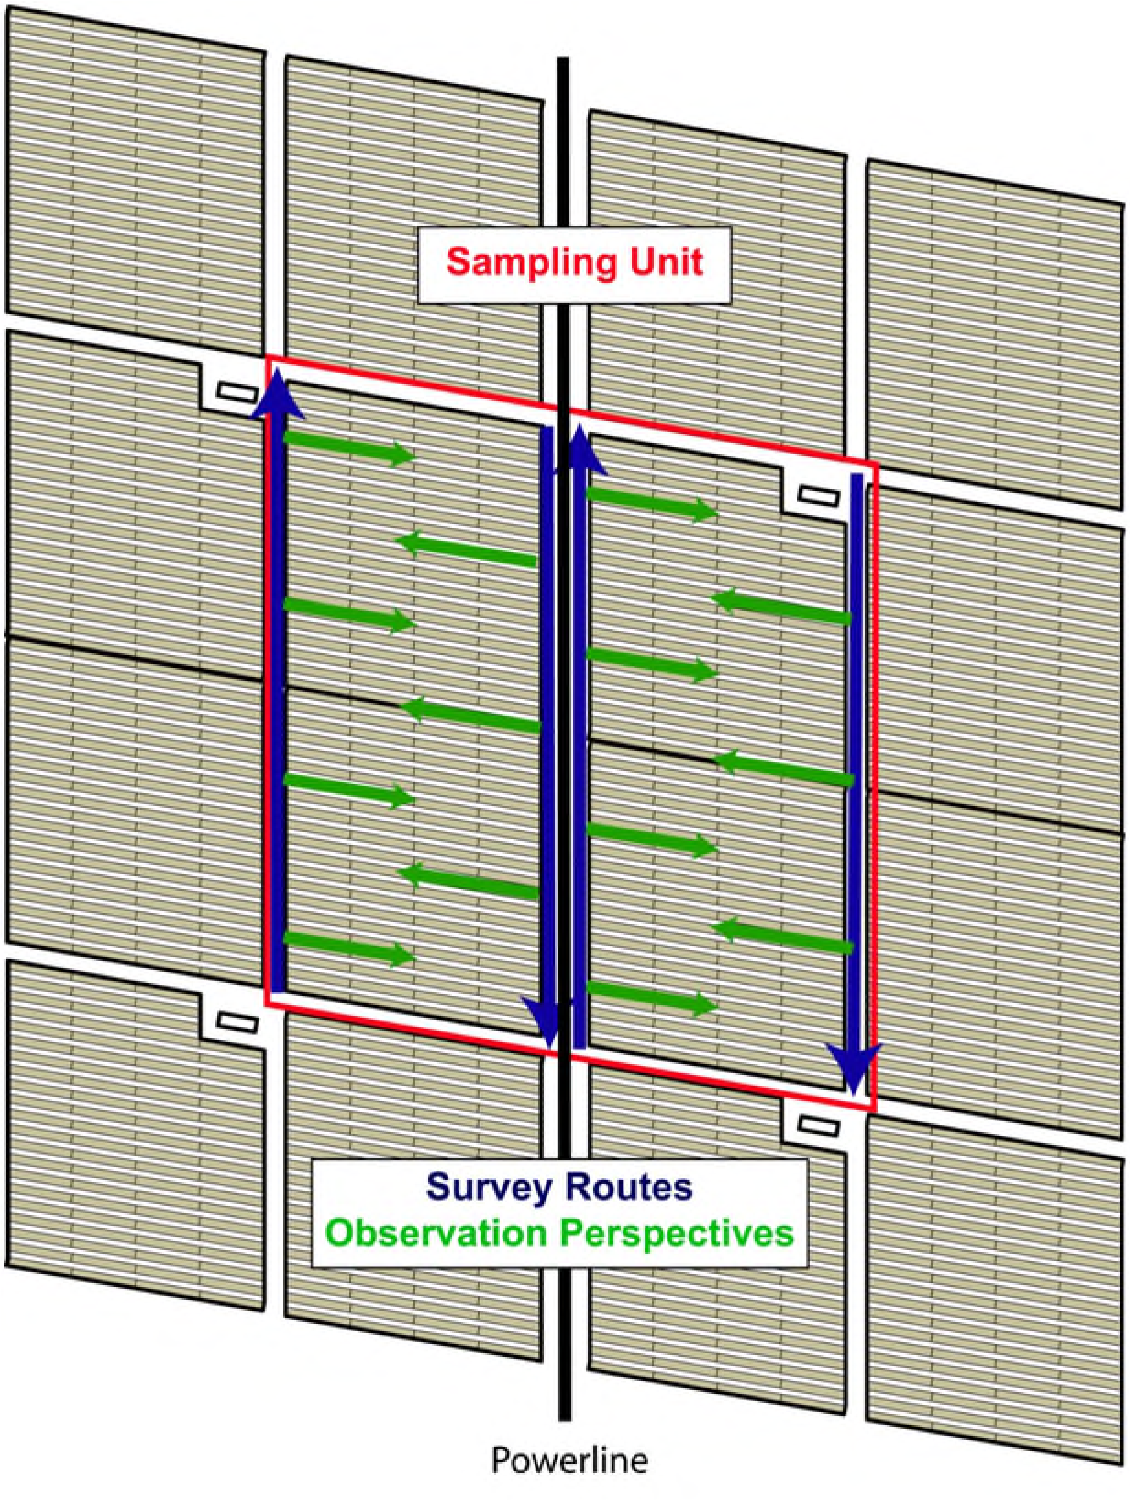

Figure 4. Illustration of a sampling unit survey including a distribution powerline with travel routes and search areas ('observation perspectives').

The perimeter-only survey design reflects two concerns: 1) minimizing movement between rows of solar panels. Because the area between electrified panel rows is an area of elevated risk, best practices dictate that personnel do not enter elevated risk zones unnecessarily; and 2) achieving an effective balance between logistic efficiency and sampling rigor given the constraints of transect spacing due to the width of panel rows. In support of the latter objective, a field trial was conducted to evaluate the ability of observers to detect carcasses of different types and sizes based on perimeter-only surveys that did not require walking between the rows of panels (H.T. Harvey and Associates 2013c). The field-trial surveys involved walking along the north-south edges of array sections perpendicular to the rows of panels and using naked-eye and binocular-aided scanning to search for placed carcasses of five non-native bird species, ranging in size from small house sparrows (*Passer domesticus*) to large ring-necked pheasants (*Phasianus colchicus*).

The field trial confirmed that, given the relatively flat, sandy, and uncluttered substrate that characterizes most of this solar facility, relatively large carcasses, such as rock pigeons (*Columba livia*) and pheasants, can be reliably detected (average detection probability over a 70–m wide transect > 0.75; Figure 5) using perimeter-only surveys, even when the continuous span of the solar-panel rows is 140 m, which applies across most of the facility. For smaller carcasses up to the size of small quail (*Coturnix japonica* in this case), however, detection probabilities will be much more strongly a function of distance (average detection probability over a 70–m wide transect > 0.35; Figure 5). Distance sampling is well-equipped to estimate population sizes, even when the detection function indicates a rapid decay in detectability with distance (Buckland et al. 1993).

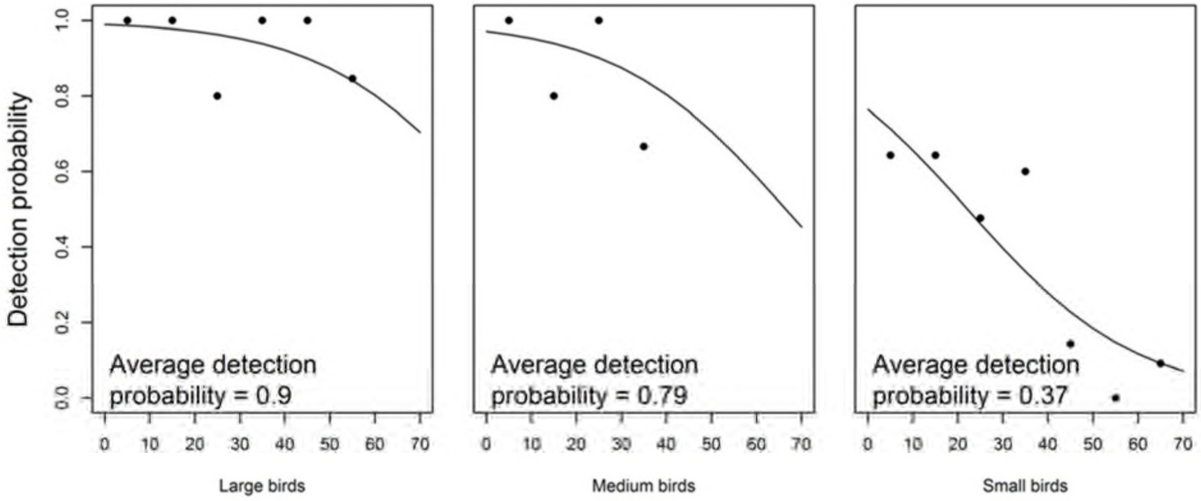

Figure 5. Logistic regression lines were fitted to detection data from the distance sampling trials at Desert Sunlight (HT Harvey 2013c). Data were binned into 10-m intervals prior to analysis. Fitted regression lines and observed proportions are shown. The fit for medium birds may be unreliable due to sparse data, but is probably intermediate between the fits for large and small birds.

Not being able to detect most small to many medium-sized carcasses over a substantial portion of the solar facility would comprise a problematic bias if the probability of carcass occurrence was non-random within arrays (i.e., within sample units). In other words, the bias would create a problem for achieving representative sampling if the probability of mortality due to panel collisions varied in some predictable fashion relative to the distance from array edges, or if there was a tendency for fatalities to be clustered in the interior of the panel areas. Whether or not such conditions may apply to this facility is currently unknown; however, initial post-construction monitoring at another large photovoltaic solar facility in central California has not demonstrated any particular spatial bias in the distribution of fatalities documented there (H.T. Harvey and Associates 2014).

On this basis, fatality sampling will proceed using distance-sampling survey techniques and analytical methods, which include estimating and accounting for distance-related variation in the probability of detection based on the carcass data and bias trial data. In addition, searcher-efficiency trials that are tailored to include evaluating the influence of distance on the probability of detection will be conducted to assess and adjust for the possibility of a spatial bias in the distribution of fatalities. This can be accomplished by comparing the detection function derived from independent searcher-efficiency trials with the detection function derived from the actual fatality data (as it is calculated based on standard distance-sampling techniques). If the two independently derived functions suggest divergent relationships between distance and the probability of detection, the pattern of divergence between them can be used to adjust results of the distance-sampling-based fatality estimate

7.2.4 Temporal Sampling Design

The appropriate frequency of fatality surveys depends on the species of interest and average carcass persistence times (Smallwood 2007, Strickland et al. 2011, USFWS 2012). Large raptors tend to persist and remain detectable for extended periods (weeks to months) due to low scavenging rates and relatively slow decay rates. If only large species were of interest, extended search intervals of 30–45 days might be appropriate; however, smaller birds and bats typically disappear at much faster rates, so shorter search intervals are required to ensure effective documentation of fatality rates among these species.

Publically accessible data from three wind-energy studies in the nearby Mojave Desert region of California and western Arizona provide additional, relevant insight (Chatfield et al. 2009, 2010; Thompson and Bay 2012). These studies recorded average persistence times of 17.5–46.8 days for large birds (average 29.0 days, median 22.6 days) and from 5.6–17.4 days (average 9.9 days, median 6.5 days) for small birds. If the median carcass-persistence time for small and medium birds and bats on the Project site is low a 7-day search interval may be required to effectively document fatality rates for small birds and bats. If, however, median small-bird and bat carcass-persistence rates are greater than 7 days, then a longer search interval may be more appropriate. The initial indications of rapid scavenging by ravens at the Project site suggested that a shorter search interval may be needed to provide precise fatality estimates for small bird and bat carcasses. Later data from Corvus (2014) suggests that there is a period of rapid initial removal, particularly for small and medium carcasses with 50% of carcasses in these size classes removed in 8 and 5 days, respectively. Overall, mean carcass persistence in May and June was greater than 10 days for any size of carcass, and greater than 24 days for large carcasses.

Based on these considerations and preliminary data, and based on the simulation analyses discussed previously, the search interval for fatality monitoring will be variable depending on season (Table 2). Searches will be conducted every 7 days during standard spring and fall migration periods (March 1 – May 31, and September 1 – October 31), and every 21 days during summer and winter (June 1 to August 31, and November 1 to February 28/29). After the first 6 months of fatality monitoring and concurrent carcass-removal trials (see below) have been conducted, the search interval may be adjusted based on estimates of carcass persistence. Some migration for some species may occur outside these periods and this will be considered when evaluating the data regarding timing of mortality for species.

Adjusting fatality counts for carcass removal works best when the search interval remains constant through time (Huso 2010); however, within survey periods, season-specific estimates of carcass persistence can be calculated and incorporated in the overall estimation process when variable search intervals are used in different seasons (Shoenfeld 2004; Huso 2010, 2012; and other estimators all have facility to accommodate season-specific estimates). In addition, survey schedules will ensure that fatality surveys are evenly spaced in time to maximize detection of potential, unusual fatality events (Strickland et al. 2011). For these reasons, a standard schedule for completing the surveys will be developed and followed, such that some surveys will occur during most weeks of the year and all sampling units are surveyed on a regular schedule, as dictated by the season.

7.2.5 Survey and Data Collection Protocols

Fatality surveys will be conducted with the observers striving for a consistent pace/speed and approach, and a uniform search effort throughout the search. Searchers will use binoculars at their discretion to survey for carcasses between each row of panels. The Project has rigorous safety protocols in place that address heat and other safety issues. When a potential carcass is detected, the observer will immediately proceed down the row to confirm the detection and, if valid, fully document and bag it according to standard protocols (see below). Depending on the size and nature of the carcass, the observer will either immediately collect the carcass (smaller, easily collected and transported packages) or flag it for pick-up once the sampling-unit survey is completed (larger, messier, or otherwise complicated collections) or to identify it to species. All carcasses will be stored in freezers on-site until the BLM and FWS determine the ultimate disposition.

All bird and bat injuries and fatalities discovered during, or incidental to, the standard carcass surveys will be documented according to the requirements and standards reflected in the USFWS Avian Injury and Mortality Reporting Form. The form is a reporting requirement of the USFWS Special Utility (SPUT) Permit issued to the Project to authorize the handling of dead or injured birds. In addition, finds will be classified as a fatality according to standards commonly applied in California (Altamont Pass Monitoring Team 2007, CEC and CDFG 2007), which dictate that when only feathers are found, to be classified as a fatality, each find must include a feather spot of at least five tail feathers or two primaries within 5 m (16.4 ft) or less of each other, or a total of 10 feathers. Searchers will make their best attempt to classify feather spots by size according to the sizes or identifying features of the feathers. A separate fatality estimate will be made for feather spots for which size classification is impossible. Digital photographs will be taken to document all incidents, and when possible, plausible cause of death will be indicated on data sheets based on evidence (such as blood or fecal smears on solar panels, burns that may indicate electrocution or blunt trauma that may indicate collisions). All carcasses will be examined and where possible cause of death will be recorded (e.g. burns may indicate electrocution, and blunt trauma may indicate collisions). An avian biologist will make decisions on likely cause of death and this will be reviewed by the Biologist overseeing the program.

All fatalities will be assigned to a size class, a taxonomic family, and an ecological guild and weight categories (e.g., 0-100 grams; 101-999 grams; and 1000+ grams). Species will also be classified as resident, overwintering, or whether they are diurnal or nocturnal migrants (or both). It is necessary to know size classes to appropriately correct for searcher efficiency and scavenging, and information about taxonomic family, ecological guild, and time of day when active are relevant to the specific USFWS and project goals of the monitoring plan.

To ensure accurate documentation of the fatality locations, the observer will record the array number, Global Positioning System (GPS) coordinates in latitude/longitude of the carcass location using a handheld device accurate to ± 3 to 4 m (9.8 to 13.1 ft), and a measurement of the distance from the fatality location to the end of the panel row from which the carcass was detected. When an observer proceeds down panel rows to confirm and document detected fatalities, they may detect other fatalities that they did not observe based on the perimeter-only survey. Including such detections in the fatality estimate will confound estimation of fatality density based on application of standard distance-sampling analytical methodology. Therefore, all such supplementary detections will be classified as “incidental” finds (discussed further below). Carcasses that are found within standardized search areas but incidental to the distance sampling searches can be used as an additional validation of the detection functions: the detection function specifies the distribution of found carcasses, but it also specifies the distribution of missed carcasses, and incidentals should follow the latter distribution.

Data records for each survey will also include: 1) full first and last names of all relevant surveyors in case of future questions; 2) start and stop times for each individual sampling-unit survey; 3) a description of the weather conditions during each search; 4) a standardized description of the current habitat and visibility classes represented within each sampling unit; and 5) a description of any search-area access issues, if relevant. Data collected will also include all appropriate fields contained in the SPUT permit.

All personnel involved in implementing this Plan will be included as sub-permittees under the Project’s USFWS SPUT Permit, issued either to the Project or a consultant authorized by the Project. If the CDFW does not consider coverage under the USFWS SPUT permit sufficient, all personnel implementing this plan will also be covered under any applicable CDFW Scientific

Collecting Permit if provided and issued either to the Project or its consultant. Ideally, the relevant state and federal permits will allow fatalities discovered during the study to be removed from the field, stored on-site in a freezer, and used in searcher-efficiency and carcass-removal bias trials. Necessary exceptions will apply to all special-status species (see below). Otherwise, surveyors will place all discovered carcasses or body parts that are not of a special-status species and are not part of an ongoing bias trial in zip-locked plastic bags, clearly label each bag with the incident number, and deliver the bags for storage in the designated freezer at the Project facility.

4.2.6 Fence Line Monitoring

The perimeter fence is subject to inspections approximately once every 7 days during spring and fall migration, and approximately once every 21 days during winter and summer periods with intervals adjusted as necessary based on the carcass persistence trials. A searcher will drive the areas accessible by vehicle close to the inner perimeter of the fence, scanning for fatalities within an approximate 6-m strip transect centered on the fence. Some sections along the fence cannot be driven close to the fence line. The fence line along the western edge of the Project is drivable but the road is approximately 15 m away from the fence and the road and fence are separated by a drainage ditch. The fence along this section is currently covered with a tan tarp to block and trees and shrubs have been planted to reduce visibility of the project from the west. Additions of vegetation and the tarp likely reduce potential for bird collision with the fence. This section of the fence will be driven to document carcasses, but will not be included in adjusted fatality estimates because detection rates are expected to be low. A separate section of the fence in the southeastern corner of the Project cannot be driven because the eastern edge of the berm that bounded construction ponds is too narrow for a vehicle. In this case, the observer will stop at both north and south ends of the berm and use binoculars to search for carcasses. Finally, the road along a portion of the southwest fence line near the entrance gate is approximately 30 to 50 m from the road and is separated from the fence by an area that has recently undergone vegetation restoration. This area will be eliminated from sampling. Fatality rates estimated for sections of the fence that are sampled will be extrapolated to sections of the fence where the standard monitoring protocol cannot be used. Travel speed will be no greater than 5 miles per hour (8 kilometers per hour) while searching to ensure quality detection, and safety. Personnel conducting fence checks will document bird and bat injuries and fatalities discovered along the inner fence line. Injuries and fatalities along the fence line will be documented in the same manner as used for those discovered during the array carcass surveys, and will be reported to the USFWS and CDFW as part of the same overall reporting process. Searcher efficiency trials will be conducted along the inside of the fence in a similar fashion to the trials at the solar arrays. Carcass removal trials conducted at solar arrays will include areas near the inside of the fence as well.

4.2.7 Power Line Monitoring

Power lines are built to APLIC (2005, 2006, 2012) guidelines; however, there is still a collision risk for many bird species. Consequently, a 50% sample of the Gen-tie Line will be monitored every 7 days during spring and fall migration and approximately every 21 days during summer and winter with intervals adjusted as necessary based on the carcass persistence trials.

Searchers will drive or walk 50% of the Gen-tie Line during each visit, scanning for birds within 15 m from the line. Injuries and fatalities along the Gen-tie Line will be documented in the same manner as used for those discovered during the array carcass surveys, and will be reported to the USFWS and CDFW as part of the same overall reporting process.

Some overhead electrical feeder and distribution power lines are co-located within the solar arrays and these co-located power lines may be searched as part of the regular monitoring schedule at arrays. Fatalities that are determined to have been caused by the power lines (as determined by the nature of injuries) will be reported as such to the USFWS and CDFW as part of the same overall reporting process and included in overall fatality estimates. In addition, portions of the Gen-tie Line are co-located with third-party structures and facilities, including other transmission infrastructure and roadways and, therefore, the source of a particular fatality may not be attributable to the Project's facilities.

4.2.8 Clearance Surveys

Depending on when fatality surveys commence, a one-time clearance survey will be conducted beginning approximately 21 days before the first round of official surveys begins in all areas planned for survey (fence line, gen-tie sample areas and solar arrays). The purpose of this survey will be to clear the survey area of any accumulated carcasses that may be present. The sequence of clearance surveys will mirror the schedule for the first official survey to ensure that the interval between the clearance survey and the first standard survey is the same for all sampling units. This is necessary to ensure that carcasses detected during the first round of surveys represent only fatalities that occurred during a preceding interval equivalent to the search interval that will apply afterward. Carcasses that are missed during the clearance survey will cause an upward (conservative) bias in the fatality estimate. Additionally, some estimators (such as the Huso estimator described above) become biased if carcasses that are not detected during a trial are still available during subsequent trials. This 'bleed through' effect can be ameliorated by including only fresh carcasses in the fatality estimate, where 'fresh' means a carcass that has arrived since the previous search. Carcasses that cannot reliably be aged (probably most carcasses) will be assumed to be fresh; this will cause an upward (conservative) bias in the fatality estimate.

7.3 Bird Rescue

Surveyors will record any injured or rescued birds or bats located during surveys. Birds will be assessed by a qualified biologist to determine if it is appropriate to transport the individual to the nearest permitted rehabilitation facility for proper care, or to release them. Injured raptors will be handled only by experienced personnel and will be taken only to rehabilitation facilities that are permitted to handle raptors; this provision is particularly important for eagles. From the Project site, the closest rehabilitation facilities capable of handling all avian species are:

- Coachella Valley Wild Bird Center, 46500 Van Buren, Indio, California, 92201; Phone: 760-347-2647; Contact: Linda York, Executive Director; Hours of Operation: 9:00am-12:00pm, 7 days a week. http://coachellavalleywildbirdcenter.org/

- The Living Desert Zoo & Gardens, 47900 Portola Avenue, Palm Desert, California, 92260; Phone: 760-346-5694 x8 x1; Contact: Sheila Lindquist, North American Manager; Hours of operation: 8:00am-1:30pm (June-September), 9:00am-5:00pm (October-May), 7 days a week (closed Christmas Day). http://www.livingdesert.org/animals/wildlife-rehabilitation/
- Hope Wildlife Rescue, 18950 Consul Avenue, Corona, CA 92881; Phone: 951-279-3232; Contact: Bill Anderson or Cyndi Floreno; **must call first (this is a CA-licensed rehabilitator working out of a personal residence)**.
- All God's Creatures Wildlife Rescue & Rehabilitation, Chino Hills, CA; Phone: 909-393-1590; Contact: Lori Bayour; http://www.allgodscreatures.net/index.html; no address available, contact by phone.
- International Bird Rescue, Los Angeles Center, San Pedro, CA, 90731; Phone: 310-514-2573; Hours: 8:00am - 5:00pm.
- A list of wildlife rehabilitators maintained by California Department of Fish and Wildlife: http://www.dfg.ca.gov/wildlife/WIL/rehab/facilities.html
- The California Council for Wildlife Rehabilitators: http://www.ccwr.org/resources/rehabilitation-facilities-region-6.html

If stranded, but apparently uninjured, water-associated birds are discovered at any time during surveys, the surveyor will take immediate steps to notify an on-call biologist, and assist with efforts to secure the bird and have it transferred as expediently as possible to Lake Tamarisk for release into the water. Injured water-associated birds may be taken to International Bird Rescue, which specializes in the care and rehabilitation of water-associated birds. If a mass event involving many such birds is observed, the surveyor will immediately notify on-call biologist or other biological personnel working on the site about the details and request their assistance identifying injured versus non-injured birds and transporting injured birds to the nearest rehabilitation facility. International Bird Rescue can also assist with mass stranding events. Rehabilitation facilities should be compensated for the costs associated with each bird put under their care.

If a surveyor discovers a dead individual of a species that is fully protected by the state or federally or state-listed as threatened or endangered, and for which handling is not specifically authorized under the applicable salvage permits, he/she will collect data and photos as for any other fatality, but then flag the carcass to mark its location and leave it in place. If it has been confirmed as a federally listed species under the Endangered Species Act, the surveyor will immediately call a USFWS Office of Law Enforcement special agent to determine the appropriate follow-up action.

7.4 Searcher Efficiency Trials

Estimating searcher-efficiency (distance-related detection functions) is a standard component of the distance-sampling approach. Moreover, because estimating detection functions is applied to all survey data and can be organized to variably adjust in relation to covariates of interest (e.g., season, habitat, and carcass size classes), application of this approach will account for typical factors of interest for fatality studies (CEC and CDFG 2007, Huso 2010, Korner-Nievergelt et al. 2011, USFWS 2012, Smallwood 2013). In this case, independent searcher-efficiency trials per season will be conducted to help assess and adjust for potential spatial bias in the distribution of fatalities among arrays. Separate trials will be conducted to assess detection probability associated with fence and gen-tie line searches.

The desert landscape in which this Project is located generally changes little with the seasons, save for brief periods following winter and spring rains when floods may occur and blooming plants may flourish. A recent meta-analysis involving data from more than 70 wind-energy projects suggested that including habitat visibility class as a predictive variable generally eliminated any otherwise apparent seasonal effects on searcher efficiency (Smallwood 2013). Nevertheless, the supplementary searcher efficiency trials for this Project will be repeated seasonally (winter, spring, summer, and fall) and trials will be organized so that all search personnel participate in bias trials. Placement of trial specimens will be timed to limit the number of trial carcasses placed on the landscape at any one time (minimizing the chance of artificially attracting scavengers or, conversely, scavenger swamping; Smallwood 2007). This approach will also ensure that any new surveyors that join the crew participate in searcher efficiency trials. The trials will also be managed to ensure effective quantification of searcher efficiency in relation to predefined habitat visibility classes (low, medium, and high, if relevant), size classes of birds (small and large), and detection distance.

The bias-trial sample sizes required to produce precise, adjusted fatality estimates are not well established, in part because needs may vary substantially depending on actual project-specific searcher efficiency, carcass removal, and fatality rates. However, using searcher-efficiency trials to help evaluate the efficacy of perimeter-only surveys and the distance-sampling approach used in this investigation will require larger sample sizes to produce a sampling design that effectively accounts for distance as a key covariate of interest. In addition, if growth of new ruderal vegetation, or substrate heterogeneity caused by flood events, is sufficient to create a new visibility class under the arrays, the specimen numbers would need to increase to effectively account for this factor. It will also be necessary to ensure that the estimates of searcher efficiency encompass variation among multiple surveyors. The influence of individual surveyors will not be accounted for in a formal, statistical sense by including “surveyor” as a covariate in the estimation model; however, all surveyors will be tested similarly. Each surveyor will be exposed to multiple test specimens of each size class, and at similar repeated levels if testing in different habitat visibility classes is required. A minimum of 15 carcass samples per small size class, 10 for medium, and 5 for large is anticipated within the fence line, solar array, and gen-tie sampling areas per season. Searcher efficiency will be summarized for each individual searcher but to avoid needlessly inflating the variance of the estimate, individual searcher effects will not be included in the fatality estimation model.

Besides representing birds of different sizes, another important factor to consider in searcher-efficiency and carcass-removal trials is the bird species to use as trial specimens. Ideally, all carcasses used for both searcher-efficiency and carcass-removal trials should reflect the range of species likely to be encountered as fatalities in the Project area (CEC and CDFG 2007). Because obtaining sufficient samples of "natural" carcasses often is difficult, researchers frequently resort to using readily available, non-native surrogate species in bias trails; however, this practice may result in biased results when compared to studies that use only "natural" specimens (Smallwood 2007). For all bias trials, this program will maximize use of representative native or naturalized species authorized by permits, either found during the study or gathered elsewhere, as needed, and from diverse sources where possible, but all trial carcasses will be obtained and deployed in a manner that are consistent with applicable regulatory requirements.

Another factor that influences carcass detectability is how fresh and intact the carcass is (Smallwood 2007, 2013). If multiple pieces of a depredated or scavenged carcass are scattered over a modest area, in some cases the fatality may be more easily detected; however, detectability generally decreases when only remnants of a carcass are present, or when the carcass is aged and degraded. Nevertheless, in contrast to wind-energy projects, there is little expectation that this Project will cause injuries and fatalities that result in dismembered carcasses, so this factor is not expected to influence searcher-efficiency or carcass-removal rates (Smallwood 2013). Therefore, bias trials conducted in this study will involve primarily intact carcasses. The searcher-efficiency trial specimens may range from freshly thawed to partially decayed (i.e., selected, subject to availability, to mimic the range of carcass decay that typically accrues over 7-day periods).

A field supervisor or other technician not involved in the standard surveys will place the trial specimens and will recover any specimens missed by the surveyors. All trial specimens will be placed according to a sampling plan that randomly allocates carcasses of different sizes among survey plots and survey days within the assessment areas, but is stratified to ensure equitable representation of different surveyors, fence line vs. solar arrays vs. gen-tie and seasons. To minimize the possibility of unnecessarily attracting scavengers or, conversely, contributing to scavenger swamping, which could affect ongoing carcass-removal trials (Smallwood 2007, Smallwood et al. 2010), placement of searcher-efficiency trial specimens will be distributed throughout the year (appropriately organized to provide season-specific estimates with adequate samples to provide a robust estimate of searcher efficiency), with few specimens placed at any one time. Carcasses will be placed carefully to minimize disturbance of substrates that may bias carcass detection. Sample size and frequency of trials in the second year may be reduced if the TAG deems appropriate (see section 10.0).

All trial specimens will be inconspicuously marked with a piece of black electrical tape wrapped around one leg, in a manner that allows the surveyor to readily distinguish trial specimens from new fatalities, but without rendering the specimen unnaturally conspicuous (Smallwood 2007, USFWS 2012). To ensure a degree of "natural" placement, carcasses need to be represented by placing between rows of panels, under panels, near i-beams supporting the panels, or in the open. Therefore, carcasses will be tossed towards the designated, randomly chosen placement spot from a distance of three to six m. Documentation of each location will include GPS coordinates, notes about the substrate and carcass placement, and a digital photo of the placement location.

Surveyors will have only one opportunity to discover placed specimens. Any missed specimens will be recovered as quickly as possible after surveys have been completed in a given area, and after the surveyor(s) have become aware of the trial through discovery of one or more specimens. Some researchers have argued for leaving missed specimens in place to enable possible discovery in a subsequent survey and thereby mimic the natural situation in which “bleed-through” is possible (e.g., Smallwood 2013, Warren-Hicks et al. 2013; discussed further below). Although this approach may have merit in some situations, its potential value for this Project is offset by the need to avoid attracting ravens, which represent a threat to desert tortoises living in the area (Ironwood Consulting 2010b).

7.5 Carcass Persistence Trials

The degree to which carcasses persist on the landscape depends on a variety of factors reflecting seasonal variation in landscape/climatic conditions and the scavenger community. The composition and activity patterns of the scavenger community often vary seasonally as birds migrate, new juvenile birds and mammals join the local population, and mammalian scavengers variably hibernate or estivate. Seasonally variable climatic conditions also may contribute to variation in carcass decay and removal rates due to variation in temperatures, solar insolation, wind patterns, and the frequency of flooding events. Therefore, to ensure accurate treatment of this bias factor, carcass-persistence rates will be assessed on a quarterly or at least semi-annual basis during the first year that fatality surveys are conducted (CEC and CDFG 2007, USFWS 2012, Smallwood 2013), and during the second year as needed. It is also imperative that carcass-persistence trials effectively account for the influence of carcass type/size, given that persistence times may vary widely depending on the species and size class involved (Smallwood 2013).

To quantify carcass persistence, 15 small, 10 medium, and 5 large carcasses will be randomly placed and monitored within the solar arrays (including the fence line), and along 50% of the Gen-tie Line each season. A minimum of ½ of the carcasses in the solar arrays will be monitored, using motion-triggered, digital trail cameras (e.g., see Smallwood et al. 2010) while the remaining will be visited on foot, for 30 days or until the carcass has deteriorated to a point where it would no longer qualify as a documentable fatality. Some of the carcasses along the gen-tie line will be monitored with cameras if theft and vandalism concerns can be resolved. For carcasses not set up with cameras, the carcass will be visited once a day for the first 4 days, and then every 3 to 5 days until 30 days is reached. Fake cameras or cameras without bias trial carcasses will also be placed to avoid training ravens to recognize cameras as “feeding stations”. Periodic ground-based checking of carcasses also will occur to guard against misleading indicators of carcass removal, such as wind blowing the carcass out of the camera’s field of view. To minimize potential bias caused by scavenger swamping (Smallwood 2007, Smallwood et al. 2010), carcass-persistence specimens will be distributed across the entire Solar Farm, not just in areas subject to standard surveys, and new specimens will be placed every two to three weeks in small numbers. Sample size and frequency of trials in the second year may be reduced if the TAG deems appropriate.

Trial specimens will include only intact, fresh (i.e., estimated to be no more than one or two days old and not noticeably desiccated) bird carcasses that are either discovered during the study or are acquired from other sources after having been frozen immediately following death. If permits allow, preference will be to use carcasses of species that occur in the area. Surrogates, such as game birds and waterfowl, that are similar in size and appearance to species that occur in the area, will be obtained from commercial sources and used if necessary to meet the required sample sizes. However, domestic waterfowl or gamebirds that are white or brightly colored (e.g. male pheasants) will not be used. Scavenging rates for surrogates may be artificially high, at least when compared to raptors (Smallwood 2007, 2013) and may lead to conservative fatality estimates (i.e., an overestimate) for some taxa/groups.

To reduce possible biases related to leaving scent traces or visual cues that may unnecessarily alert potential scavengers, all carcasses used in carcass-persistence trials will be handled with latex gloves, and handling time will be minimized. All trial specimens will be inconspicuously marked with a small piece of green electrical tape wrapped around a leg to distinguish them from both unmarked fatalities and searcher-efficiency trial specimens.

Upon conclusion of the relevant monitoring period, each trial specimen will be classified into one of the following categories:

Intact: Whole and un-scavenged other than by insects

Scavenged/depredated: Carcass present but incomplete, dismembered, or flesh removed

Feather spot: Carcass scavenged and removed, but sufficient feathers remain to qualify as a fatality, as defined above

Removed: Not enough remains to be considered a fatality during standard surveys, as defined above

7.6 Estimating Adjusted Fatality Rates

The sampling design will enable calculation of fatality estimates adjusted for searcher-efficiency, carcass-removal rates, and proportion of area sampled. The adjustment for searcher efficiency will occur by virtue of applying standard methods for analyzing detection data collected using distance-sampling methods, with the data partitioned by season and standardized carcass size classes.

The fatality estimates will be adjusted for variation in carcass persistence, by applying seasonal and carcass-size-specific correction factors to the fatality estimates that have been adjusted for distance-related variation in the probability of detection.

The analytical approach used to calculate adjusted fatality estimates will be similar to that applied in cases where the fatality estimates are derived from strip transects.

For illustrative purposes, we summarize here the basic formulation of the Huso estimator, the first part of which pertains to fatality estimation for different strata, or groups. Essentially, the smallest group for which fatalities are estimated can be considered a stratum, with stratum *k* representing, for example, a set of similarly sized birds within a defined habitat visibility class. Note that strata should be defined to ensure minimum variance in detection probabilities within individual strata, whereas probabilities may vary considerably among strata (e.g., for small versus large birds, or in habitats of low versus high visibility). Depending on the circumstances, there can be strata based on species groups, size classes, seasons, habitats, and/or infrastructure types (also could conceivably model distance categories as another covariate).

For a particular stratum *k* for a given survey plot and search interval, fatality can be estimated as:

$$\hat{F}_k = \frac{c_k}{g_k},$$

where c_k is the number of observed carcasses and g_k is the probability of detecting a carcass. The detection probability g typically is the product of three variables: the probability of a carcass persisting (r), the probability of a carcass being observed given that it persists (p), and the effective proportion of the interval sampled (v):

$$\hat{g} = \hat{p} * \hat{r} * \hat{v}.$$

The probability of a carcass being observed given that it persists (i.e., searcher efficiency) is estimated as:

$$\hat{p} = \frac{number\_observed}{number\_available},$$

with data for calculating this metric derived from searcher-efficiency trials where known numbers of carcasses are distributed over the search area and carcass detection rates are quantified.

The probability of a carcass persisting is estimated as:

$$\hat{r} = \frac{\bar{t}(1 - e^{-I/\bar{t}})}{I},$$

where $\bar{t}$ is the estimated mean carcass persistence time and I is estimated as:

$$I = \min(I_a, \tilde{I}),$$

where I_a is the minimum actual time between searches and $\tilde{I}$ is the effective search interval, defined as:

$$\tilde{I} = -\log(0.01) \cdot \bar{t}.$$

The effective proportion of the interval sampled is estimated as:

$$\hat{v} = \min(1, \tilde{I} / I_a).$$

For this investigation, the formulation for calculating $\hat{F}_j$ would differ from that outlined above, in that "c_k" would represent the estimated number of fatalities already adjusted for searcher efficiency, based on application of distance-sampling methodology, and then g_k would represent the product of only the estimated carcass persistence (r) and the effective proportion of the interval sampled (v). With this modification, the rest of the formulation would be similar.

For a given plot in search interval j, the adjusted total number of fatalities is calculated as:

$$\hat{F}_j = \sum_{k=1}^{K} \hat{F}_{jk},$$

where $\hat{F}_{jk}$ is the estimated number of fatalities within stratum k of search interval j.

Finally, the estimate of Project-wide total fatalities during a given search interval is estimated as:

$$\hat{F} = \frac{1}{a} \times \left(\sum_{i=1}^{n} \frac{1}{\pi_i} \sum_{j=1}^{J} \hat{F}_{ij} \right),$$

where $\hat{F}_{ij}$ is the number of fatalities on plot i in search interval j, a is the proportion of area that was searched and π_i represents a modified weight associated with an unequal probability sample (Huso 2010), and is the product of the probability of selecting plot i and the proportion of fatalities contained in plot i. The total number of search intervals is J, assuming that there is the same number of search intervals for each plot. In practice, one need not assume that J is constant, but presenting it this way simplifies the notation.

Adjusted fatality estimates for the Solar Farm will be expressed per unit area (e.g., acres and arrays) per year.

7.7 Incidental Mortality Documentation

Once post-construction fatality monitoring begins, all subsequent bird and bat injuries and fatalities detected incidental to the standardized, post-construction monitoring program will be classified as “incidental finds,” documented using similar procedures as are used for specimens discovered during the standardized surveys, and integrated with records from the standardized surveys for summary reporting and evaluation purposes. Incidental finds that occur outside of standard search areas will not be included in calculations of adjusted post-construction fatality estimates, but will be summarized within seasonal and annual reports (discussed below).

From a statistical standpoint, a bias will occur if carcasses that are found in standard search areas but not during standardized surveys are recorded and removed prior to the next search of that array. Per USFWS direction, and to be consistent with the raven management plan, these carcasses will be reported directly to an authorized Biologist. These incidental finds will be documented using the same procedures as those discovered during standardized surveys. Data from incidental finds within standardized search areas will be included in analyses to estimate mortality within the solar arrays to be conservative. Appropriate caveats can be included within the seasonal and annual reports to document the potential magnitude of any biases created by recovering these carcasses.

8.0 MINIMUM CREDENTIALS OF MONITORING PERSONNEL AND TRAINING

The fatality monitoring program will be overseen by an Avian Biologist approved by BLM in consultation with Wildlife agencies that has demonstrated the ability to accurately identify the species of birds and bats potentially impacted by the project. Additional Biologists will be approved by the BLM in consultation with the Wildlife agencies for the purpose of accurately identifying species of birds and bats potentially impacted by the project. The approved biologists will assist with fatality monitoring and will be available to respond to incidents at the Project that require expert assistance (e.g. uncertain species identification, possible listed species, or injuries) within 24 hours. In addition, a biologist (minimum of B.S. in wildlife sciences) will be on-site during days of standardized monitoring.

Monitoring personnel may include solar facility staff. Monitors will be trained in distance-sampling search methodology, correct identification and documentation of carcasses, implementation of carcass removal trials and notification of a rehabilitation center in the event of injured birds or bats. Only staff/technicians that are listed under the SPUT and CDFW Scientific Collecting Permits will be allowed to handle carcasses. Accurate identification of rare, special status species will be emphasized during training. All surveyors will have photo cards to classify specimens and will take photographs of all finds. All data collection will be standardized and the Approved Avian Biologist will decide which to report as survey observations; however, all observations that were not conclusive will be reported.

The trainer, curriculum and training materials for training of non-biologist personnel in monitoring methods will be approved by BLM in consultation with the Wildlife agencies and will be conducted by The Approved Avian Biologist prior to initiation of the study. Training materials may be augmented by wildlife agency input. Components of the training program will include:

- A classroom-based portion with lecture and handout materials, and photographic or specimen-based (if available) species identification;
- A field-based portion that allows trainees the opportunity to practice and receive feedback on conducting carcass searches and trials, identification of species, completing data forms, and following protocols for assessing and assisting injured birds and bats;
- Assessment of learning outcomes for each participant;
- A training log to be updated with each trainee's name and contact information upon successful completion of the course.

The Avian Biologist that will conduct the training will, minimally, have a master's degree in biological sciences, zoology, botany, ecology, or a related field, and at least one year of field experience with avian or bat research or monitoring in the region. All reference material should be maintained and provided to the agencies in the event that there are questions about species identification.

9.0 REPORTING

9.1 USFWS Bird Fatality/Injury Reporting Program

The Project will report all documented bird injuries and fatalities to the USFWS using the required Avian Injury and Mortality Reporting Form that is a reporting requirement of the USFWS SPUT Permit issued to the Project to authorize the handling of dead or injured birds. SPUT reporting will be submitted monthly or in accordance with the terms of the permit. Similar reporting to the CDFW will be accomplished as a condition of any relevant Scientific Collecting Permit that the CDFW may issue to authorize the handling of dead or injured birds under state law.

9.2 Incidental Bird Injury/Fatality Reporting

All injury and fatality incidents discovered outside of the standardized carcass surveys will be documented in the same manner as used for those discovered during the carcass surveys, and will be reported to the USFWS and CDFW as part of the SPUT process. Special status or listed species will also be handled in a way that is consistent with project-specific SPUT permit conditions. Additional details on reporting are found in the Desert Sunlight Wildlife Incident Reporting System (Appendix C).

9.3 Summary Reports

Seasonal electronic summaries of all biological monitoring activities will be submitted to BLM, USFWS, and CDFW throughout the monitoring period. After the fourth quarter of each year of monitoring, a biologist representing the Project will assist the Project in preparing and submitting to the CDFW, BLM, and USFWS an annual report that summarizes dates, durations, and results of all fatality monitoring conducted to date.

To address the specific objectives of the monitoring plan, summary reports will include overall fatality estimates with confidence intervals, and fatality estimates by season. In addition, to the extent possible, fatality rates will be estimated and reported for likely diurnal, and likely nocturnal species, and for ecological guilds of interest (e.g., raptors, water-associated birds, passerines). Summary reports will also include spatial analyses of the data that address whether fatalities are randomly distributed throughout the facility. All raw field notes, field data, photographs, and GIS data will be submitted to the agencies.

10.0 TECHNICAL ADVISORY GROUP AND ADAPTIVE MANAGEMENT

A Technical Advisory Group (TAG) will monitor Project activities, including fatality data, to provide recommendations to the BLM on the need for any adaptive management, including the adoption of avoidance and minimization measures and methods for assessing their effectiveness. The TAG will consist of resource specialists and project biologists from the BLM, USFWS, and CDFW. Persons with scientific expertise may be invited by TAG. In addition, representatives from the Project and the consultants involved in the conduct of the studies will attend and participate in meetings. The TAG will provide advice and recommendations, consistent with the principles below, to the BLM Authorized Officer on developing and implementing effective measures to monitor, avoid, minimize, and mitigate impacts to wildlife species and their habitats related to operations. The BLM Authorized Officer will evaluate any recommendations of the TAG, including discussions with Desert Sunlight concerning new measures or measures that are not completely detailed in this BBCS and make a decision on what measure(s) and monitoring to require for implementation.

A TAG Lead from the Project will be designated for the group whose duties will include disseminating Project data, including data on fatality events, setting up and moderating meetings, reviewing of fatality data, and documenting adaptive management recommendations for the Project. Because the Project occurs on BLM land and BLM is the federal decision-maker, BLM will provide a designated TAG Lead for the Project. It is the TAG Lead’s responsibility to coordinate meetings and involve all team members.

The guiding principles, duties, and responsibilities of the TAG include the following:

- The TAG is only an advisory group.

- Recommendations will be made based on best available science and existing approvals and permits to address specific issues resulting from the Project.
- Recommendations will generally be made by consensus. Where consensus cannot be reached, multiple recommendations will be put forth to the BLM for a final decision.
- Provide sufficient flexibility to adapt as more is learned about the Project as well as strategies to reduce avian impacts if warranted.
- Review results of fatality monitoring.
- In accordance with Mitigation Measure (MM) WIL-5 of the Project's Record of Decision (ROD), if BLM, in consultation with the Wildlife agencies, determine, based on post-construction monitoring, that bird mortality caused by solar facilities is substantial and is having potentially adverse impacts on special-status bird populations, the TAG may recommend adaptive management strategies such as installing additional bird flight diverters, alterations to project components that have been identified as key mortality features, or implementing other appropriate actions to address the relevant findings based on the data.
- Review annual report on status of compliance with mitigation measures and permit conditions and provide recommendations to the BLM Authorized Officer, as necessary.
- Evaluate effectiveness of implemented adaptive management strategies and provide the BLM Authorized Officer with recommendations based on findings.
- The TAG will terminate when the BLM Authorized Officer determines that it is no longer a necessary pathway in reducing avian and bat impacts.

The TAG shall hold the first meeting prior to commencement of post-construction monitoring to review any final details of the monitoring plan. Subsequent meetings will be held following each monitoring season and after the end of each annual monitoring cycle.

After the initial 3-month period, the TAG will review the findings for each monitoring season to determine if adjustments to the monitoring frequency are warranted based on carcass persistence trial results. Desert Sunlight and the agencies will also meet at the end of the second year of monitoring to determine if continued/focused monitoring is warranted. Continued/focused monitoring may be warranted if data indicate that bird mortality caused by solar facilities is substantial and is having potential adverse impacts on special-status bird populations or there are other special circumstances. Such monitoring will be designed to address specific concerns that are identified after review of the data.

Appendix B
Summary of Statistical Simulations for Experimental Design from CVSR

Recent statistical power and precision analyses conducted for another solar project being built roughly 193 km (120 miles) north of the Project site provides some guidance for developing a spatial sampling regime (TerraStat Consulting Group 2013). These simulations were based on projected sampling across an entire 392-MW solar thermal facility, so the results may not accurately reflect the expectation at facilities of different sizes or where sampling is constrained to smaller portions of a large facility; nevertheless, the general guidance they provide is useful. The simulation analyses were parameterized based on several wind-energy studies conducted in the Mojave Desert, and incorporated one of several well-studied mathematical approaches for estimating fatality rates adjusted for proportion of area sampled, search interval, searcher efficiency, and carcass persistence (Shoenfeld 2004). The power analyses assessed the effect of varying the proportion of area sampled from 1% to 30%, using search intervals of 7, 21, and 25 days, and simulating four hypothetical mortality rates (0.5, 1.0, 5.0, and 10 fatalities/MW/year), assuming exponentially distributed carcass removal rates with means of 7.4 or 21.8 days and searcher efficiencies of 0.55 and 0.69 for small and large birds, respectively. The simulation results indicated that the 90% confidence interval for the facility-wide fatality estimate narrowed as the survey area increased, as the search interval decreased, and as the simulated mortality rate increased. The coefficient of variation (CV: $100\% \times$) provides a way to evaluate the relative amount of imprecision in an estimate. The CV is useful because it doesn't depend on the size of the estimate and so can be compared between large and small estimates. Larger values of CV are associated with estimates that are less precise: a CV of 100% indicates an estimate with a standard deviation that is equal to the mean. At all of the simulated mortality rates, and based on a 21-day search interval, the CV for the fatality estimates approached an asymptote once the proportion of area searched reached about 20%. In addition, at the 20% sample level, the CV for the fatality estimates was less than 25% for mortality rates that exceeded 1.0 fatality/MW/year. This level of precision generally is considered adequate for answering the primary questions of interest in such fatality studies (Strickland et al. 2011), and is consistent with guidance from the USFWS Land-Based Wind Energy Guidelines (2012), which states that "the carcass searching protocol should be adequate to answer applicable Tier 4 questions at an appropriate level of precision to make *general* conclusions about the project*, and is not intended to provide highly precise measurements of fatalities*" (p. 45; emphasis added). At the lowest simulated mortality rate, with a 21-day search interval, the coefficient of variation was above 50% at 20% of area sampled, which would be considered a marginal precision level for answering the questions of interest. From a practical standpoint, the importance of precision is diminished if impacts are low. For example, if the take estimate is 0.1 bird per year with 200% CV, this suggests a 90% confidence interval of about (0, 0.4), or a range of less than half a bird per year. On the other hand, if the take estimate is 100 birds per year and the CV is 20%, the 90% confidence interval is (61, 139), or a range of 78 birds per year.

At the lower simulated mortality rates, increasing the proportion of area sampled from 20% to 30% had less impact on the precision compared to decreasing the search interval from 21 days to 7 days. For the two highest simulated mortality rates, however, varying the search interval had less effect on the precision of the adjusted fatality estimates, whether based on 20% or 30% of area sampled, with the CVs remaining between about 8% - 19%. At the 1.0

fatality/MW/year mortality rate with 20% of the area sampled, the CV increased from about 25% with a 7-day search interval to about 40% with a 21-day search interval. At the 0.5 fatalities/MW/year mortality rate with 20% of the area sampled, the relevant change in the CV was from 37% to 57%.

Analysis of data from the CVSR in San Luis Obispo County, California (H.T. Harvey and Associates 2014) corroborates the simulation results. The CVSR is a recently completed 250-MW facility comprising nine discrete photovoltaic solar arrays, which collectively cover approximately 642 ha (1,586 acres) of primarily degraded annual grassland. Beginning in fall 2012, 100% of two arrays were surveyed weekly for bird and bat fatalities using 50-foot transects for large birds and 20-foot transects for bats and small birds. A total of 175 avian fatalities were found during standardized surveys in the two arrays over 10 months. The Huso (2010) estimator was used to estimate the number of fatalities based on documented fatalities adjusted for searcher efficiency and carcass persistence.

Two methods were used to evaluate the potential effects of reduced search area on fatality estimates at CVSR. Spatial clustering of fatalities was evaluated using Global Moran’s I index, which indicates whether objects are clumped, uniform, or random in their spatial distribution (ESRI ArcInfo 10.0, geographic statistical toolbox). Spatial clumping of fatalities within the individual arrays would introduce additional uncertainty into the fatality estimates if sampling covered considerably less than 100% of the survey area. The second method involved resampling the observed fatality data to generate distributions of fatality estimates that would have resulted from searching less than 100% of the study area. Sample sizes varied from one sample unit up to the total number of sample units in the study area (180). (At CVSR, a sample unit was one “tracker unit,” a group of 18 rows of solar panels covering approximately 0.34 ha (0.85 acres); sample units at CVSR were about a quarter the size of the proposed sample units at Desert Sunlight.) For each sample size, 2,000 simulated datasets were generated from the original data. Then, for each simulated dataset, the total number of fatalities for the study area was calculated by scaling the sample count according to the proportion of area represented in the sample. This procedure resulted in a distribution of possible fatality estimates for each level of area sampled. Based on these distributions, means, 90% confidence intervals (CI), and CVs were calculated for each sample size to evaluate the effect of sampling variation on the magnitude and precision of the fatality estimates.

The geospatial analysis indicated that the distribution of fatalities in the two, 100% searched arrays did not differ significantly from a random distribution (H.T. Harvey and Associates 2014). Results of the resampling analysis indicated that the mean fatality estimates and the 90% CIs for those estimates stabilized at about 20% of area sampled (Figure 1). Examined in a different way, the results indicated that the CVs of the sample distributions declined with increasing sample size and that, again beyond about 20% of area sampled, further increases in area sampled resulted in only small increases in precision (Figure 2). Moreover, at the 20% sample level, the CV for the fatality estimates was well below 20%, which is a level of precision that is considered adequate for answering the primary questions of interest in such fatality studies (Strickland et al. 2011, USFWS 2012). With regard to applying these results to other sites, it is important to note that the results may be sensitive to: 1) the relative proportions of large and small birds represented in the fatality sample, which were combined for this analysis; 2) the number and distribution of fatalities across the site; and 3) the influence of variation in searcher efficiency and carcass persistence.

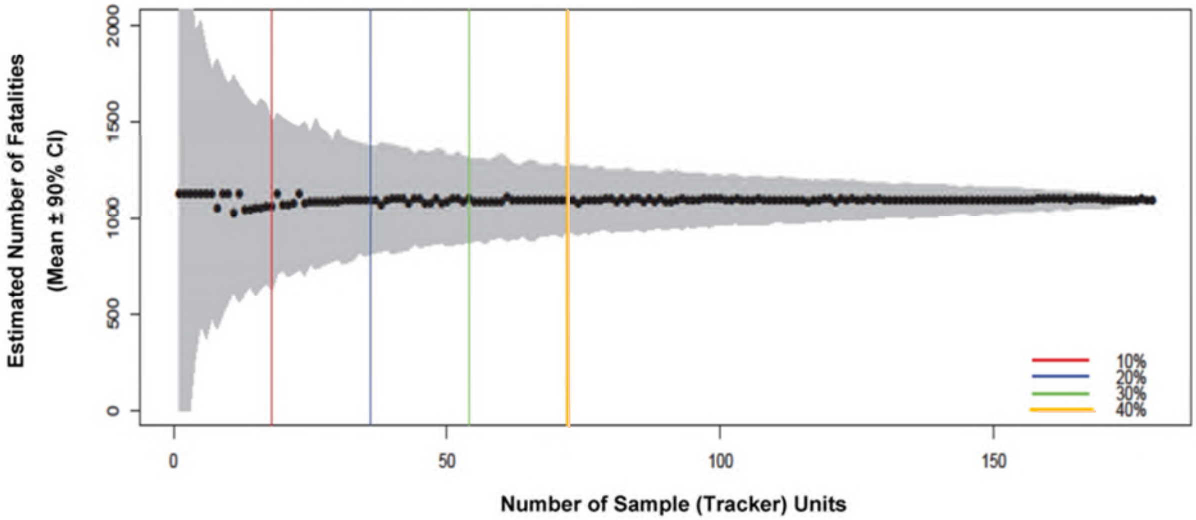

Figure 1. Resampling results from the California Valley Solar Ranch illustrating how the accuracy and precision of fatality estimates and varies with proportion of area sampled.

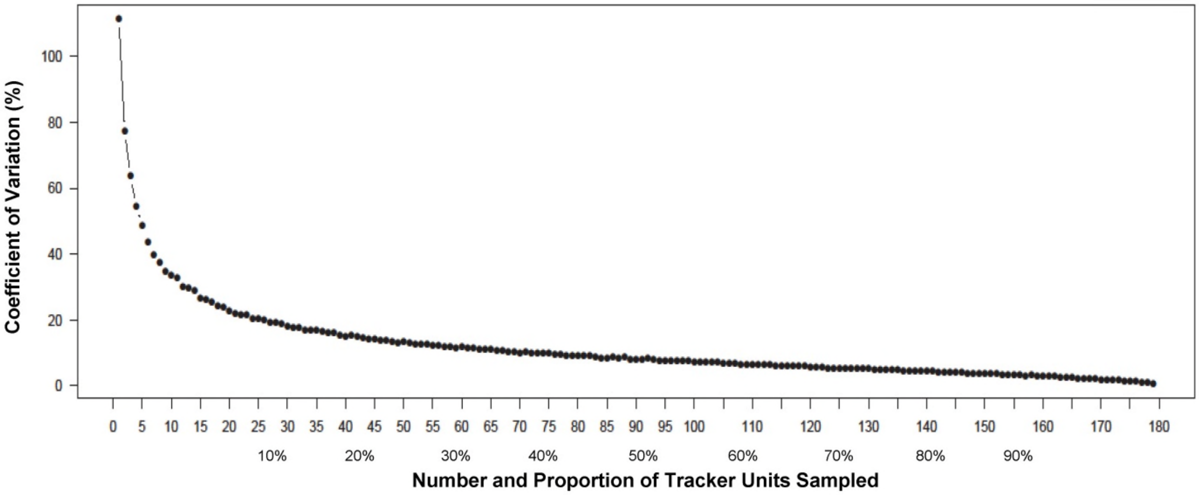

Figure 2. Resampling results from the California Valley Solar Ranch illustrating how the coefficient of variation for fatality estimates varies with proportion of area sampled.

Appendix C
Desert Sunlight Wildlife Incident Reporting System (WIRS)

DESERT SUNLIGHT
WILDLIFE INCIDENT REPORTING SYSTEM (WIRS)

BACKGROUND AND INTRODUCTION

Desert Sunlight will voluntarily implement a wildlife incident response and reporting system. Desert Sunlight will record and report all dead and injured wildlife including but not limited to birds found incidentally in the project areas over the entire life of the project as part of the project operations and monitoring efforts. The purpose of this Wildlife Incident Reporting System (WIRS) is to standardize the actions taken by site personnel in response to wildlife incidents found within project boundaries. The WIRS provides direction for site personnel who may encounter a wildlife incident in an effort to fulfill obligations in reporting wildlife incidents. Wildlife fatalities or injuries found by project personnel or others will be reported and processed following the protocols described in this document.

DESERT SUNLIGHT WIRS POLICY

This WIRS will be active for the life of the solar projects. All employees, contractors and subcontractors of Desert Sunlight have a responsibility to comply with all environmental laws and regulations. Most birds are protected by the federal MBTA, and eagles are further protected by the BGEPA. In addition, the state of California has an Endangered Species Act (CESA). Under the federal statutes, it is illegal to harm, harass, kill, or collect birds that may be found in the solar facility. A summary of these statutes is presented below. It is recognized that other wildlife including bats are generally not protected by federal or state law unless listed as a threatened or endangered species. However, it is the policy of FS to treat all wildlife incidents the same as avian incidents and include them in the WIRS.

It is illegal to collect an injured or dead bird without appropriate federal and state permits. **THE TOUCHING, POSSESSION, TRANSFER, OR TAMPERING WITH ANY WILDLIFE SPECIES (ALIVE OR DEAD) BY DESERT SUNLIGHT EMPLOYEES OR SUBCONTRACTORS IS STRICTLY PROHIBITED UNLESS CONSISTENT WITH PERMITS.** The WIRS is designed to provide a means of recording and collecting data about wildlife species found in the solar facilities to increase the understanding of solar and wildlife interactions. Desert Sunlight maintains an ongoing commitment to investigate wildlife incidents involving company facilities and to work cooperatively with federal and state agencies in an effort to minimize the potential for future bird and wildlife fatalities. The objective of this policy is to insure that the best available information about wildlife incidents found in Desert Sunlight facilities is recorded and the proper authorities are notified. It is the responsibility of Desert Sunlight employees, contractors and subcontractors to report all wildlife incidents as outlined in this WIRS.

APPLICABLE LAWS AND REGULATIONS

Migratory Bird Treaty Act

The Migratory Bird Treaty Act of 1918 (MBTA) (16 USC 703-712) is the cornerstone of migratory bird conservation and protection in the United States. The MBTA implements four treaties that provide for international protection of migratory birds. It is a strict liability statute wherein proof of intent is not an element of a "taking" violation. Wording is clear that most actions resulting in a taking or possession (permanent or temporary) of a protected species can be a violation, regardless of intent.

Specifically, the MBTA states: “Unless and except as permitted by regulations...it shall be unlawful at any time, by any means or in any manner, to pursue, hunt, take, capture, kill, attempt to take, capture or kill, possess…any migratory bird, any part, nest, or egg of any such bird…(The Act) prohibits the taking, killing possession, transportation, and importation of migratory birds, their eggs, parts, and nests, expect when specifically authorized by the Department of the Interior." The word "take" is defined as "to pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to pursue, hunt, shoot, wound, kill, trap capture, or collect."

The MBTA protects 836 species of migratory birds (listed in 50 CFR 10.13), including waterfowl, shorebirds, seabirds, wading birds, raptors, and passerines. Generally, the MBTA protects all birds in the U.S. except upland gamebirds (e.g., pheasant, quail, etc), rock doves (pigeons), European starlings, and English house sparrows. Nearly all birds found at Desert Sunlight are protected under the MBTA.

Bald and Golden Eagle Protection Act

In June 1940, Congress signed into law the Bald and Golden Eagle Protection Act (BGEPA) (16 USC 668-688d) which affords additional protection to the bald and golden eagle. Specifically, the BGEPA states: “Whoever, with the United States or any place subject to the jurisdiction thereof, without being permitted to do so as provided…shall knowingly or with wanton disregard for the consequences of his act take, possess, transport…at any time or in any manner, any bald or golden eagle, alive or dead, or any part, nest or egg thereof shall be fined…that the commission of each taking or other act prohibited by this section, with respect to a bald or golden eagle, shall constitute a separate violation of this section." Penalties for violations of the BGEPA are up to $250,000 and/or 2 years imprisonment for a felony (violations are defined as a felony), with fines doubled for organizations. FS

Endangered Species Act

In 1973, the Endangered Species Act (ESA) (16 USC 1513-1543) was passed to protect endangered and threatened species and to provide a means to conserve their ecosystems. Under the ESA, Federal agencies are directed to utilize their authorities to conserve listed species, as well as "Candidate" species that may be listed in the near future, and make sure that federal agencies' actions do not jeopardize the continued existence of these species. As with the MBTA and the BGEPA, the ESA as amended prohibits the taking of species listed under the act as threatened or endangered.

BLM Sensitive Species

BLM Sensitive Species are species designated by the State Director and includes only those species that are not already federal listed proposed, or candidate species, or State listed because of potential endangerment. BLM's policy is to "ensure that actions authorized, funded, or carried out do not contribute to the need to list any of these species as threatened or endangered."

California Fish and Game Code

Sections 3511, 4700, 5050, and 5515 of the California Fish and Game Code outline protection for fully protected species of mammals, birds, reptiles, amphibians, and fish. Species that are fully protected by these sections may not be taken or possessed at any time. CDFW cannot issue permits or licenses that authorize the "take" of any fully protected species, except under certain circumstances such as scientific research and live capture and relocation of such species pursuant to a permit for the protection of livestock. Furthermore, is the responsibility of the CDFW to maintain viable populations of all native species. To that end, the CDFW has designated certain vertebrate species as Species of Special Concern because declining population levels, limited ranges, and/or continuing threats have made them vulnerable to extinction**.**

DESERT SUNLIGHT WILDLIFE INCIDENT REPORTING

The following procedures are to be followed when Desert Sunlight personnel or subcontractors discover a wildlife fatality or injury while on site. These procedures are intended to be in place for the life of the project and are independent of the post-construction monitoring studies. Prior to the initiation of operations, on-site training will be provided to Desert Sunlight personnel and subcontractors regarding the implementation of this WIRS.

When To Use The WIRS - What Constitutes A Reportable Incident?

For the purposes of this reporting system, *incident* is a general term that refers to any wildlife species, or evidence thereof, that is found dead or injured within the wind project. Note that an incident may include an injured animal and does not necessarily refer only to a carcass or fatality.

An intact carcass, carcass parts, bones, scattered feathers, or an injured wildlife species all represent reportable incidents. Desert Sunlight personnel and subcontractors shall report all such discoveries even if you are uncertain if the carcass or parts are associated with the facility.

> A ***fatality*** is any find where death occurred, such as a carcass, carcass parts, bones, or feather spot (10 or more feathers).
>
> An ***injury*** or injured animal is any wildlife species with an apparent injury, or that exhibits signs of distress to the point where it cannot move under normal means or does not display normal escape or defense behavior.

Prior to assuming a wildlife species is injured, it should be observed to determine if it cannot or does not display normal behaviors. For example, raptors will occasionally walk on the ground, especially if they have captured a prey item. Raptors also "mantle" or hold their wings out and down to cover a prey item. These types of behaviors may make the wings appear broken or the animal injured. Identification of specific behaviors typical to the life cycles and distress behaviors of wildlife will be part of the Desert Sunlight wildlife training program. Always exercise caution before approaching an injured wildlife species. **Under no circumstances are site personnel that are not included in the SPUT permit allowed to handle carcasses or injured animals.**

Note: *Any incident involving a federally or state listed threatened or endangered species, bald eagle, or golden eagle must be reported to USFWS and/or California Department of Fish and Wildlife (CDFW) within 24 hours of identification. See project personnel listing for contact information.*

MATERIALS NEEDED TO REPORT AN INCIDENT

1. A copy of this WIRS

2. A Wildlife Incident Report Form (see Attachment 1)
3. Project Personnel Listing and Contact Information
4. Pencil, Pen
5. Camera
6. Flagging

DESERT SUNLIGHT WILDLIFE INCIDENT REPORTING PROCEDURES

The following procedures apply if the incident involves a **Wildlife Fatality** or **Injured Wildlife Species**:

- **Leave the subject animal in place**. A flag may be used to mark its location for easy finding while the data sheet is being completed. It is recommended that any flagging be marked with the date, time, and initials of the recorder. **DO NOT HANDLE THE CARCASS.**
- **Report** the find to the Site Operations Manager immediately.
- The Site Operations Manager shall complete the following steps:
    - **Photograph** the incident as it was found in the field. Take at least two pictures: a close up shot of the animal as it lays in the field and a broader view of the animal (marked by a flag) with the road, turbines, or other local features in the view. For the close up picture, place an object (e.g., radio, pencil, coin, etc.) next to the carcass for a scale of size.
    - **Prepare a Wildlife Incident Report Form.** The form and associated instructions are presented below.
    - **Report** the find to Desert Sunlight's Environmental Department.

The following procedures apply if the incident involves an **Injured Wildlife Species**:

- **Move** to a distance far enough away that it is not visibly disturbed or uneasy due to your presence. **DO NOT ATTEMPT TO CAPTURE OR HANDLE AN INJURED ANIMAL.**
- **Report** the find immediately to the Operations Site Manager
- The Site Operations Manager shall complete the following steps:
    - **Report** the find to the Environmental Affairs Lead immediately.
    - **Contact** a local rehabilitation center (*see contact list below*) for further instructions on handling and transport/pickup of the injured animal.
    - **Prepare a Wildlife Incident Report Form.** The form and instructions for filling out the form are provided below.

*** Any incident involving a federally or state listed threatened or endangered species or a bald or golden eagle must be reported to the USFWS and/or CDFW within 24 hours of identification. These**

incidents will be reported to the agency verbally by the Operations Manager or Desert Sunlight's Environmental Department.

DESERT SUNLIGHT
WILDLIFE INCIDENT REPORTING FORM

INCIDENT DETAILS

Project Location/Name:

Name of Observer/s:_________________________ Date: ______________ Time: _________

Type of Incident: ☐ Injury ☐ Fatality

Carcass Condition: ☐ Intact Carcass ☐ Partial Carcass ☐ Feathers Only

Age of Remains (days): ☐ 1-2 (fluid filled eyes) ☐ 2-4 (maggots) ☐ 5+ (dried bones/feathers)

Photos Taken: ☐ Yes ☐ No (Take photos of - Birds: beak, legs, feathers, body. Wildlife: face and ears, tail and feet, body)

Who was notified of incident? (see contact list below)____

Comments on Carcass Condition or Behavior of Injured Animal:_______________________________________
____

LOCATION

Where Found: ☐ On Access Road ☐ Solar Array ☐ Under Power Line ☐ Substation

GPS Coordinates: UTM N:_________________ UTM E:_________________ DATUM:__________

Comments on Location:____

IDENTIFICATION

☐ Bird ☐ Bat ☐ Mammal ☐ Other:__________________________

Species (to best of ability):____

Description of Color/Markings:____

Does Animal Resemble a Species of Concern discussed at Training? ☐ Yes ☐ No

Identification Remarks:____
_

(Describe details of - Birds: beak size, color, and shape; leg size, color, and shape; feather color; body size. Bats: color of fur and wings; muzzle long or short, tail attached or extending; ear color and shape); Other Wildlife: color of fur, any markings, and body size.

ENVIRONMENTAL CONDITIONS

Weather (Check all that apply): ☐ Clear ☐ Cloudy ☐ Rain ☐ Dust Storm

Approximate Temperature (F°):_________

Wind: ☐ Calm ☐ Breezy/Gusty ☐ Strong Winds

Habitat where found: ☐ Gravel (access road/turbine pad) ☐ Bare Ground ☐ Wash ☐ Desert scrub

Subject: Bird and Bat Conservation Strategy for the Desert Sunlight Solar Project in Riverside County, California

The U.S. Fish and Wildlife Service (Service) appreciates the continued coordination among the Renewable Energy Action Team (REAT) agencies on project-specific planning, environmental review, and development of compliance plans, including Bird and Bat Conservation Strategies (BBCS). The Bureau of Land Management (BLM) recently approved the BBCS for the Desert Sunlight Solar Project. We have provided substantive comments on several iterations of the draft BBCS that were not incorporated into the accepted version, and would like to highlight the importance of the monitoring program within the adaptive management[1] framework as a means of addressing and evaluating our stated concerns. As we learn more about the relationship between solar facilities and avian impacts, we anticipate the need for further refinement of this and other project-level BBCSs, as monitoring results and changing agency policy may warrant.

Because utility-scale solar development is a relatively nascent industry, systematic monitoring designed to assess the impacts associated with construction and operation of these types of facilities has not been conducted. Consequently, our current scientific understanding of the effects of all aspects of facility operations (e.g., noise, lighting, panels, utility lines, etc.) on bird and bat impacts, such as differential effects on behaviors and mortality rates of resident and migratory species, and changes in population status of those groups, is limited.

---

[1] Adaptive management is an iterative, science-based process that involves: (a) formulating alternative actions to meet measurable objectives; (b) predicting the outcomes of alternatives based on current knowledge; (c) monitoring to test the assumptions underlying those predictions; (d) implementing alternatives; (e), monitoring the results; and (f) using the monitoring results to improve knowledge and adjust actions and objectives accordingly.

The Service will participate in the Technical Advisory Group (TAG) that has been established for this project. Therefore, in preparation for the TAG process, we offer the following key components of the BBCS that will best help the REAT agencies better understand the risks to avian communities and how best to avoid and minimize impacts to migratory birds on this and other solar energy projects. Among other issues, we will ask that the TAG address the topics below as part of their responsibilities.

- The Desert Sunlight Solar Project will be one of the first utility-scale solar projects where systematic mortality monitoring will be conducted. Accordingly, the adaptive management section of the BBCS focuses on the mortality monitoring component of the plan; however, discussions regarding effectiveness monitoring of existing conservation measures and the identification of metrics or thresholds necessary to trigger implementation of additional conservation measures should be articulated in the plan. These types of metrics will be useful in addressing impacts that may not have been accounted for during the permitting process. We believe it will be important for the TAG to consider effectiveness monitoring in the adaptive management process to minimize adverse effects to the extent feasible.

- To our knowledge, distance sampling has never been used for this application (mortality monitoring on wind and solar projects). Due to site-specific conditions (obstructed visibility inherent to the project panel configuration), 100 percent of the proposed search area may not be adequately observed. Therefore, additional survey area may be needed to meet the stated objective to survey 30 percent of the solar field. The TAG should evaluate the results after each monitoring season and make recommendations to BLM to modify the methodology, if warranted.

- The BBCS establishes mixed monitoring intervals (7 and 21 days) for different seasons. Longer monitoring intervals are not supported by the Corvus carcass persistence trials performed on the Desert Sunlight site to date, HT Harvey's detectability study, and much of the available literature from the Mojave region. Longer survey intervals could introduce a bias toward larger bodied species, with medium and smaller sized species being under-represented. This bias could be further complicated by sampling only a subset of the fall and spring migration periods. Consequently, these intervals coupled with the distance sampling method as proposed, could result in statistically significant under-sampling, which cannot be corrected for using estimators. We suggest the TAG evaluate the methods and results in accordance with an agreed upon schedule as discussed below.

- There are over 400 species of resident and migratory birds known to occur in this region (Rosenberg et al. 1991, Patten et al. 2003). The migration periods specified in the BBCS are inadequate to cover the suite of species that have been documented in the area. We will work within the framework of the TAG to review a subset of avian species migratory patterns and make recommendations to adjust the migration monitoring periods, as appropriate, to avoid bias where possible, in the mortality monitoring results.

- Mortalities of rare species have been documented at this and other solar facilities in the California desert. Currently, the BBCS includes systematic monitoring of 30 percent of the solar field; however, this level of survey effort may not be sufficient to detect rare mortality events of uncommon and/or listed species, such as Yuma Ridgway's rail. New modeling tools, such as the Evidence of Absence tool (Huso *et al.* in press), have recently become available and can be used to inform what level of monitoring will be needed to increase the level of confidence that a rare mortality event has not occurred during the monitoring period. We recommend that the TAG assess whether the use of this tool should be used to inform future monitoring efforts.

- The BBCS allows the use of monitoring personnel who do not have academic ornithological and field ecology/biology background or personnel with limited experience in the desert Southwest. While training will be conducted, locating carcasses can be quite difficult, especially for surveyors unfamiliar with scientific principles, and measurements for distance sampling will need to be precise to support a robust analysis. An assessment of searcher efficiency rates and a complete description of methods [i.e., the number, size (weight), and species of trial carcasses used, exact time and location of carcass placement, surveyor detectability thresholds, etc.] should be reviewed periodically by the TAG to determine if modifications are warranted.

  Accurate identification of species is critical to understanding which species/taxa may be at risk from the project. We appreciate that an Authorized Avian Biologist will be available to ensure proper identification of carcasses and implementation of collection protocols and that a biologist will be on-site during monitoring periods to provide oversight. However, for carcasses and feathers that the Authorized Avian Biologist cannot identify, we would like to establish a process to have these items identified by a federally permitted natural history museum, ornithological research institution, or public wildlife forensic laboratory approved by the Service.

- As part of our efforts to gain a better understanding of cumulative impacts associated with solar projects throughout the desert region, biological samples from bird carcasses need to be collected. Identification of affected sub-populations of priority species is needed to help determine the significance of demographic impacts. Determination of the sub-species and regional populations affected require the collection of morphometric, genetic, and isotope data from collected carcasses (including those currently in storage on the project site).

One of the primary functions of an effective mortality monitoring program is to obtain the data necessary for the TAG to make informed decisions on the implementation and/or modification of conservation actions needed to reduce the impacts of mortality. Data are also needed to assist the TAG in determining the effectiveness of those conservation actions once they are adopted. We recommend that the TAG review the site-specific avoidance and minimization measures implemented to date by the project proponent, and assess whether effectiveness monitoring data could be collected to determine the utility of these and any future conservation actions.

The BBCS for Desert Sunlight states that the TAG meets subsequent to each monitoring season to review results of the carcass persistence, searcher efficiency, and mortality monitoring surveys. Seasonal meetings will allow the TAG to evaluate the concerns listed above and recommend any necessary adjustments to the monitoring methods prior to the next seasonal survey, if warranted and the meeting schedules allow.

We also recommend that an annual comprehensive report that includes mortality estimates for all birds and key taxa identified by the TAG, an analysis of meteorological data, taxa-specific migration information that may affect avian presence on and around the project site during the monitoring period, be submitted to the TAG after each full year of monitoring. The report should analyze the assumptions associated with the protocol, monitoring methods employed, and results that inform any conclusions. Based on a review of the report, the TAG may recommend continuation of the current protocol or recommend modifications to the methods to better achieve the monitoring goals and objectives.

We look forward to participating in the TAG and working together to develop and implement a meaningful adaptive management strategy that will facilitate conservation of our shared trust resources. If you have any questions regarding these comments or our recommendations, please contact Thomas Dietsch in our Division of Migratory Birds at thomas_dietsch@fws.gov; (760) 431-9440, extension 214 or Jody Fraser in the Palm Springs Fish and Wildlife Office at jody_fraser@fws.gov; (760) 322-2070, extension 207.

Re: Notification of Long-eared Owl Fatality

In accordance with the Conditional Use Permit (CUP) and Tract Map DRC2008-00009 & SUB2010-00060/Topaz Conditions of Approval (COA) 43l, this memorandum serves as formal written notification of the finding of a dead special status wildlife species at the Topaz Solar Farms project.

On June 2, 2015 during Avian Fatality Surveys an Althouse and Meade, Inc. biologist detected a group of feathers from an owl along a medium voltage collection line transect in Block 11 (Figure 1 attached). On June 8 the feathers were confirmed to be from a long-eared owl (*Asio otus*), a California Species of Special Concern. The feathers included primaries, secondaries, and coverts from a right wing. The primaries were in a clump, attached at the base by flesh. Condition and location of the wing, and damage to the base of the shafts, is consistent with raptor predation, but actual cause of death is unknown.

A long eared owl nest located in trees at the Carissa Elementary School is the only known nest location in the vicinity of Topaz Solar Farms. At least three fledglings were observed in 2015 at this nest.

EXECUTIVE SUMMARY

Avian and bat monitoring surveys were conducted from February 10 to May 31, 2015 (the reporting period) at Desert Sunlight Solar Farm Project (Project) in accordance with the Project's Bird and Bat Conservation Strategy (BBCS). Specifically, standardized carcass searches, searcher efficiency trials, and carcass persistence trials were conducted. This report represents the first seasonal report for the first year of monitoring, and summarizes monitoring methods and results for those surveys based on the procedures and requirements specified in the BBCS.

The spring season at the Project is defined as March 01 to May 31. Included in this report are data from the spring season and data collected from February 10-28. Standardized carcass searches were conducted 1) in the solar field, consisting of a random stratified 29.5% sample of solar photovoltaic (PV) panels, 2) along inner portions of the fenceline, resulting in 74.4% of the length of the perimeter fence, and 3) along 47.9% of the total length of generation-tie (gen-tie) line from the Project fence to the Red Bluff Substation located south of Interstate 10 (I-10). The two searches conducted during February had an interval of approximately 16 days, and searches conducted within the spring season had intervals of approximately seven days.

Comentado [FWS1]: Pre-spring survey data are not meaningful and should probably be excluded. Please describe how these data were or were not incorporated into estimates.

All bird and bat fatalities and injuries that were discovered by observers, referred to as "detections" in this report, including those found incidentally and during standardized carcass searches, were documented. During the reporting period, 25 avian detections (including 1 injured bird) were made, while there were no detections of bats.

According to specifications of the BBCS, avian detections were categorized by likely diurnal or nocturnal migration behavior, ecological guild (e.g., raptors, songbirds, etc.), facility component, and suspected cause of death. These standardized carcass search results, along with searcher efficiency and carcass persistence rates from bias trials conducted on site, were applied to a fatality estimator model (Huso 2010) to provide a preliminary estimate of the number of fatalities that occurred at the Project during the reporting period adjusted for sources of bias. The estimate is considered preliminary because the annual report may pool information from bias trials and other data across seasons which could affect seasonal estimates.

Comentado [FWS2]: Please record and report the time of the surveys. This will help determine if the surveys can be used to predict nocturnal vs. diurnal mig behavior.

During the reporting period, carcass persistence was influenced by carcass size and Project component. Small carcasses (0-100 g) in the arrays and along the fence (combined) had a 0.54 probability (90% confidence interval [CI]: 0.47 – 0.61) of persisting through the 7-day search interval, medium carcasses (101 – 999 g) had a 0.82 (90% CI: 0.69 – 0.92) probability, and large carcasses (1000+ g) had a 0.94 (90% CI: 0.88 – 0.98) probability. Mean removal time within the arrays for small, medium, and large carcasses was 5.7, 29.8, and 126.8 days, respectively. Along overhead lines, probability of persistence for small, medium, and large carcasses were 0.29, 0.71, and 0.72, respectively; mean removal time for small, medium, and large carcasses was 2.0, 13.7, and 14.7 days, respectively. Within the solar arrays, searcher efficiency was influenced by carcass size: 60.0% for small birds, 87.2% for medium birds, and

Comentado [FWS3]: Please include median times and/or a curve showing # remaining over time.

97.3% for large birds. Along the fence, searcher efficiency ranged from 79.3% to 100% depending on carcass size class. Along overhead lines, searcher efficiency ranged from 53.9% to 87.8%.

Using the Huso (2010) fatality estimator model, during the spring period 2015, there were an estimated total 111 fatalities (90% CI: 58 - 193) at the Project. Of these, 49 fatalities (44.1%; 90% CI: 19 – 86) were estimated for the solar arrays, 2 fatalities (1.8%; 90% CI: 2 – 4) were estimated for the fence, and 60 fatalities (54.1%; 90% CI: 16 – 132) were estimated for the overhead lines (gen-tie and medium voltage overhead lines combined). During spring 2015, there were an estimated 0.02 carcasses per acre (49 estimated carcasses/2,585 acres) and an estimated 0.09 carcasses per nameplate MW (49 estimated carcasses/ 550 MW) within the solar field.

LIST OF APPENDICES

1.0 INTRODUCTION

1.1 Project Background

Desert Sunlight 250, LLC and Desert Sunlight 300, LLC (collectively, Desert Sunlight) constructed and operates the Desert Sunlight Solar Farm Project (referred to in this report as "Project"), which consists of two main components: 1) a 550-megawatt (MW) photovoltaic (PV) generating facility; and 2) a 220-kilovolt (kV) generation interconnection (gen-tie) line. The Project comprises approximately 1,700 hectares (ha; 4,200 acres) of land administered by the Bureau of Land Management (BLM) six miles north of Desert Center in Riverside County, California (Figure 1).

1.2 Monitoring Plan Overview and Goals

A Bird and Bat Conservation Strategy (2014; “BBCS”) was prepared by the Project proponent in collaboration with the U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), (BLM) to guide comprehensive monitoring of impacts to birds and bats associated with operation of the Project. Final agency approval of the BBCS occurred in December 2014.

The BBCS details post-construction monitoring to be conducted and the data analysis and reporting processes that will be implemented by Desert Sunlight in collaboration with the USFWS, CDFW, and BLM. As identified in the BBCS, they are:

1. Estimate overall annual avian fatality rate and species composition associated with the Project infrastructure. This estimate will include mortality associated with solar arrays, overhead lines including the gen-tie line, perimeter fence and other features of the Project that may result in injury and fatality.
2. Determine whether there are spatial and temporal/seasonal patterns of mortality associated with project infrastructure (e.g., different fatality rates near panels on the edge of the arrays vs. the interior area of the arrays).
3. Provide information that will assist the BLM in consultation with the USFWS in understanding which species and potentially which regional populations are at risk.
4. Collect data in such a way that the BLM in consultation with the USFWS may make comparisons with other solar sites.

Figure 1. Desert Sunlight Solar Farm Project vicinity map, Riverside County, California.

1.3 Purpose of This Report

This report represents the first seasonal report for the first year of monitoring summarizing monitoring methods and results for avian and bat fatalities and injuries based on the procedures and requirements specified in the approved BBCS. This report covers the period February 10 to February 28, 2015, as well as the 2015 spring season, which includes the period from March 01 to May 31, 2015. All bird and bat fatalities and injuries that were discovered by observers are referred to as “detections” in this report. As stated in the approved BBCS, this seasonal report includes the observed detections for likely diurnal, and likely nocturnal species, and for ecological guilds of interest (e.g., raptors, water-associated birds, passerines), for each of the facility types and suspected causes of death. Species composition of detections and the results of the bias trials are also reported. This report presents information related to the spatial distribution of detections, but no formal statistical analysis of the spatial distribution of carcasses will be conducted until the end of the monitoring year, given the limited data presently available.

2.0 METHODS

The BBCS describes the methods by which monitoring and certain analyses, including compilation of the overall fatality estimate, will occur. Below is an abridged description (see BBCS for detailed methods).

2.1 Standardized Carcass Searches

This section describes areas surveyed, the timing and frequency of searches, and the methods by which standardized searches were conducted to identify dead/injured birds and bats at the Project. Dead or injured birds and bats are called detections in this report to provide consistency in naming. This section also describes the methods for conducting carcass removal and searcher efficiency trials; how data were reported and analyzed; and the methods for producing fatality estimates for the Project.

2.1.1 *Areas Surveyed*

Standardized carcass searches were conducted at sampling units, which include the solar arrays; the "fenceline" defined as the perimeter fence for the Project (Table 1, Figure 2); and the gen-tie line (from the Project fence to the Red Bluff Substation on the south side of I-10; Table 1, Figure 3). Some overhead lines co-occur with solar arrays (medium voltage overhead lines [MVOH]). The MVOH were part of standardized carcass searches to the extent that they co-occured with solar arrays included in the sample. Table 1 provides the total area of each component as well as the percent of each component that was searched.

Table 1. Areas included in standardized carcass searches at the Desert Sunlight Solar Farm Project during spring 2015 (including February).

Project Component	Total Size	Units	% of Component Searched
Solar arrays	1045.9	Hectares	28.2[1]
Solar arrays	1045.9	Hectares	1.3[2]
Solar arrays	1045.9	Hectares	1.3[3]
Fence	16.7	Kilometers	99%[4]
Gen-tie line	19.2	Kilometers	47.9[5]

[1] Percent area that was searched continuously since monitoring commenced in February 2015. Slightly less than 30% total (including areas affected by the tornado) because of unequal size arrays.

[2] Percent that was searched before the April 21, 2015 tornado but not after.

[3] Percent that was searched after the tornado but not before.

[4] 74.4% of the fence is fully accessible and surveyed following the standard protocol, while approximately 25% of the fence is surveyed from a distance. A very short segment near the gate is not sampled due to restoration activities

[5] 52.1% of gen-tie will be sampled in 2016.

Comentado [FWS4]: Please describe how detectability is being handled for the 25% being surveyed from a distance.

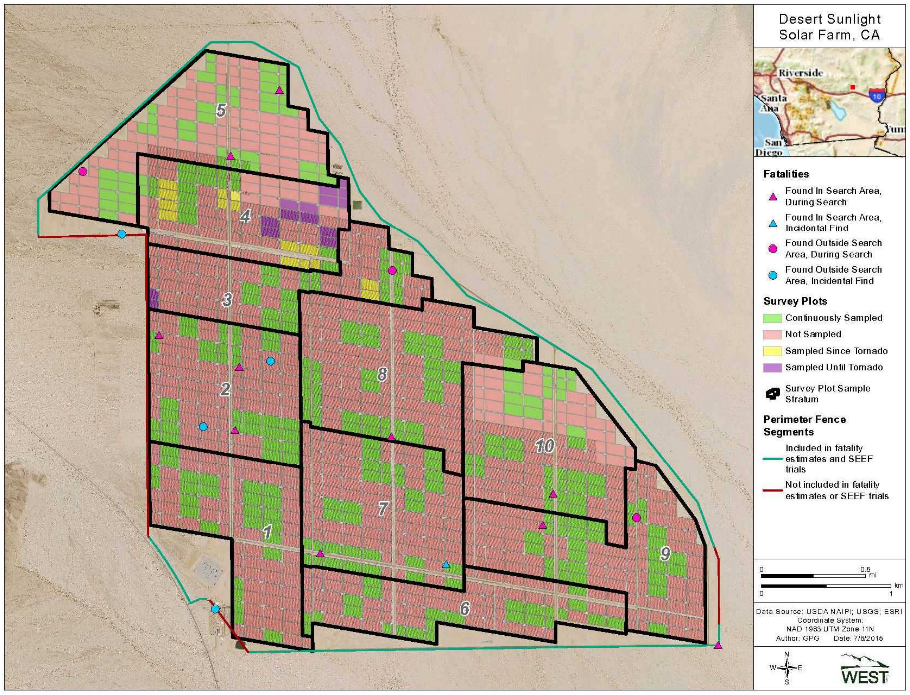

Figure 2. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance) at the solar field, fence, and overhead lines within the fence at Desert Sunlight Solar Farm Project during spring 2015 (including February). Because of the presence of medium voltage overhead lines within the solar arrays, some detections within the arrays were assigned to overhead lines.

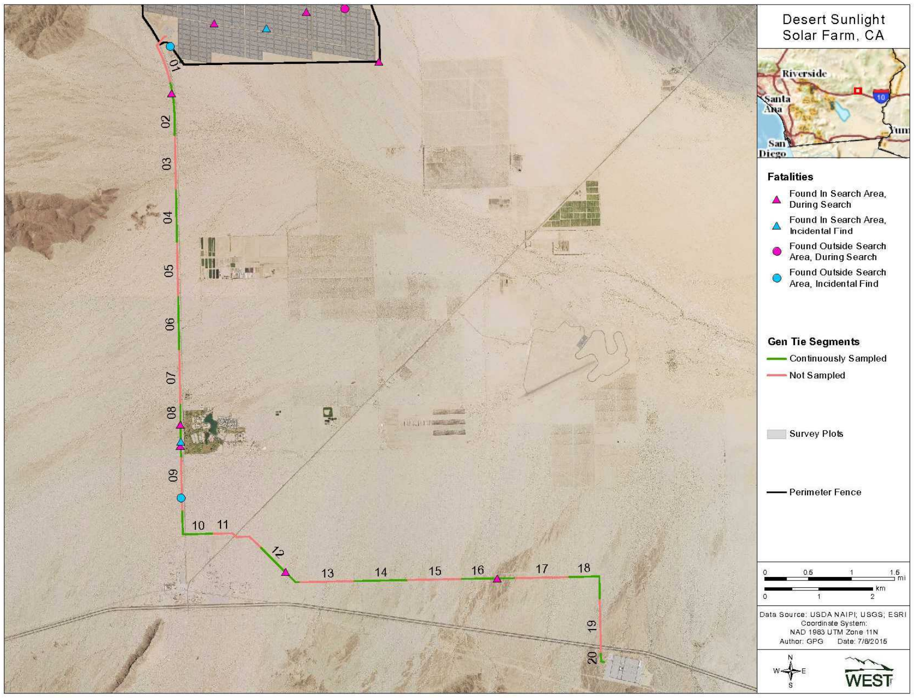

Figure 3. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance activities) along the generation tie line at the Desert Sunlight Solar Farm Project during spring 2015 (including February). Detailed maps of detections along the line are presented in Appendix A.

To ensure a balanced distribution of sample units in the solar field (defined as the collection of all photovoltaic [PV] solar panels), the entire field was divided into ten strata, and individual sampling units were randomly selected within each stratum to compose an approximately 30% sample. The solar field consists of arrays of solar panels (referred to as a solar array). This sampling design ensures that units included in the sample were not spatially clumped within the solar field.

2.1.1 *Search Frequency and Timing*

Standardized searches began February 10, 2015 (during the winter season outlined in the BBCS). The spring survey season includes the period from March 01 through May 31, 2015. All project components included in standardized searches were surveyed 14 times from February 10 to May 31, 2015 (twice in February and 12 times during spring).

The average search interval for all Project components included in standardized carcass searches during February was 16.1 days (median 15 days), and during spring was 7.1 days (median 7 days). Slight variation in search interval was anticipated due to weather and logistical delays. On April 21, 2015, the Project was struck by a tornado. The tornado damaged some of the sampling units, and resulted in limited access that ultimately lasted longer than initially expected. Thus, 142 sample units (128 arrays, fence, and gen-tie combined) were visited 14 times continuously and without interruption during the reporting period (two times in February and 12 times in spring). Six arrays were visited seven times before the tornado occurred; 3 weeks elapsed before the six damaged arrays were replaced with undamaged arrays. Five of the replacement arrays were visited twice and one was visited once.

Comentado [FWS5]: Based on persistence trials?

I suggest putting the carcass and searcher efficiency trials first since they dictate the timing of the standardized carcass searches.

Comentado [FWS6]: This is not clear. Please clarify how sampling was affected by the damage from the tornado.

Further, articulate what was done to replace the arrays that were damaged in the sampling scheme.

2.1.2 *Search Methods*

Standardized carcass searches were performed by BLM-approved biologists, in accordance with methods outlined in the BBCS.

Within the solar field, arrays of solar panels were surveyed by observers traveling on foot. A distance sampling approach was used, whereby biologists slowly walked a transect line along the ends of rows of solar panels in a direction perpendicular to the rows, searching ahead and to the side within the array for bird and bat detections. Biologists scanned out to a maximum perpendicular distance of approximately 70 m from the transect. Biologists carried binoculars to allow them to verify the presence of a detection versus rocks or vegetation. Once a detection was confirmed, the distance of the detection to the transect line was estimated using laser range finders. Each array included in the sample was searched by observers walking two transects – one on the west side and one on the east side of the array with observers looking toward the center of the array.

Comentado [FWS7]: Was the carcass then processed and removed? Please clarify the carcass processing procedure.

Most (74.4%) of the length of fenceline (approximately 10 miles) was searched from a vehicle using the standard protocol (Figure 2). Biologists searched a 6-m wide strip transect centered on the fence from the inner perimeter. Travel speed was below five miles per hour (mph) while searching. Some sections along the fence cannot be driven close to the fence line. The fence line along the western edge of the Project is drivable but the road is approximately 15 m away from the fence and the road and fence are separated by a drainage ditch. The fence along this section is covered with a tan tarp to block and trees and shrubs have been planted to reduce visibility of the project from the west. Additions of vegetation and the tarp likely reduce potential for bird collision with the fence. This section of the fence was driven to document carcasses, but detections along this portion of the fence are not included in adjusted fatality estimates because detection rates are likely very low. A separate section of the fence in the southeastern corner of the Project cannot be driven because the eastern edge of the berm that bounded construction ponds is too narrow for a vehicle. Along this portion of the fence, the observer stopped at both north and south ends of the berm and used binoculars to search for carcasses. Finally, the road along a portion of the southwest fence line near the entrance gate is approximately 30 to 50 m from the road and is separated from the fence by an area that has recently undergone vegetation restoration. This area was eliminated from sampling. Fatality rates estimated for

Comentado [FWS8]: Please describe how this is this accounted for in the overall estimates.

Comentado [FWS9]: Again, please describe how this was accounted for in the estimates.

sections of the fence that were sampled were extrapolated to sections of the fence where the standard monitoring protocol was not used.

Comentado [FWS10]: This doesn't seem valid, given the site differences in these segments of the fences.

The gen-tie line was searched using a 30-m wide strip transect (i.e., 15 m of ground on either side of the overhead line). Sample units along the gen-tie line were chosen by dividing the total length of line from the Project fence south to the Red Bluff Substation just south of I-10 into 1-km segments. Thus, a 47.9% sample of the total length of the line was searched (Figure 3). Biologists slowly walked every other 1-km segment of the line, meandering the width of the strip transect, scanning for dead or injured birds or bats within 15 m (49.2 ft) of the overhead line.

For each detection, a suspected cause of death or injury was assigned based on available evidence and proximity of a detection to Project infrastructure. Detections that had evidence of scavenging were assigned as “unknown” because it cannot be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) had a suspected cause of death attributed to the respective Project component. However, it should be noted that there is substantial uncertainty associated with cause of death assignments because no events were directly observed.

Comentado [FWS11]: The Servicde disagrees with this assumption. If it's under the line, the better assumption is that it was caused by the line and a scavenger subsequently discovered the carcass.

2.2 Carcass Persistence Trials

Carcass persistence trials were conducted for the truncated winter season and throughout the spring period. Carcasses from three size classes (small [0-100 g], medium [101-999], and large [1000+ g]) were used for trials. The small size class comprised house sparrows (*Passer domesticus*) and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons (*Columba livia*), and the large size class comprised hen mallard (*Anas platyrhynchos*) and hen ring-necked pheasant (*Phasianus colchicus*).

2.2.1 *Carcass Persistence Data Collection*

To quantify carcass persistence rates, 15 small, 10 medium, and 5 large carcasses were randomly placed and monitored along the gen-tie line during spring 2015. Within the solar arrays and along the perimeter fence, the same numbers of small and medium carcasses were placed, along with 10 large carcasses, for a total of 65 carcass persistence trials at Desert Sunlight during the spring season. Thirty-five carcasses within the Project fence (within solar arrays and along the fence) were monitored using motion-triggered digital trail cameras, while the remaining carcasses were visited on foot, for 30 days or until the carcass had deteriorated to a condition at which it would no longer qualify as a documentable fatality. No carcasses along the gen-tie line were monitored with cameras because of theft and vandalism concerns. Carcasses without trail cameras were visited and photographed once per day for the first four days, and then every three to five days until the end of the monitoring period. To avoid training scavengers to recognize cameras as “feeding stations”, trail cameras were installed five days before specimens were placed, and two fake cameras without bias trial carcasses were also placed within the Project fence and periodically moved to new locations within the fence. Periodic ground-based checking of carcasses with trail cameras also occured to guard against misleading indicators of carcass removal, such as wind blowing the carcass out of the camera’s

Comentado [FWS12]: This number of carcasses is extremely low. Did you do a power analysis?

field of view. To minimize potential bias caused by scavenger swamping (Smallwood 2007, Smallwood et al. 2010), carcass-persistence specimens were distributed across the entire Project, not just in areas subject to standard searches, and trials were initiated in small numbers on six different dates throughout the spring season.

Comentado [FWS13]: With such a low number of carcasses this is unlikely to be a problem.

In February, 15 (*n* = 7 small, 5 medium, and 3 large) carcass persistence trials were placed in the solar arrays and along the Project fence, and 15 trials (*n* = 8 small, 5 medium, and 2 large) were placed along the gen-tie line. Eight carcasses within the arrays and fence were monitored with trial cameras, and four fake cameras were placed within the arrays and along the fence. Carcass persistence trials were initiated on two different dates in February.

Comentado [FWS14]: Does this mean n=15 was put out twice for the Feb trials? Please clarify. Also, are the gen-tie carcasses outside the project fence? If so, there seem to be two difference scavenger communities being tested.

2.2.2 *Estimating Carcass Persistence Times*

Measurements of carcass persistence rates were subject to censoring. In this context, censoring refers to the instance when a value (e.g. days a carcass is present before being removed) may not be known exactly, but is known to be within a finite range. For example, suppose a carcass was checked on day 7 and was present, and was checked again on day 10, but was found to be missing. The exact time until removal is unknown; however, it is known that the carcass was available to be found for between 7 and 10 days. This carcass would be considered "interval censored". Similarly, if a carcass lasts the entire 30-day trial period, that carcass is "right censored"— it is known that the carcass lasted at least 30 days, but it may have persisted longer.

Comentado [FWS15]: Please describe the interval that carcasses were checked. Is there a reason that they are not checked daily, particularly during the first week?

Comentado [FWS16]: This does not seem true. If the carcass is not there on day 10, they it has been removed before that and would not be available during some portion of the interval. Please clarify how this uncertainty affects the analysis. There should probably be a convention for determining the removal data (i.e., the mid-point). In general, the interval should be kept as short as possible.

Comentado [FWS17]: How does "censored" status affect the analysis?

There were four distributions implemented in survival models used to estimate the probability a carcass is unscavenged and available to be found at the end of the search interval (*r*): exponential, Weibull, loglogistic, and lognormal. These four distributions exhibit varying degrees of flexibility in order to model a wide variety of distributions of persistence time. Akaike's Information Criterion adjusted for sample size (AICc; Akaike 1973) was used to rank the fit of each survival model with combinations of the covariates carcass size, location, and visibility, to observed carcass persistence data.

2.3 Searcher Efficiency Trials

Searcher efficiency trials were conducted throughout the spring period (including February). Carcasses from three size classes (small, medium, and large) were used for trials. The small size class comprised house sparrows and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons, and the large size class comprised hen mallards and hen ring-necked pheasants.

2.3.1 *Searcher Efficiency Data Collection*

Training of biologists on the Project-specific protocol and early assessments of habitat conditions at the Project site suggested that the amount of cobble present in the soil may be an important factor influencing searcher efficiency. To satisfy requirements regarding consideration of visibility class per the BBCS and address the influence of cobble cover on searcher efficiency, sample units in the solar arrays and along the gen-tie were stratified by cobble cover and assigned to one of two classes (<15% and >15% cobble cover). Classes were determined by making ocular estimates of cobble cover at each sample unit and then evaluating the frequency histogram of sample units across the range of estimated cobble cover (Figure 4). A natural break point was identified at 15% cobble cover, so the same value was chosen as the break point that defined the two strata. In the solar arrays, one set of searcher efficiency trials (*n* = 15 small birds, 10 medium birds, and 5 large birds) was conducted in each strata. Similarly, searcher efficiency trials along the gen-tie occurred in two visibility strata (easy: ≥90% bare ground, vegetation <6” tall; and more difficult: <90% bare ground, vegetation ≥6” tall). Thirty searcher efficiency trials (*n* = 15 small birds, 10 medium birds, and 5 large birds) occurred along the fence in the only stratum present on the fence (easy visibility). Thus, in February, a total of 150 searcher efficiency trials occurred at the Project, and the same methods and number occurred during the spring season. Locations for trials were chosen by taking a randomized sample of all locations included in standardized carcass searches.

Comentado [FWS18]: Has this been evaluated as adequate to determine searcher efficiency for a single strata? Please provide justification for small sample size.

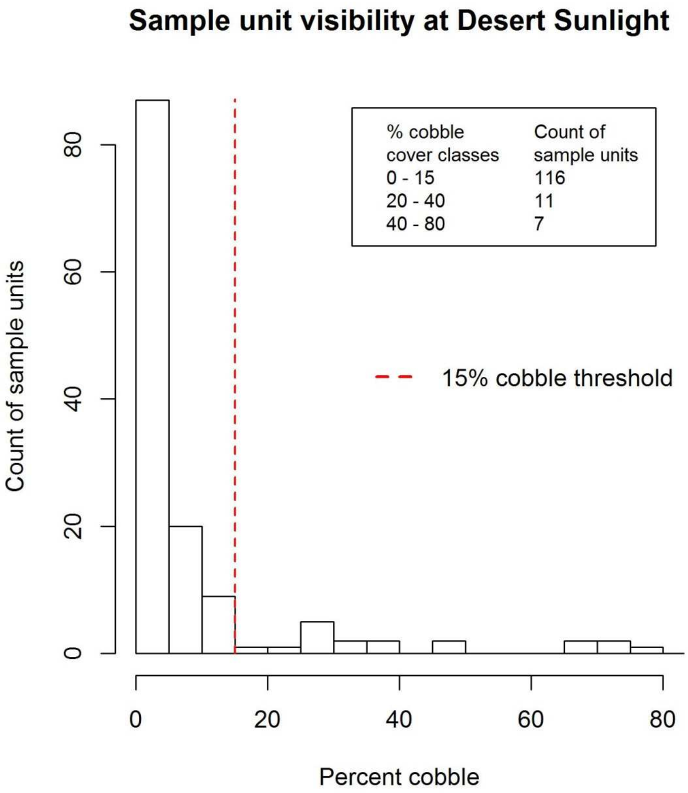

Figure 4. Frequency histogram of sample units (in the arrays only) at Desert Sunlight Solar Farm Project by estimates of cobble cover. Based on this distribution, each sample unit was assigned to one of two classes of cobble cover (<15%; >15%).

2.3.2 *Estimating Searcher Efficiency*

Comentado [FWS19]: Is searcher efficiency tested for each observer? Please provide these results along with an indication of variation in searcher efficiency across observers.

Searcher efficiency at Desert Sunlight was estimated separately for linear features (the project fence and the generation tie line), and the solar arrays, reflecting the different search methods used on arrays and linear features. For linear features, logistic regression models were fit to searcher efficiency data and AICc was used to compare models. Models including effects of carcass size (three classes) and visibility (two classes; gen-tie only), were compared to each other and the null model. Model selection indicated that best models accounted for component, carcass size, and on the gen-tie line, visibility. Once the best model was chosen and appropriate classes identified, searcher efficiency, or the proportion of carcasses detected, *p*, was calculated for each class using the following equation:

$$p = \frac{Number\ of\ Carcasses\ Observed}{Number\ of\ Carcasses\ Available}$$

The data for this analysis included all searcher efficiency trial carcasses from February and the spring 2015 season.

For the solar arrays, searcher efficiency was evaluated using a distance sampling approach (Buckland et al. 1993). Distance sampling assumes perfect detection on the transect line (at distance = 0), an assumption that is likely valid in the solar arrays given the relatively flat & vegetation-free nature of the soil surface. A curve is fitted to the observed carcass data that predicts probability of detection as a function of distance from the transect line. The mean value of this function over a specified distance, *w,* is equal to the average searcher efficiency for a transect of width *w*. One departure in the methods used here, relative to the methods presented in Buckland et al. (1993), was that for this study the detection function was estimated using trial carcasses, which meant that there were both presence (detected) and absence (not detected) data available to fit the detection function (Figure 5). The availability of both presence and absence data means that the detection function can be estimated using only trial carcasses whose distribution is known. Therefore the detection function, the average searcher efficiency among the arrays and the final fatality estimate within the arrays are all insensitive to the spatial distribution of carcasses within individual arrays, and the overall searcher efficiency estimate is valid even if the distribution of carcasses among the arrays is not uniform.

Distances of trial carcasses (trials both found and missed) from the transect line were used to fit a half-normal detection function for searches among the arrays (Figure 5). The half-normal detection function is a commonly used function for distance sampling surveys (Buckland et al. 1993). The detection function was fit with and without covariates (carcass size, visibility index, or no covariates) and AICc indicated that the best among these models included only carcass size as a covariate.

Comentado [FWS20]: Is sample size adequate to detect a difference between visibility categories?

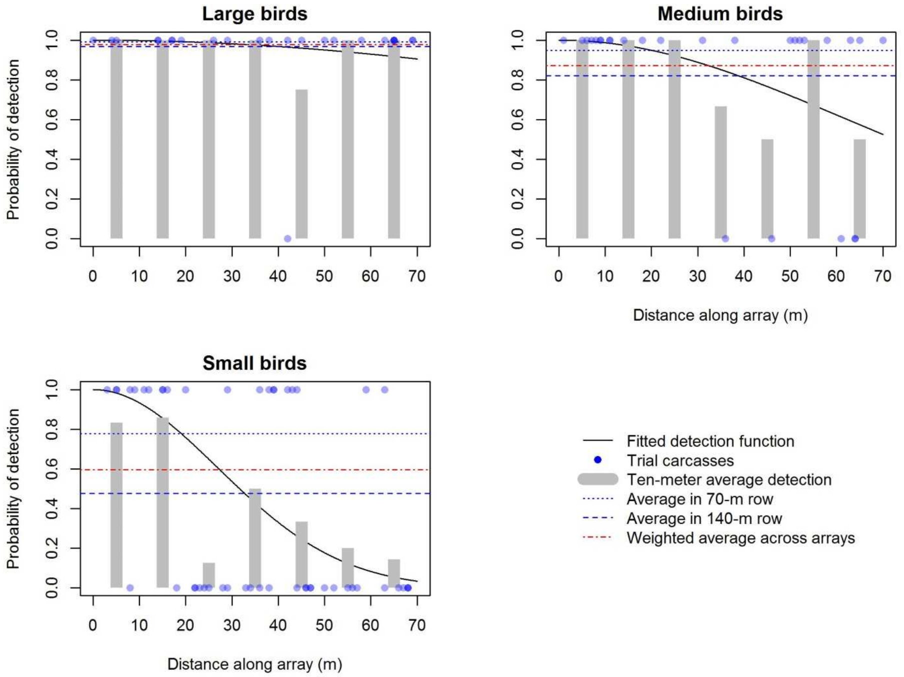

Figure 5. Estimated detection probabilities for bird carcasses by size class during spring 2015 (including February) at the Desert Sunlight Solar Farm Project, Riverside County, California. Distance sampling was used when searching solar arrays only. Average probability of detection over 70-m and 140-m panel rows in solar arrays are presented.

Because the solar arrays were surveyed by searchers who walked down both sides of the rows of panels, the width of the search transect was specified as half the width of the rows of panels. For larger birds, there is almost certainly a non-zero detection probability beyond this distance but the bias that occurs by ignoring this non-zero detection probability is conservative (i.e. the searcher efficiency is underestimated). Some solar arrays have row widths of 70 m (search transect width of 35 m) and some have row widths of 140 m (search transect width of 70 m). Searcher efficiency was higher for the arrays with a width of 70 m, and overall searcher efficiency was estimated as a weighted average based on the proportions of 70-m arrays and 140-m arrays in the sample units.

Comentado [FWS21]: Shouldn't the curves then be for 35m and 70m?

Comentado [FWS22]: How does this relate to the curves above. Detectability for small birds drops off before 70 m and presumably is near zero for greater than 70 m.

2.4 Fatality Estimator

Fatality rate estimation is a complex task due to several variables inherent to every fatality monitoring study. Carcasses may persist for variable amounts of time due to local scavenger activity or environmental conditions leading to carcass degradation over time. Carcasses and feather spots are also detected with varying levels of success based on carcass characteristics and ground cover (e.g., vegetated areas underneath the gen-tie line versus cleared areas beneath solar panels). For these reasons, it is generally inappropriate to draw conclusions based on the raw number of fatalities alone. The desire to estimate fatalities given these variables has driven the development of several statistical methods for estimating fatalities (e.g., Smallwood 2007, Huso 2010, Korner-Nievergelt 2011). All of these fatality estimation methods share a similar underlying model. Generally, the fatality estimation for a given site may be written as:

$$F=C/rp,$$

where F is the total number of fatalities, C is the number fatalities detected and included in fatality estimation, r is the probability a carcass is unscavenged and available to be found at the end of the search interval, and p is the probability of detecting a carcass (Huso 2010).

All fatality estimates were calculated using the Huso estimator, as well as 90% confidence using bootstrapping (Manly 1997). Bootstrapping is a computer simulation technique that is useful for calculating point estimates, variances, and confidence intervals for complicated test statistics. A total of 1,000 bootstrap replicates were used. The lower 5th and upper 95th percentiles of the 1,000 bootstrap estimates provide estimates of the lower limit and upper limit of an approximate 90% confidence interval on all estimates.

2.5 Incidental Reporting

Some detections were outside standardized search areas, or were within search areas but not observed during standardized searches. Such detections were found by WEST avian biologists and operational personnel and were considered “incidental” detections. When found by operational personnel, these detections were reported to WEST avian biologists for documentation. Data on incidental detections are reported here, as well as in the Desert Sunlight SPUT Avian Injury and Mortality Report Forms February – May 2015. All detections made in search areas were included in fatality estimates, regardless of whether they were detected incidentally or during searches.

3.0 MONITORING RESULTS

3.1 Summary of Avian Detections

During spring 2015 (including February), a total of 25 avian detections (including one injured bird and incidentals) of 13 identified species were recorded (Table 2). The most numerous detection of an identified species was common loon (*Gavia immer*)~~,~~ ~~but~~ with ~~only~~ four detections. Most detections (n = 12, or 48.0% of total detections) occurred in the solar arrays (Figures 2 and 3; Tables 2, 3, and 4). Eighteen (72%) detections were made during standardized carcass searches and seven (28.0%) were documented as incidentals. For fresh carcasses, body weights and weather conditions the preceding nights are described in Appendix B.

Table 2. Number of individual bird detections, by species, during spring 2015 (including February) at the Desert Sunlight Solar Farm Project, Riverside County, California. Overhead lines include the gen-tie line and medium voltage overhead lines that co-occur with the solar arrays.

Common Name	Scientific Name	Migration Behavior*	Guild	Count	Project Component
common loon	*Gavia immer*	diurnal	waterbirds/waterfowl	4	solar arrays
common raven	*Corvus corax*	resident	corvids	1	solar arrays
greater roadrunner	*Geococcyx californianus*	resident	cuckoos	1	overhead lines
mallard	*Anas platyrhynchos*	variable	waterbirds/waterfowl	1 1	fence overhead lines
Nashville warbler	*Oreothlypis ruficapilla*	nocturnal	warblers	1	overhead lines
pied-billed grebe	*Podilymbus podiceps*	nocturnal	waterbirds/waterfowl	1	solar arrays
Savannah sparrow	*Passerculus sandwichensis*	nocturnal	grassland/sparrows	1	solar arrays
sora	*Porzana carolina*	nocturnal	rails/coots	1	solar arrays
Townsend's warbler	*Setophaga townsendi*	unresolved	warblers	1	overhead lines
unidentified bird (small)	–	–	unidentified birds	1	solar arrays
unidentified bird (unknown size)	–	–	unidentified birds	1 2	solar arrays overhead lines
unidentified grebe	–	nocturnal	waterbirds/waterfowl	1	solar arrays
unidentified hummingbird	–	–	swifts/hummingbirds	1	solar arrays
western tanager	*Piranga ludoviciana*	nocturnal	tanagers	1	overhead lines
western wood-pewee	*Contopus sordidulus*	nocturnal	flycatchers	1	O&M building

Table 2. Number of individual bird detections, by species, during spring 2015 (including February) at the Desert Sunlight Solar Farm Project, Riverside County, California. Overhead lines include the gen-tie line and medium voltage overhead lines that co-occur with the solar arrays.

Common Name	Scientific Name	Migration Behavior*	Guild	Count	Project Component
white-winged dove	*Zenaida asiatica*	variable	doves/pigeons	1	fence
				2	overhead lines
Wilson's warbler	*Cardellina pusilla*	nocturnal	warblers	1	overhead lines
Total				**25**	

* See literature cited for migration behavior references; information for most species was taken from the respective species accounts found in Birds of North America (BNA) Online (http://bna.birds.cornell.edu/bna/); where information on migration behavior was lacking in BNA accounts, Newton (2008) or Murray (2004) were used.

Table 3. Total avian detections by Project component and detection category during spring 2015 (including February) at the Desert Sunlight Solar Farm Project, Riverside County, California. Overhead lines includes the gen-tie and medium voltage overhead lines that co-occur with the solar arrays. Only carcasses found within search areas were included in fatality estimates.

	Inside carcass search area		Outside carcass search area	
Project Component	**Carcass search**	**Incidental**	**Carcass search**	**Incidental**
Fence	1	0	0	1
O&M Building	0	0	0	1
Overhead lines	7	1	0	1
Solar arrays	6	1	3	2

Table 4. Total avian detections (including incidentals) by Project component and suspected cause of death during spring 2015 (including February) at the Desert Sunlight Solar Farm Project, Riverside County, California. Overhead lines includes the gen-tie and medium voltage overhead lines that co-occur with the solar arrays.

	Suspected Cause of Death*				
Project Component	**Collision**	**Predation**	**Other**	**Unknown**	**Percent of Total**
Fence	1	0	0	1	8.0
O&M building	0	0	1	0	4.0
Overhead lines	7	1	1	1	40.0
Solar arrays	1	0	4	7	48.0
Percent of Total	**36.0**	**4.0**	**24.0**	**36.0**	**100.0**

* Suspected cause of death was assigned based on available evidence and proximity of detection to Project infrastructure. Detections that had evidence of scavenging were assigned as "unknown" because it can't be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) had a suspected cause of death attributed to the respective Project component. However, in the absence of a completed necropsy, ~~it should be noted that~~ there is ~~substantial~~ some uncertainy associated with cause of death assignments because no events were directly observed.

Comentado [FWS23]: Was proximity to project features evaluated? Please describe how this information was utilized. Proximity distances may provide insights into which features may pose the greatest risks.

Comentado [FWS24]: Since scavenger rates are so high, this definition too easily categorizes carcasses as unknown. Low levels of scavenging should not exclude birds from a more thoughtful evaluation of the cause of the mortality. Other criteria should be considered, including patterns of disturbed dust on solar panels, proximity to a feature with collision risk. Such a blanket categorization, probably masks useful information.

3.2 Temporal Patterns of Avian Detections

The number of detections recorded daily during the reporting period ranged from zero to two (Figure 6). The period from March 30 to May 27 was characterized by slightly higher numbers of detections with more days with two detections than the previous period. The number of detections per day represents those discovered during standardized carcass searches and incidentally.

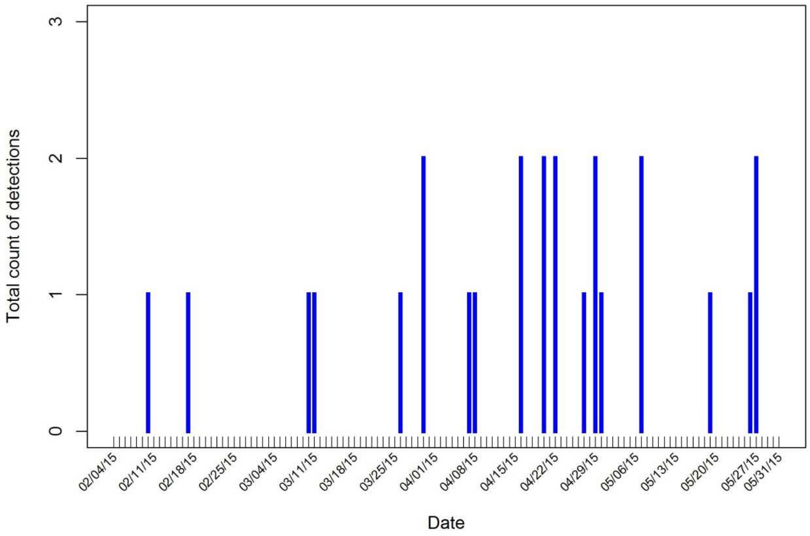

Figure 6. Total number of detections by date during spring 2015 (including February) at the Desert Sunlight Solar Farm Project, Riverside County, California.

3.3 Spatial Distribution of Avian Detections

Comentado [FWS25]: Spatial distribution of different taxonomic groups should be discussed, particularly as more data come in.

3.3.1 *Detections by Project Component*

During the reporting period, detections were documented from the solar arrays, perimeter fence, gen-tie line, MVOH lines within the solar field, and the O&M building (Tables 2, 3, and 4). Of the 12 detections within the solar arrays, most (7, or 58.3%) were assigned to the "unknown" category for suspected cause of death.

3.3.2 *Feather Spot Detections*

Eight (32.0%) of the 25 detections consisted only of feather spots. Along the fence, one detection (4.0%) was a feather spot. Three detections (12.0%) along the overhead lines were feather spots. Four detections (16.0%) in the solar arrays were feather spots.

3.4 Detections of Injured Birds

One bird was located during the reporting period that was injured. A mourning dove (*Zenaida macroura*) was discovered on April 22 along the northern section of the perimeter fence. The bird had an obvious injury to its breast. Because the bird was found the day after the tornado struck the Project, the injury may have been a result of the storm. The bird was taken to Coachella Valley Wild Bird Center and left with Linda York for rehabilitation. Numerous attempts to determine the final outcome for the dove were unsuccessful. The single injured bird detection was included in the fatality estimates.

Comentado [FWS26]: This is a good (and more conservative) practice, even if the dove were successfully released, because the viability of the released bird is unknown..

3.5 Summary of Bat Detections

No bats were located during the spring 2015 season (including February).

3.6 Carcass Persistence Trials

Based on carcass persistence data from the spring 2015 season, 20 survival models were compared for relative quality using the corrected AICc score, as suggested in Huso (2010). The AICc score provides a relative measure of model fit and parsimony among a selection of candidate models. Carcass size is a potentially important variable, as larger carcasses tend to persist longer and may be more likely to leave feather spots which persist for long durations, whereas smaller carcasses may be more likely to be completely removed.

The model with lowest AICc score is typically chosen as the "best" model relative to other models tested; however, any model within two AICc points of the best model is considered competitive with the best model (Burnham and Anderson 2004). The top model had a ∆AICc value of 2.84 and included carcass size (small, medium or large), and location (solar arrays/fence or generation-tie line) with a Weibull-distributed removal time. Estimates of carcass removal time and persistence probabilities are provided in Table 5.

Table 5. Mean carcass removal time and probability of a carcass persisting through the 7-day search interval during the reporting period at the Desert Sunlight Solar Farm Project, Riverside County, California.

Carcass size	Project component	Mean removal time (days)	Probability of persistence
Small	Arrays/fence	5.7	0.54
Small	Overhead lines	2.0	0.29
Medium	Arrays/fence	29.8	0.82
Medium	Overhead lines	13.7	0.71
Large	Arrays/fence	126.8	0.94
Large	Overhead lines	14.6	0.72

Comentado [FWS27]: This looks like there may be an effect on persistence time from being outside the fence. This may be due to differences in the scavenger community. Was this tested?

3.7 Searcher Efficiency Trials

During the reporting period, a total of 300 searcher efficiency trials were placed at the Project. Most trials were available to be found, but some disappeared before or during the trial. Overall, 120 trials were placed in the solar arrays and 102 were available to be found; 60 trials were placed along the perimeter fence (inner perimeter only) and 59 were available to be found; and 120 trials were placed along the gen-tie line and 105 were available to be found.

Comentado [FWS28]: How was this broken down by visibility categories and size classes? See Appendix C?

In the solar arrays, the model that included an effect of carcass size was chosen as the best model to estimate searcher efficiency. Within the solar arrays, searcher efficiency was influenced by carcass size: 60.0% for small birds, 87.2% for medium birds, and 97.3% for large birds. Along the fence, searcher efficiency ranged from 79.3% to 100% depending on carcass size class. Along overhead lines, searcher efficiency ranged from 53.9% to 87.8%. Detailed estimates of searcher efficiency estimates specific to each component and carcass size are reported in Appendix C.

3.8 Fatality Estimates

Fatality estimates were calculated separately for each component (solar arrays, fence, and overhead lines). Ultimately, nine detections were excluded from the fatality analysis: five were found outside standardized search areas; one was estimated to be older than the 7-day search interval (Huso 2010); and three were both outside standard search areas and estimated to be older than the 7-day search interval.

During spring 2015, there were an estimated total 111 fatalities (90% CI: 58 - 193) at the Project. Of these, 49 fatalities (44.1%; 90% CI: 19 – 86) were estimated for the solar arrays, 2 fatalities (1.8%; 90% CI: 2 – 4) were estimated for the fence, and 60 fatalities (54.1%; 90% CI: 16 – 132) were estimated for the overhead lines (gen-tie and medium voltage overhead lines combined). There were an estimated 0.02 fatalities per acre (within the solar field only) and an estimated 0.20 fatalities per nameplate MW at the Project. A complete list of estimates for each Project component and carcass size class with confidence intervals is presented in Appendix C.

4.0 DISCUSSION

The 2015 spring season represented the first full season of standardized monitoring at Desert Sunlight per the BBCS. Searcher efficiency trials and carcass removal trials were conducted concurrently at the solar arrays, fencelines, and along the gen-tie line. Data from these trials were used to produce fatality estimates adjusted for searcher efficiency and carcass persistence bias. Although these estimates were produced from a statistically robust sample, only limited inference may be drawn from a single season of data. These results should be considered preliminary because estimating carcass persistence, searcher efficiency, and adjusted numbers of fatalities within each season represents information based on a limited sample size. As more data are collected throughout the monitoring year (and additional quality assurance/quality control measures occur, for example characterizing feather spots to species or size class), data from all seasons may be pooled. At that time, data will be tested for seasonal differences retrospectively, but because seasonal estimates will be produced from the much larger annual data set, they may differ from what is reported here because they are based on a larger, more informative sample.

4.1 Carcass Persistence and Searcher Efficiency Trials

The degree to which carcasses persist on the landscape depends on a variety of factors reflecting seasonal and inter-annual variation in habitat, climate, and the scavenger community. The composition and activity patterns of the scavenger community often vary seasonally as birds migrate, new juvenile birds and mammals join the local population, and mammalian scavengers variably hibernate or estivate. The scavenger community may also vary substantially from year to year because of variation in annual reproduction and survival related to changes in landscape condition. Climatic conditions that vary seasonally and annually also may contribute to variation in carcass decay and removal rates due to variation in temperatures, solar insolation, wind patterns, and the frequency of flooding events. Thus, rates of carcass persistence reported here should be interpreted cautiously as they may change over the coming months.

Searcher efficiency was influenced by Project component, carcass size, and visibility class (along the gen-tie only). In the solar arrays, searcher efficiency was high (> 0.5) for all carcass size classes and this is likely influenced by the limited vegetation cover beneath solar panels. Beneath the gen-tie line vegetation cover is higher in some portions of the strip transects, and results reported here support the hypothesis that visibility class is a factor in searcher efficiency along the lines.

For the current analysis, searcher efficiency in the solar arrays was assumed to be best predicted by a half-normal distribution. For future analyses, AICc will be used to compare and choose the best among multiple detection functions.

Searcher efficiency trials for this Project will be repeated seasonally. The desert landscape in which this Project is located generally changes little with the seasons, save for brief periods following winter and spring rains when floods may occur and blooming plants may flourish. A recent meta-analysis involving data from more than 70 wind-energy projects suggested that including habitat visibility class as a predictive variable generally eliminated any otherwise apparent seasonal effects on searcher efficiency (Smallwood 2013). Further, the possibility exists that searcher efficiency varies seasonally in some cover types but not others. Data from searcher efficiency trials conducted over the coming seasons will therefore continue to be tested for effects of habitat visibility class rather than effects of season.

Comentado [FWS29]: Shouldn't both season and habitat visibility class be evaluated?

4.2 Distribution of Fatalities and Fatality Estimates

The number of detections was more or less evenly distributed across the spring season, and there were no clear associations between number of detections and date. Given the small number of detections overall, it is premature to draw any conclusions about the spatial distribution of carcasses.

Detections attributed to an unknown cause accounted for 36.0% of all detections during the reporting period, and the distribution of the unknown cause detections varied by project component with 48.0% occurring in association with the solar arrays. Of the 12 detections made in the solar arrays, 16.0% were feather spots. Determining a cause of mortality from a feather spot is challenging because there is rarely visible evidence available on which to determine a cause of death. Thus, feather spots with an unknown cause of mortality could be encountered anywhere birds occur, and an unknown cause of a sizeable proportion of the carcasses is not unique to the Project. Further, the relatively large proportion of feather spots (32%) among the detections for the Project as a whole may inflate the fatality estimate when unknown cause detections are included based on the potential for multiple feather spots resulting from one fatality, feather spots resulting from predation not associated with the facility, or other causes.

Comentado [FWS30]: Again, a more thoughtful evaluation of cause of mortality should be done to reduce the number of unknowns. In particular, mortalities associated with project features that may present a collision risk are probably better categorized as collisions (i.e., solar panels and overhead electrical lines).

Comentado [FWS31]: This is the same as for Genesis.

1.0 Introduction

This Year 4 First Quarter Report for January 1 through March 31, 2015 provides bird and bat information as specified in the Topaz Solar Farms Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP and BMAP; Althouse and Meade, Inc. June 2011). Section 5.5 of the ABPP and BMAP describes information to be included in reports and requires quarterly reports to be submitted to the County of San Luis Obispo (County), U.S. Fish and Wildlife Service (USFW) and the California Department of Fish and Wildlife (CDFW). The Avian and Bat Protection Plan (ABPP; Section 2.0 of this report) and Bird Monitoring and Avoidance Plan (BMAP; Section 3.0 of this report) are requirements of County of San Luis Obispo Conditions of Approval (COA) 61 and 62, and were prepared in consultation with USFWS and CDFW.

1.1 Construction Status

Construction of the Topaz Solar Farms project was completed in December 2014. All 22 solar array blocks were transferred to Operations & Maintenance (O&M) by October 2014 (Table 1). Exhibit 1 in Section 5.0 illustrates construction status through December 2014.

TABLE 1. CONSTRUCTION STATUS BY BLOCK. Date of transfer to O&M is provided for Blocks 1-22.

Block(s)	Month and Year Transferred to O&M	Block(s)	Month and Year Transferred to O&M
1	March 2013	12	March 2014
2	March 2013	13	April 2014
3	March 2013	14	January 2014
4	April 2013	15	February 2014
5	April 2013	16	May 2014
6	March 2013	17	June 2014
7	May 2013	18	July 2014
8	June 2013	19	August 2014
9	July 2013	20	September 2014
10	December 2013	21	September 2014
11	March 2014	22	October 2014

2.0 Avian and Bat Protection Plan

The ABPP monitoring program compiles general information on bird and bat presence, interactions with facility components, injuries, and mortality at the Topaz Solar Farms (TSF) project. This task is completed by the project biologists as part of routine daily biological monitoring. In blocks under Operations and Maintenance (O&M) control, data is collected from a variety of sources, including pre-activity surveys, O&M technician reports, and during field work conducted for BMAP studies. Information regarding the detailed bird use and mortality risk assessment study is reported in Section 3.0.

For the ABPP, this quarterly report provides information collected during the period from January 1 through March 31, 2015.

2.1 General Bird Surveys

2.1.1 Methods

General bird surveys are conducted on and around the TSF project site on a daily basis five days a week throughout the year by project biologists. Lists of bird species observed by each biological monitor are recorded daily.

2.1.2 Results

Monitors recorded a total of 61 species of birds in January, February, and March 2015. Of the 61 species, 8 were waterbirds and 11 were raptors. Some of the 8 waterbird species were observed in lands surrounding Topaz including a private pond less than a thousand feet from TSF, and others were observed flying over TSF without using project features as habitat. Table 1 lists all bird species observed in this quarter with information on observation frequency.

Table 2. January – March 2015 General Bird Survey Results. All bird species recorded this quarter are listed. Top twenty species most frequently observed, waterbirds, and raptors are indicated.

Western Kingbird			
Western Meadowlark	✓		
White-crowned Sparrow	✓		
White-tailed Kite			✓
Yellow-rumped Warbler			

2.2 Nesting Activity

Nest searches were not conducted during this reporting period. No nests were incidentally observed or reported by O&M technicians.

2.3 Avian and Other Wildlife Mortality

General biological monitoring of the Topaz work area documented bird, bat, and other wildlife mortality, as required by COA 62. All mortality identified on site during this reporting period is provided in Table 3. Cause of death is reported when known. Several of the avian fatalities identified were feather spots, so cause of death could not be confirmed. "Probable" is used for a confidence of >50 percent in the cause of death determination, while "Possible" indicates 1-50 percent confidence. "Valid" indicates 100 percent confidence in the cause of death determination. This table includes all fatalities found in areas managed by Operations and Maintenance.

TABLE 3. JANUARY – MARCH 2015 AVIAN AND OTHER WILDLIFE MORTALITY. Bird and other wildlife mortality detected at the Topaz Solar Farms from January 1 to March 31, 2015. Asterisk indicates it was found during formal fatality surveys.

Month	Species	Location	Cause of Death
Jan.	Mourning Dove	Block 13	Possible Predation
	Mourning Dove	Block 13	Possible Predation
	Western Meadowlark*	Block 9 Array 14	Unknown
	Mourning Dove	Block 13 Array 8	Possible Predation
	Mourning Dove	Block 14 Array 1	Probable Predation
	Unknown Blackbird	Block 15 Array 16	Unknown
	Red-Tailed Hawk	Fence in Block 1 Array 19	Probable Collision
	Domestic Chicken	Block 17 Array 1	Possible Predation
Feb.	Domestic Chicken*	Block 20 Array 1	Possible Predation
Mar.	Domestic House Cat	Block 6	Unknown
	Western Meadowlark*	Block 7 Array 4	Unknown
	Common Raven	Block 11 Medium Voltage Collector Lines	Collision
	Common Raven (2)	Block 13 Photovoltaic Combining Switchgear	Electrocution
	Common Raven	Block 12 Photovoltaic Combining Switchgear	Electrocution

2.4 Adaptive Management

No adaptive management practices were implemented during the period from January through March 2015.

2.5 Bat Surveys

2.5.1 Methods

Acoustic monitoring surveys for bats on the project site were conducted one night per month using a Pettersson D240x (Pettersson Elektronik, Sweden) bat detector and Sonobat® (v.3.1 US west; DNDesign, Arcata, CA) acoustic analysis software. Sound frequencies in the range utilized by bats (10 to 120 kHz) were detected and synthesized into time-expanded sound files and analyzed by Sonobat® software. Surveys were initiated near dusk, when bats commonly begin foraging. Monitoring periods for each survey were limited to the battery life of the Pettersson detector and typically ranged from three to six hours depending on the number of sound files detected. On January 28, the detector was deployed on the perimeter fence at the northeastern corner of Block 7. On February 10 and March 30, the bat detector was placed on a T-post near the parking lot west of the Operations and Maintenance building. All sound files recorded were analyzed for bat calls. Any identification to species was determined with a discrimination probability of 0.95 or higher using Sonobat® software.

2.5.2 Results

From January through March 2015, bats were not detected at Topaz Solar Farms. The decrease in bat activity observed during the 2015 winter months was expected. Seasonal fluctuations in distribution and activity has been documented in many species of bats throughout North America (e.g. O’Shea and Vaughan 1977, Cryan 2003), including changes in wintering range and activity. Similar decreases in bat abundance and species richness were also observed at Topaz Solar Farms during winter 2013-2014 and are likely to occur each winter.

3.0 Bird Monitoring and Avoidance Plan

The BMAP study analyzes avian use surveys and avian fatality surveys to produce a risk index for various project components deemed to be potentially dangerous to birds, including array areas, overhead power lines and the substation. Off-site grassland reference sites are used to gauge background mortality levels. Results are reported in this first quarter report for Avian Use Surveys (Section 3.1), Avian Fatality Surveys (Section 3.2), and for bias trials (Section 3.3). Risk index calculations will be provided in the annual report.

3.1 Avian Use Surveys

3.1.1 Methods

Avian Use Surveys have been conducted monthly from November 2011 through March 2015, and will continue through 2017 to satisfy the three-year post construction monitoring requirement. Each month, 63 randomly selected survey points are completed, including 31 inside existing array areas, 18 along existing overhead power lines, 10 in grassland reference sites and 4 at energized equipment (substation). At each point, a 10 minute bird use count is conducted within a 50 meter radius of the surveyor. Avian Use Survey points are randomly selected each month across all six phases of the project and in off-site grassland reference areas (Exhibit 3).

3.1.2 Results

The four Survey Area Categories used as treatment types in this study comprise different habitat elements that influence species composition, abundance and richness.

The Array Area category includes surveys conducted within solar array areas during active construction and in completed form. The habitat consists of rows of passive (non-moving) photovoltaic solar panels mounted to steel racking ranging from approximately 2 to 5 feet off the ground. The ground is seeded with a native seed mix to revegetate array areas to naturalized grassland habitat; vegetation density varied from 0 to 60 percent cover. Array Area survey point areas may also include perimeter fences, photovoltaic combining switchgear houses, as well as array roads.

The Energized Equipment category includes point counts conducted around the perimeter of the substation. The survey area includes the substation perimeter fence, transformers, power lines, and other electrical components. Within the substation fence the ground is gravel with no vegetation. Outside the perimeter fence, the ground is bare dirt with some patches of grass and forbs.

Overhead Powerline surveys represent areas underneath medium-voltage collector lines within the project. Vegetation varies depending on location. Most powerlines are along array or perimeter access roads, however some locations are outside the fenced project areas in annual grassland habitat.

Reference Sites are composed of annual grassland habitat. They included point counts conducted on annual grassland in mitigation lands owned and managed by California Department of Fish and Wildlife or Stewardship Land not developed by TSF.

In January, February, and March 2015, 189 avian point counts were conducted in the 4 Survey Area Categories totaling 366.8 acres of survey area. During these surveys, species composition consisted of 27 different bird species. Bird abundance is examined as total number of detections per species as well as average number of detections per Observation Point (Table 4). The most abundantly detected species, listed in decreasing order of total detections, were: horned lark (1,275 detections), Brewer’s blackbird (370), house finch (263), savannah sparrow (108), common raven (79), western meadowlark (70), mourning dove (32), American pipit (30), European starling (24), and Eurasian collared-dove (18).

The most frequently encountered species, the horned lark, was detected more than three times as often as that of that of the second most frequently encountered species, Brewer’s blackbird. It was detected three times more frequently in Grassland/Reference than in Overhead Powerline areas. The Array Area category had the lowest average detections per Observation Point.

TABLE 4. SPECIES COMPOSITION AND ABUNDANCE. All bird species detected during Avian Use Surveys in January, February, and March 2015 are listed, with the average number of bird use detections per observation point calculated for each of the four survey area categories. Total detections for each species and each survey area type are provided in far right column and bottom row. Species are listed in decreasing order of abundance according to the total detections column.

Species	**Array Area** Ave. Detections per Obs. Pt.	**Energized Equipment** Ave. Detections per Obs. Pt.	**Overhead Powerline** Ave. Detections per Obs. Pt.	**Grassland/ Reference** Ave. Detections per Obs. Pt.	**Total Detections**
Horned Lark	1.39	3.92	5.67	17.20	6.75

Golden Eagle	0.00	0.00	0.00	0.02	0.01

Species	**Array Area** Ave. Detections per Obs. Pt.	**Energized Equipment** Ave. Detections per Obs. Pt.	**Overhead Powerline** Ave. Detections per Obs. Pt.	**Grassland/ Reference** Ave. Detections per Obs. Pt.	**Total Detections**
Northern Harrier	0.00	0.00	0.00	0.02	0.01
Prairie Falcon	0.00	0.00	0.00	0.02	0.01
White-crowned Sparrow	0.00	0.08	0.00	0.00	0.01
Killdeer	0.00	0.08	0.00	0.00	0.01
Total Avian Detections	**562**	**152**	**412**	**1,193**	**2,319**

Species Richness was calculated as the average number of species detected at each Observation Point. Among the treatment types, Energized Equipment had the highest species richness with an overall average of 3.58 species detected per Observation Point. Reference Site had the next highest with an average of 1.98 species. Array Area and Overhead Powerline had the next lowest with 1.23 and 1.35 species per observation point, respectively (Table 5 and Figure 1).

Bird Utilization Rate (BUR) is calculated as the average number of birds observed per Observation Point. Bird Utilization Rate is calculated for the four Survey Area Categories for January through March 2015 (Table 5 and Figure 1). Reference Site had the highest BUR at 39.77 birds per Observation Point. Energized Equipment had the second highest BUR at 12.67 birds per observation point and Overhead Powerline and Array Area had the lowest with 7.63 and 6.04, respectively.

TABLE 5. AVIAN USE SURVEY POINT COUNTS AND DETECTIONS. Avian use survey point count data is provided for number of observation point counts, total area surveyed, total number of species detected, species richness and bird utilization rate. All results are from data collected in January, February, and March 2015.

Type	**Number of Obs. Pt. Counts**	**Total Area Surveyed (Acres)**	**Total No. Species**	**Ave. No. Species per Obs. Pt (Species Richness)**	**Ave. No. Birds per Obs. Pt (BUR)**
Array Area	93	180.49	9	1.35	6.04
Energized Equipment	12	23.29	7	3.58	12.67
Overhead Powerline	30	104.80	7	1.23	7.63
Reference Site	54	366.81	8	1.98	39.77
Total Combined	**189**	**366.81**	**11**	**1.66**	**12.27**

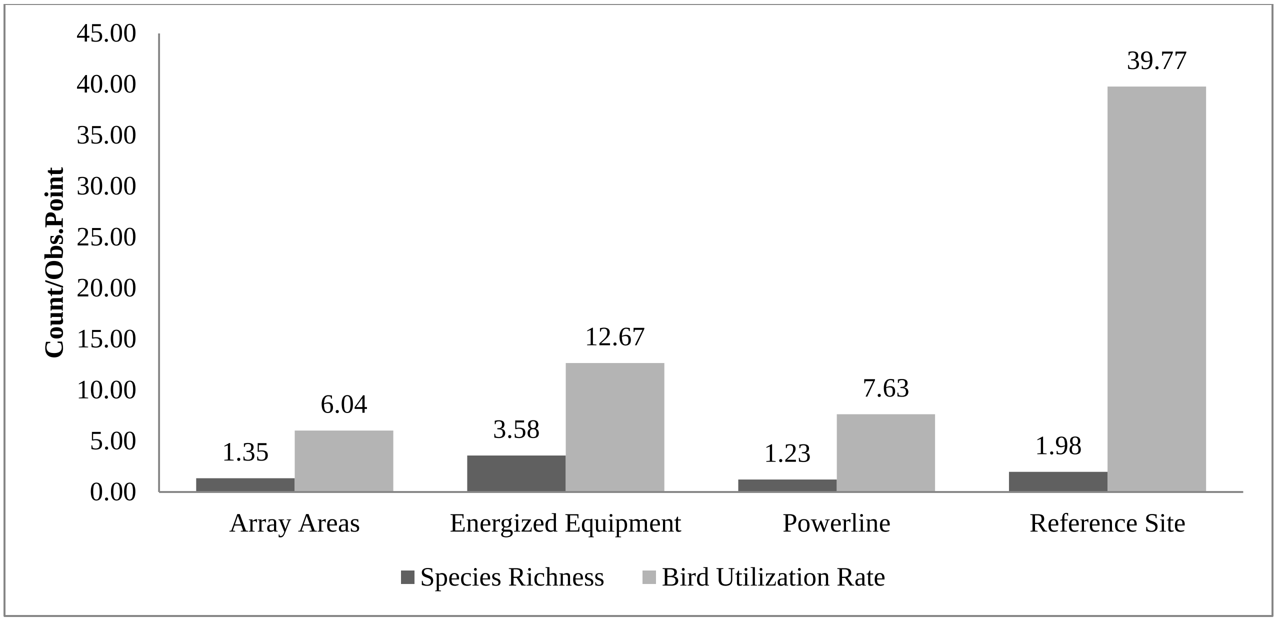

FIGURE 1. SPECIES RICHNESS AND BIRD UTILIZATION RATE. Species richness and bird utilization rate are provided for each of the 4 survey area categories for the first quarter of 2015.

3.2 Avian Fatality Surveys

3.2.1 Methods

Avian Fatality Surveys commenced upon completion of the first project components. Avian Fatality Surveys are conducted at randomly selected locations within four different survey area categories: Array Area, Overhead Powerline, Energized Equipment (Substation) and Reference Site. Search plots for Array Area, Reference Site and Overhead Powerline were defined as a transect 14 feet wide and 480 feet long, which equals the area of a typical aisle in a PV array. The area searched in the Array Area and Reference Site each month is equivalent to approximately three PV arrays. The search plot for Energized Equipment is the entire area of the substation, which is 4.48 acres. All survey areas except Energized Equipment are randomly selected using an ArcGIS random point generator having defined areas as the constraining polygon. Avian Fatality Surveys are conducted within the same search plots each day for seven consecutive days every month. Repetitive surveys increase the chance of finding fatalities in a given area before predators remove the carcass, and also facilitate per day calculations.

3.2.2 Results

Each month, January through March 2015, we completed walking Avian Fatality Surveys for all transects within each of the Survey Area Categories for seven consecutive days each. Reference Site search plots were completed for seven consecutive days each, totaling 10.4 linear miles (17.6 acres) each day of surveys. Array Area search plots were completed for seven consecutive days each, totaling 10.4 linear miles (17.6 acres) each day. Overhead Powerline search plots were completed for seven consecutive days each, totaling 4.4 linear miles (7.4 acres) each day. On days with low visibility due to poor weather, surveys were completed when conditions improved with an additional day of surveys. Energized Equipment was also surveyed for seven consecutive days, totaling 4.5 acres each day.

Three months of surveys yielded a total distance of 552 linear miles and coverage of 1,035.29 acres. These surveys resulted in discovery of five fatalities, two each in Reference Site and Array Area, and one in Overhead Powerline. Fatality rates were calculated per search plot and miles walked (Table 6). Overhead Powerline had the highest fatality rate of 0.00094 fatalities/search plot and Reference Site and Array Area each had the same fatality rate, at 0.00080 fatalities/search plot. No fatalities were found in Energized Equipment plots.

TABLE 6. BIRD FATALITY RATE. The survey results and efforts are indicated for each of the four survey area categories for the first quarter of 2015.

Survey Area Category	**Linear Miles**	**Acres**	**Search Plots**	**Total Fatalities**	**Fatality/ Search Plot**	**Fatality/ Mile**
Array Area	228	386.91	2508	2	0.00080	0.00877
Overhead Powerline	96	162.91	1056	1	0.00094	0.01041
Reference Site	228	386.91	2508	2	0.00080	0.00877
Energized Equipment	-	98.56	22	0	-	-
Total Combined	**552**	**1,035.29**	**-**	**5**	**-**	**-**

Cause of death was recorded for all fatalities, when known. The five fatalities documented during Avian Fatality Surveys in January, February, and March 2015 were classified as predation or unknown. Since it is difficult to determine cause of death with certainty, recent guidance from the U.S. Fish and Wildlife Service suggests attributing cause of death to a specific factor and including a confidence percent to indicate how confident the determination was (Table 7; Beck and Dietsch 2013). Predation as a cause of death may be higher than reported, as feather piles often could not be confidently linked to a predation event as opposed to a scavenging event, even though predation was likely the cause.

TABLE 7. CAUSE OF DEATH FOR AVIAN FATALITY SURVEY RESULTS. Cause of death tallied for avian fatalities detected within each of the four survey area categories, January – March 2015, during formal avian fatality surveys. Percentages indicate confidence level.

Survey Area Category	**Unknown**	**Predation Possible (1-50%)**	**Predation Probable (>50%)**	**Total**
Array Area	1	1	0	**2**
Overhead Powerline	1	0	0	**1**
Reference Site	0	1	1	**2**
Energized Equipment	0	0	0	**0**
Total Combined	**2**	**2**	**1**	**5**

3.3 Scavenger/Carcass Removal Trials and Searcher Efficiency Trials

3.3.1 Scavenger/Carcass Removal Trial

Scavenger removal trials were not conducted during this reporting period.

3.3.2 Searcher Efficiency Trial

Searcher efficiency trials were not conducted during this reporting period.

3.4 Discussion

This first quarter report for 2015 is the first reporting period to include data collected after the solar farm became completely operational. The last block was energized and fully operational in October 2014, and final construction activities and demobilization were completed by mid-December.

A variety of wildlife, including birds, are utilizing habitat within the completed project site. This 1st quarter winter reporting period saw the same number of fatalities in Array Areas and Reference Sites (2 each), compared with a single fatality recorded in the Overhead Powerline category. The off-site grassland Reference Site category had a bird utilization rate (BUR) 6.6 times higher than that of the Array Area category, but the bird fatality rates (BFR) were equivalent.

The 2015 Annual Report will provide more discussion of the data throughout the year and will provide comparisons of 2015 results with previous years.

EXECUTIVE SUMMARY

Avian and bat monitoring surveys were conducted from June 01 to August 30, 2015 (the reporting period) at Desert Sunlight Solar Farm Project (Project) in accordance with the Project's Bird and Bat Conservation Strategy (BBCS). For logistical reasons, fall monitoring began on Monday, August 31, 2015. Specifically, standardized carcass searches, searcher efficiency trials, and carcass persistence trials were conducted. This report represents the second seasonal report for the first year of monitoring, and summarizes monitoring methods and results for those surveys based on the procedures and requirements specified in the BBCS.

Included in this report are data from standardized carcass searches conducted during the summer season at the Project, defined as June 01 to August 30, 2015. Standardized carcass searches were conducted 1) in the solar field, consisting of a random stratified 29.5% sample of solar photovoltaic (PV) panels, 2) along inner portions of the fenceline, resulting in 74.4% of the length of the perimeter fence, and 3) along 47.9% of the total length of generation-tie (gen-tie) line from the Project fence to the Red Bluff Substation located south of Interstate 10 (I-10). Searches conducted within the summer season had intervals of approximately 21 days.

All bird and bat fatalities and injuries that were discovered by observers, referred to as "detections" in this report, including those found incidentally and during standardized carcass searches, were documented. During the reporting period, 15 avian detections were made, and there were no detections of bats.

According to specifications of the BBCS, avian detections were categorized by likely diurnal or nocturnal migration behavior, ecological guild (e.g., raptors, songbirds, etc.), facility component, and suspected cause of death. These standardized carcass search results, along with searcher efficiency and carcass persistence rates from bias trials conducted on site, were applied to a fatality estimator model (Huso 2010) to provide a preliminary estimate of the number of fatalities that occurred at the Project during the reporting period adjusted for sources of bias. The estimate is considered preliminary because the annual report may pool information from bias trials and other data across seasons which could affect seasonal estimates.

During the reporting period, carcass persistence was influenced by carcass size and Project component. Small carcasses (0-100 g) in the arrays and along the fence (combined) had a 63% chance (90% confidence interval [CI]: 48 – 76%) of persisting through the effective search interval, medium carcasses (101 – 999 g) had a 73% (55 – 86%) chance, and large carcasses (1000+ g) had a 100% chance because no removal was observed. Mean removal time within the arrays for small and medium carcasses was 15.5, and 19.2 days, respectively; mean removal time was not estimated for large carcasses because no removal was observed. Along the generation tie-line, chances of persistence for small, medium, and large carcasses were 22% (14 – 26%), 60% (37 – 74%), and 22% (14 – 26%), respectively; mean removal time for small, medium, and large carcasses was, 1.4, 14.8, and 0.9 days, respectively. Within the solar arrays, searcher efficiency was influenced by carcass size: 60.0% for small birds, 86.6% for

medium birds, and 98.1% for large birds. Along the fence, searcher efficiency ranged from 87.5% to 100% depending on carcass size class. Along the generation tie-line, searcher efficiency ranged from 43.5% to 100%.

Composition of detections during summer 2015 included eight avian guilds. Corvids comprised the majority of detections (n = 3): there were two detections each within the doves/pigeons, rails/coots, and waterbirds/waterfowl guilds. No bats have been detected since monitoring began at the Project.

Using the Huso (2010) fatality estimator model, during summer 2015, there were an estimated total 148 carcasses (90% CI: 10 – 365) at the Project. Of these, 44 carcasses (27.5%; 90% CI: 8 – 64) were estimated for the solar arrays and 104 carcasses (66.9%; 90% CI: 2 – 339) were estimated for the gen-tie line. While we are required to report the gen-tie estimates per the approved BBCS, these estimates are not reliable due to the high rates of scavenging that were observed during the limited trials at the gen-tie and the low number of carcasses detected (n = 2 in the fatality analysis). No carcasses were estimated for the perimeter fenceline because there were no detections made along the fence. All of these estimates should be interpreted with caution because variance estimates are in general unreliable when carcass counts are low (< 5 per category). Other projects (e.g. Ivanpah) are not reporting estimates when carcass counts are less than or equal to five. However, the TAG has asked for both the estimates and confidence intervals for this project with the appropriate caveat added. There were an estimated 0.017 fatalities per acre (within the solar field only; 44 estimated carcasses/2,585 acres) and an estimated 0.08 fatalities per nameplate MW (44 estimated carcasses/550 MW) within the solar field.

1.0 INTRODUCTION

1.1 Project Background

Desert Sunlight 250, LLC and Desert Sunlight 300, LLC (collectively, Desert Sunlight) constructed and operates the Desert Sunlight Solar Farm Project (referred to in this report as "Project"), which consists of two main components: 1) a 550-megawatt (MW) photovoltaic (PV) generating facility; and 2) a 220-kilovolt (kV) generation interconnection (gen-tie) line. The Project comprises approximately 1,700 hectares (ha; 4,200 acres) of land administered by the Bureau of Land Management (BLM) six miles north of Desert Center in Riverside County, California (Figure 1).

1.2 Monitoring Plan Overview and Goals

A Bird and Bat Conservation Strategy (2014; “BBCS”) was prepared by the Project proponent in collaboration with the U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), and BLM to guide comprehensive monitoring of impacts to birds and bats associated with operation of the Project. Final agency approval of the BBCS occurred in December 2014. Amendments to the sampling protocol along some portions of the Project fenceline were made by Desert Sunlight and approved by the BLM on February 11, 2015.

The BBCS details post-construction monitoring to be conducted and the data analysis and reporting processes that will be implemented by Desert Sunlight in collaboration with the USFWS, CDFW, and BLM. As identified in the BBCS, they are:

1. Estimate overall annual avian fatality rate and species composition associated with the Project infrastructure. This estimate will include mortality associated with solar arrays, overhead lines including the gen-tie line, perimeter fence and other features of the Project that may result in injury and fatality.
2. Determine whether there are spatial and temporal/seasonal patterns of mortality associated with project infrastructure (e.g., different fatality rates near panels on the edge of the arrays vs. the interior area of the arrays).
3. Provide information that will assist the BLM in consultation with the USFWS in understanding which species and potentially which regional populations are at risk.
4. Collect data in such a way that the BLM in consultation with the USFWS may make comparisons with other solar sites.

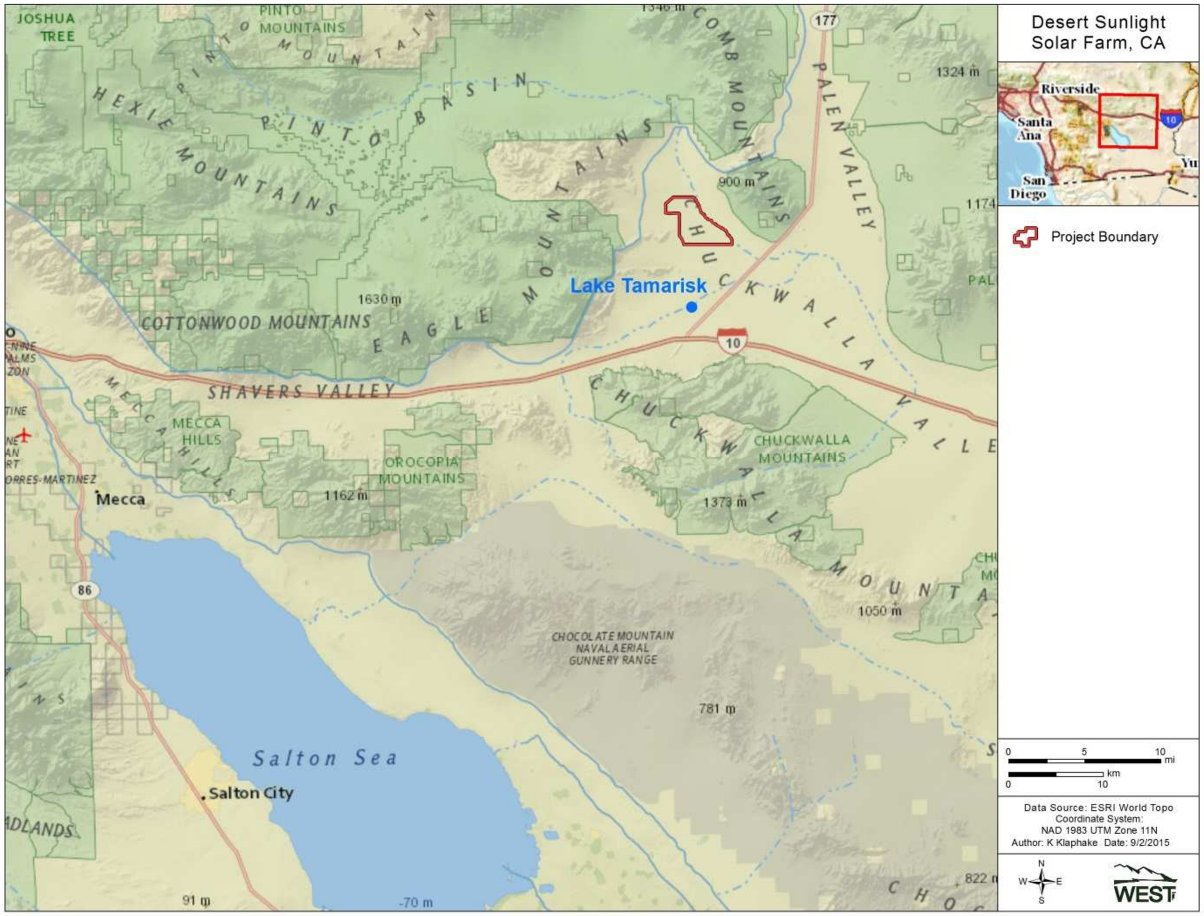

Figure 1. Desert Sunlight Solar Farm Project vicinity map, Riverside County, California.

1.3 Purpose of This Report

This report represents the second seasonal report for the first year of monitoring summarizing monitoring methods and results for avian and bat fatalities and injuries based on the procedures and requirements specified in the approved BBCS. This report covers the period June 01 to August 30, 2015, or the 2015 summer season. For logistical reasons, fall monitoring began on Monday, August 31, 2015. All carcasses and injuries that were discovered by observers are referred to as “detections” in this report. As stated in the approved BBCS, this seasonal report includes the observed detections for likely diurnal, and likely nocturnal species, and for ecological guilds of interest (e.g., raptors, water-associated birds, passerines), for each of the facility types and suspected causes of death. Species composition of detections and the results of the bias trials are also reported. This report presents information related to the spatial distribution of detections, but no formal statistical analysis of the spatial distribution of carcasses will be conducted until the end of the monitoring year, given the limited data presently available.

2.0 METHODS

The BBCS describes the methods by which monitoring and certain analyses, including compilation of the overall fatality estimate, will occur. Below is an abridged description (see BBCS for detailed methods).

2.1 Standardized Carcass Searches

This section describes areas surveyed, the timing and frequency of searches, and the methods by which standardized searches were conducted to identify dead/injured birds and bats at the Project. Dead or injured birds and bats are called detections in this report to provide consistency in naming. This section also describes the methods for conducting carcass removal and searcher efficiency trials; how data were reported and analyzed; and the methods for producing fatality estimates for the Project.

2.1.1 *Areas Surveyed*

Standardized carcass searches were conducted at sampling units, which include the solar arrays (Table 1, 2; Figure 2); the “fenceline” defined as the perimeter fence for the Project (Table 1, Figure 2); and the gen-tie line (from the Project fence to the Red Bluff Substation on the south side of I-10; Table 1, Figure 3). Some overhead lines co-occur with solar arrays (medium voltage overhead lines [MVOH]). The MVOH were part of standardized carcass searches to the extent that they co-occured with solar arrays included in the sample (Table 2; Figure 2).

Table 1. Areas included in standardized carcass searches at the Desert Sunlight Solar Farm Project during summer (June 01 – August 30) 2015.

Project Component	Total Size	Units	% of Component Searched
Solar arrays	1045.9	Hectares	29.5[1]
Fence	16.7	Kilometers	99.0[2]
Gen-tie line	19.2	Kilometers	47.9[3]

[1] Percent area that was searched in summer 2015. Slightly less than 30% total because of unequally-sized arrays.

[2] 74.4% of the fence is fully accessible and surveyed following the standard protocol, while approximately 25% of the fence is surveyed from a distance. Fatality rates estimated for sections of the fence that are sampled were extrapolated to sections of the fence where the standard monitoring protocol cannot be used, as described in section 4.2.6 of the approved Desert Sunlight BBCS. A very short segment near the gate is not sampled due to restoration activities.

[3] 52.1% of the gen-tie will be sampled in 2016.

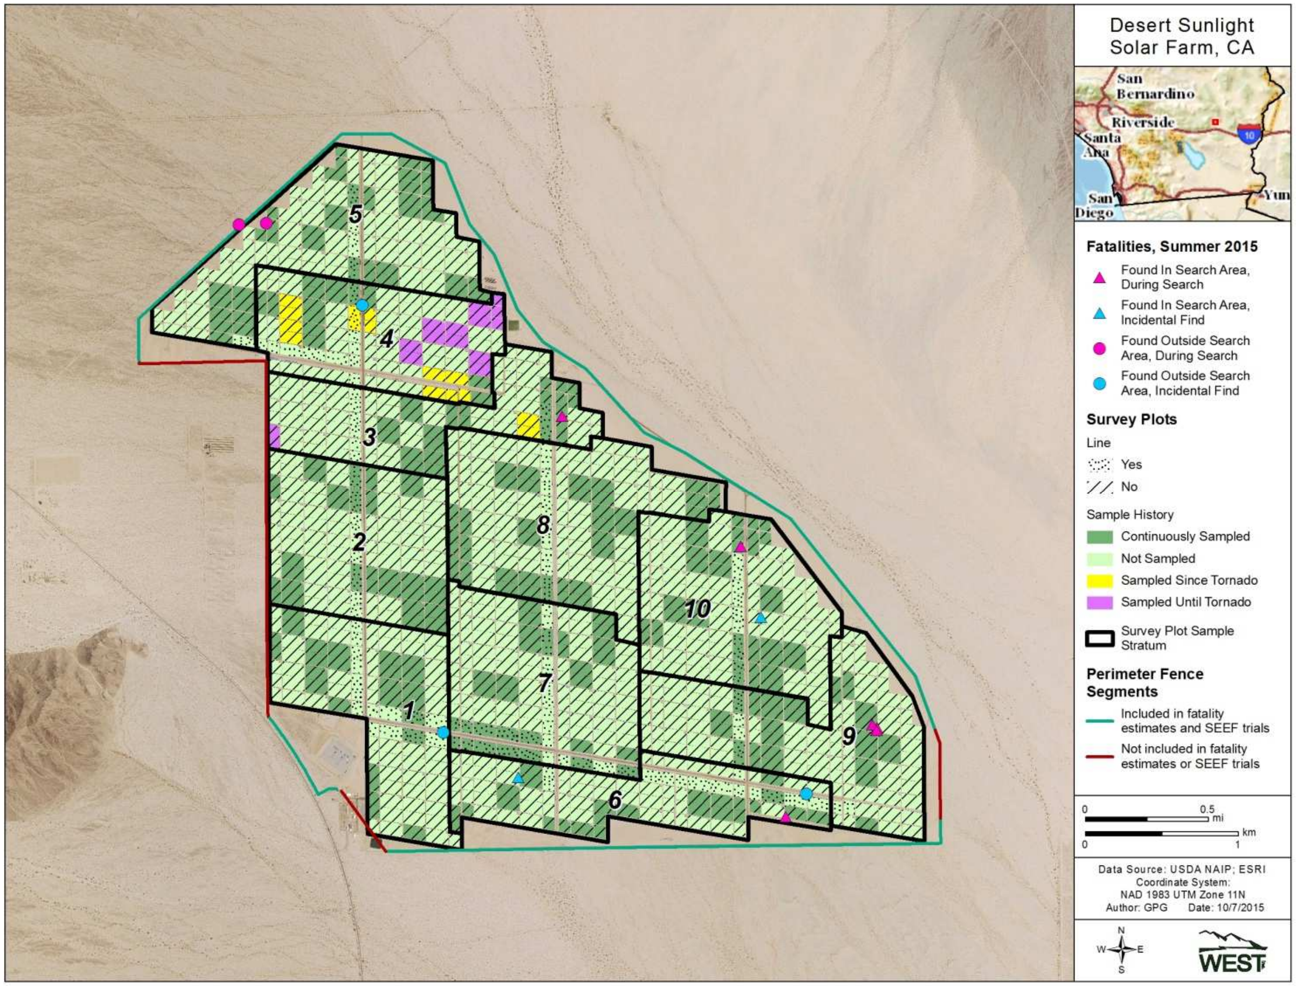

Figure 2. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance) at the solar field, fence, and overhead lines within the fence at Desert Sunlight Solar Farm Project during summer (June 01 – August 30) 2015.

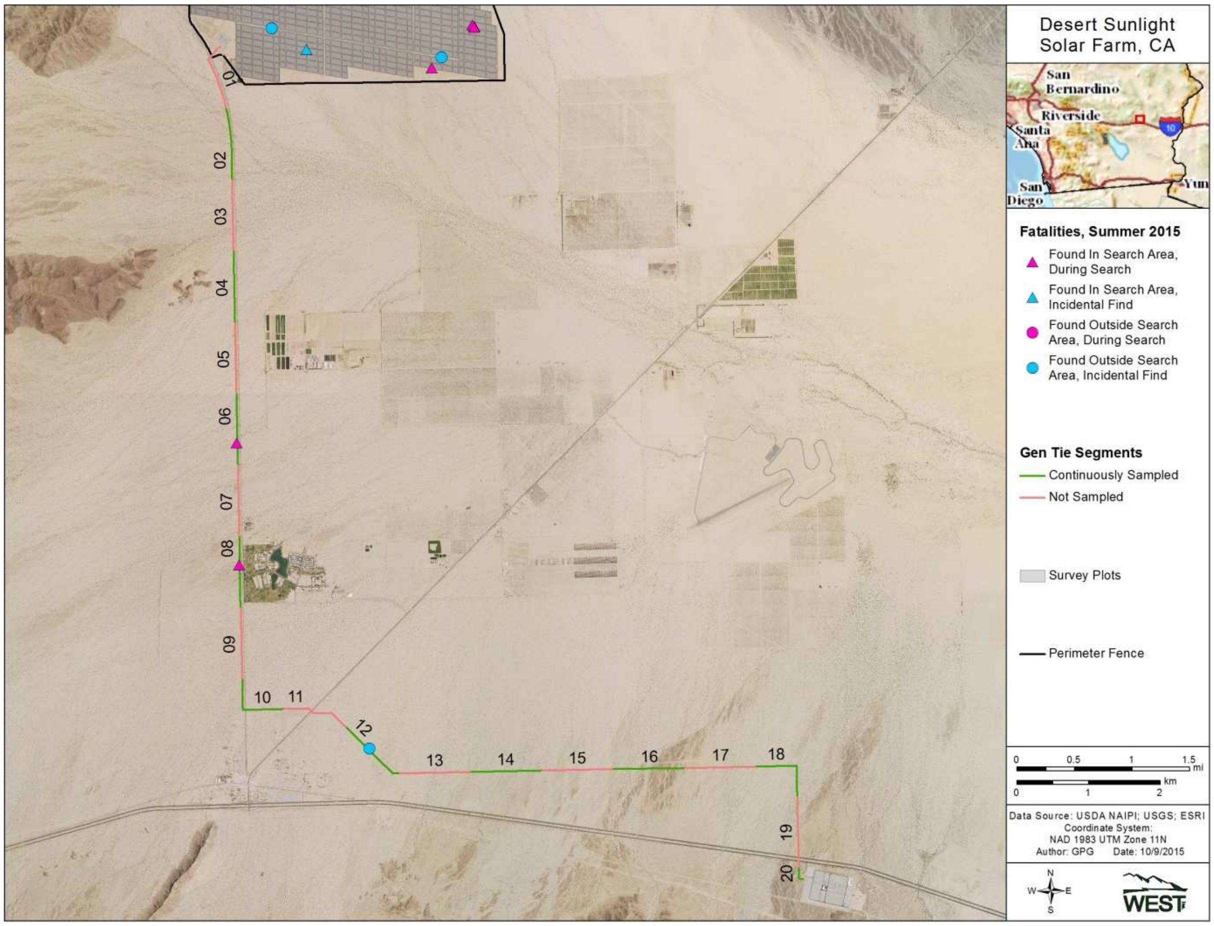

Figure 3. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance activities) along the generation tie line at the Desert Sunlight Solar Farm Project during summer (June 01 – August 30) 2015. Detailed maps of detections along the line are presented in Appendix A.

To ensure a balanced distribution of sample units in the solar field (defined as the collection of all photovoltaic [PV] solar panels), the entire field was divided into ten strata, and individual sampling units were randomly selected within each stratum to compose an approximately 30% sample. This sampling design ensures that units included in the sample were not spatially clumped within the solar field. The solar field consists of arrays of solar panels (referred to as a solar array) that are either 70-m or 140-m wide. The sample includes 133 of each type of array. There are 2,580 70-m rows, and 3,900 140-m rows in the sample.

2.1.1 *Search Frequency and Timing*

Standardized searches occurred during the summer survey season, which includes the period from June 01 through August 30, 2015. All project components included in standardized searches were surveyed four times during summer. All searches took place during daylight hours from 06:30 to 17:00.

As specified in the approved Desert Sunlight BBCS, the average search interval for all Project components included in standardized carcass searches during summer was 21.0 days (median 21.0 days). Slight variation in search interval was anticipated due to weather and logistical delays.

Table 2. Area and proportion of solar arrays that are and are not associated with overhead lines at the Desert Sunlight Solar Farm Project, Riverside County, CA.

	Line-associated[1]	Not line-associated	Proportion line-associated
Entire facility	89.4 ha	956.5 ha	0.09
Standardized searches	32.2 ha	291.0 ha	0.10

[1] Line-associated area was estimated as the area of any array that fell within the 30-m strip transect below the MVOH.

2.1.2 *Search Methods*

Standardized carcass searches were performed by BLM-approved biologists, in accordance with methods outlined in the BBCS.

Within the solar field, arrays of solar panels were surveyed by observers traveling on foot. A distance sampling approach was used, whereby biologists slowly walked a transect line along the ends of rows of solar panels in a direction perpendicular to the rows, searching ahead and to the side within the array for bird and bat detections. Biologists scanned out to a maximum perpendicular distance of approximately 70 m from the transect. Biologists carried binoculars to allow them to verify the presence of a detection versus rocks or vegetation. Once a detection was confirmed, the distance of the detection to the transect line was estimated using laser range finders. Each array included in the sample was searched by observers walking two transects – one on the west side and one on the east side of the array with observers looking toward the center of the array.

Once a carcass was detected, it was photographed, and data were recorded according to specifications outlined in section 7.2.5 of the approved Desert Sunlight BBCS. Carcasses were then retrieved from their location on the ground, labeled, and placed in a freezer on site.

Most (74.4%) of the length of fenceline (approximately 10 miles) was searched from a vehicle using the standard protocol (Figure 2). Biologists searched a 6-m wide strip transect centered on the fence from the inner perimeter. Travel speed was below five miles per hour (mph) while searching. Some sections along the fence cannot be driven close to the fence line. The fence line along the western edge of the Project is drivable but the road is approximately 15 m away from the fence and the road and fence are separated by a drainage ditch. The fence along this section is covered with a tan tarp and trees and shrubs have been planted to reduce visibility of the project from the west. Additions of vegetation and the tarp likely reduce potential for bird collision with the fence. This section of the fence was driven to document carcasses, but detections along this portion of the fence are not included in adjusted fatality estimates because detection rates are likely very low. As specified in section 4.2.6 in the approved Desert Sunlight BBCS, we assume that fatality rates are similar between the portion of fence that was searched and the portion that was not. A separate section of the fence in the southeastern corner of the Project cannot be driven because the eastern edge of the berm that bounded construction ponds is too narrow for a vehicle. Along this portion of the fence, the observer stopped at both north and south ends of the berm and used binoculars to search for carcasses. Finally, the road along a portion of the southwest fence line near the entrance gate is approximately 30 to 50 m from the road and is separated from the fence by an area that has recently undergone vegetation restoration. This area was eliminated from sampling. Fatality rates estimated for sections of the fence that were sampled were adjusted to account for the proportion of fence not sampled with the standard monitoring protocol, as specified in section 4.2.6 of the approved Desert Sunlight BBCS.

The gen-tie line was searched using a 30-m wide strip transect (i.e., 15 m of ground on either side of the overhead line). Sample units along the gen-tie line were chosen by dividing the total length of line from the Project fence south to the Red Bluff Substation just south of I-10 into 1-km segments. Thus, a 47.9% sample of the total length of the line was searched (Figure 3). Biologists slowly walked every other 1-km segment of the line, meandering the width of the strip transect, scanning for dead or injured birds or bats within 15 m (49.2 ft) of the overhead line.

For each detection, a suspected cause of death or injury was assigned based on evidence available from the detection, evidence available on Project infrastructure, and proximity of the detection to Project infrastructure. Detections that had evidence of scavenging and lacked evidence on Project infrastructure were assigned as “unknown” because it cannot be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) had a suspected cause of death attributed to the respective Project component. However, it should be noted that there is substantial uncertainty associated with cause of death assignments because no events were directly observed. Detections assigned to the “unknown” category were included in fatality estimates if they were located within standardized carcass search areas, and all detections made during the summer season are reported here.

2.2 Carcass Persistence Trials

Carcass persistence trials were conducted throughout the summer period. Carcasses from three size classes (small [0-100 g], medium [101-999], and large [1000+ g]) were used for trials. The small size class comprised house sparrows (*Passer domesticus*) and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons (*Columba livia*), chukar (*Alectoris chukar*), and older coturnix quail, and the large size class comprised hen mallard (*Anas platyrhynchos*) and hen ring-necked pheasant (*Phasianus colchicus*).

2.2.1 *Carcass Persistence Data Collection*

To quantify carcass persistence rates, 15 small, 10 medium, and 5 large carcasses were randomly placed and monitored along the gen-tie line during summer 2015. Within the solar arrays and along the perimeter fence, the same numbers of each size category were placed, for a total of 60 carcass persistence trials at Desert Sunlight during the summer season, as specified in the approved Desert Sunlight BBCS. By placing carcasses inside (within arrays and along inner perimeter of the fence) and outside (along the gen-tie) the project fence, the possibility that there are different carcass persistence rates inside and outside the project fence is accounted for. Fifteen carcasses within the Project fence (within solar arrays and along the fence) were monitored using motion-triggered digital trail cameras, while the remaining carcasses were visited on foot, for 30 days or until the carcass had deteriorated to a condition at which it would no longer qualify as a documentable fatality. No carcasses along the gen-tie line were monitored with cameras because of theft and vandalism concerns. Carcasses without trail cameras were visited and photographed once per day for the first four days, and then every three to five days until the end of the monitoring period. To avoid training scavengers to recognize cameras as “feeding stations”, trail cameras were installed five days before specimens were placed, and two fake cameras without bias trial carcasses were also placed within the Project fence and periodically moved to new locations within the fence. Periodic ground-based checking of carcasses with trail cameras also occurred to guard against misleading indicators of carcass removal, such as wind blowing the carcass out of the camera’s field of view. To minimize potential bias caused by scavenger swamping (Smallwood 2007, Smallwood et al. 2010), carcass-persistence specimens were distributed across the entire Project, not just in areas subject to standard searches, and trials were initiated in smaller numbers on three different dates throughout the summer season.

2.2.2 *Estimating Carcass Persistence Times*

Measurements of carcass persistence rates were subject to censoring. In this context, censoring refers to the instance when a value (e.g. days a carcass is present before being removed) may not be known exactly, but is known to be within a finite range. For example, suppose a carcass was checked on day 7 and was present, and was checked again on day 10, but was found to be missing. The exact time until removal is unknown; however, it is known that the carcass became unavailable at some point between 7 and 10 days. This carcass would be considered “interval censored”. Similarly, if a carcass lasts the entire 30-day trial period, that carcass is “right censored”— it is known that the carcass lasted at least 30 days, but it may have persisted longer. Because carcass persistence data were censored, persistence was analyzed using methods that can accommodate censored data and still produce unbiased estimates of the probability of persistence (Therneau 2015, Therneau and Grambsch 2000).

USGS-developed fatality estimator software (Huso et al 2012) was used to fit survival models to the censored carcass persistence data. The USGS software used to estimate carcass persistence calculates the period over which there is less than a 1% chance for a carcass to persist. The 'effective search interval' is defined as the shorter of the period during which there is less than a 1% probability that a carcass persists, and the actual search interval (Huso 2010). The probability of persistence is given for the effective search interval, and the probability that a carcass persists through the actual search interval is equal to p(persist through effective search interval) * effective search interval / actual search interval.

There were four distributions implemented in survival models used to estimate the probability a carcass is unscavenged and available to be found at the end of the search interval (*r)*: exponential, Weibull, loglogistic, and lognormal. These four distributions exhibit varying degrees of flexibility in order to model a wide variety of distributions of persistence time. Akaike's Information Criterion adjusted for sample size (AICc; Akaike 1973) was used to rank the fit of each survival model with combinations of the covariates carcass size, Project component, season, and visibility, to observed carcass persistence data.

2.3 Searcher Efficiency Trials

Searcher efficiency trials were conducted throughout the summer period. Carcasses from three size classes (small, medium, and large) were used for trials. The small size class comprised house sparrows and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons, chukar, and older coturnix quail, and the large size class comprised hen mallards and hen ring-necked pheasants.

2.3.1 *Searcher Efficiency Data Collection*

Training of biologists on the Project-specific protocol and early assessments of habitat conditions within the solar arrays suggested that the amount of cobble present in the soil may be an important factor influencing searcher efficiency. To satisfy requirements regarding consideration of visibility class per the BBCS and address the influence of cobble cover on searcher efficiency, sample units in the solar arrays and along the gen-tie were stratified by cobble cover and assigned to one of two classes (<15% and >15% cobble cover). Classes were determined by making ocular estimates of cobble cover at each sample unit and then evaluating the frequency histogram of sample units across the range of estimated cobble cover (Figure 4). A natural break point was identified at 15% cobble cover, so the same value was chosen as the break point that defined the two cobble cover classes. Thus, in the solar arrays, two sets of searcher efficiency trials were conducted (one set in each cobble cover class; *n* for each trial = 15 small birds, 10 medium birds, and 5 large birds as agreed upon in section 7.4 of the approved Desert Sunlight BBCS). Along the gen-tie, visibility was expected to be related to vegetation and rock cover. Thus, searcher efficiency trials along the gen-tie occurred in two visibility classes (*n* for each class = 15 small birds, 10 medium birds, and 5 large birds (easy: ≥90% bare ground, vegetation <6" tall; and more difficult: <90% bare ground, vegetation ≥6" tall). Inadvertently, one large carcass was not placed and one extra small carcass was placed during summer, so total sample size for large carcasses along the gen-tie was nine, and for small carcasses was 31. Thirty searcher efficiency trials (*n* = 15 small birds, 10 medium birds, and 5 large birds) occurred along the fence in the only visibility class present on the fence (easy visibility). Thus, during summer, a total of 150 searcher efficiency trials occurred at the Project. Locations for trials were chosen by taking a randomized sample of all locations included in standardized carcass searches.

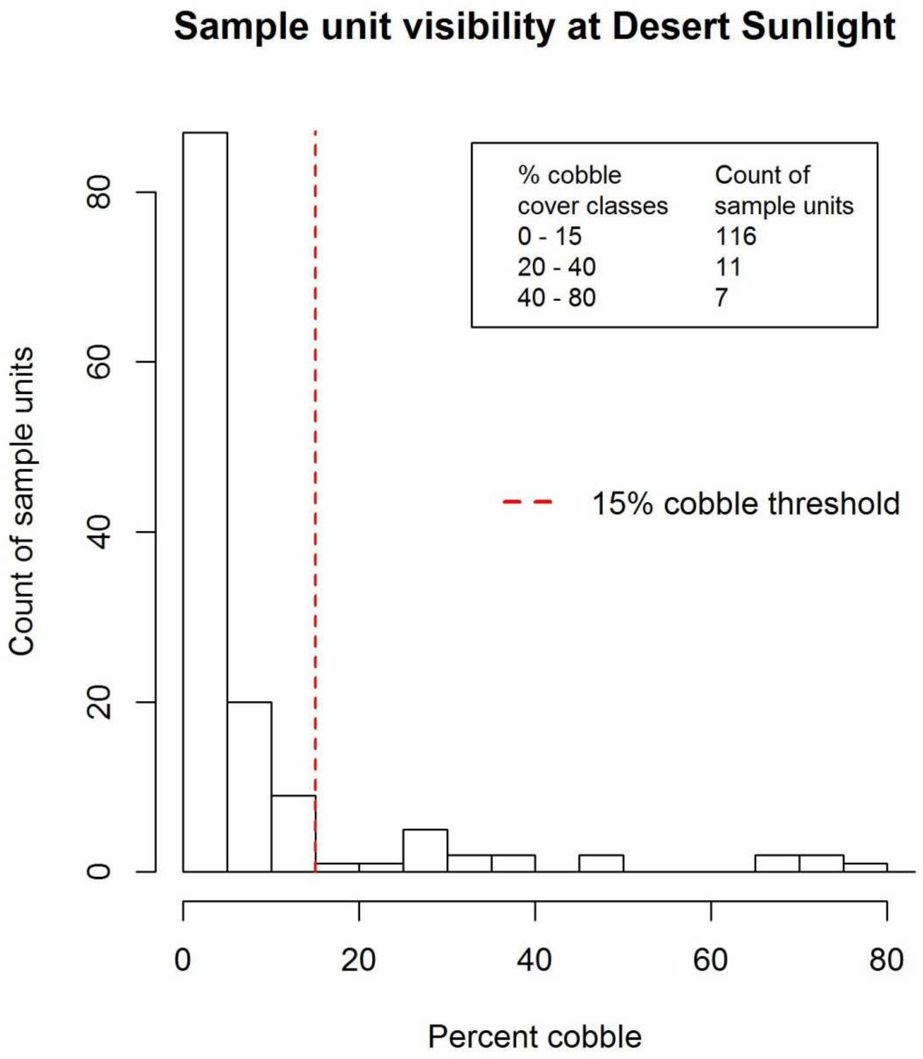

Figure 4. Frequency histogram of sample units (in the arrays only) at Desert Sunlight Solar Farm Project by estimates of cobble cover. Based on this distribution, each sample unit was assigned to one of two classes of cobble cover (<15%; >15%).

2.3.2 *Estimating Searcher Efficiency*

Searcher efficiency at Desert Sunlight was estimated separately for linear features (the project fence and the generation tie line), and the solar arrays, reflecting the different search methods used on arrays and linear features. For linear features, logistic regression models were fit to searcher efficiency data and AICc was used to compare models. Models including effects of carcass size (three classes), visibility (two classes; gen-tie only), and season were compared to each other and the null model. Model selection indicated that the best model included main effects of Project component, carcass size, and season. Once the best model was chosen and appropriate classes identified, searcher efficiency, or the proportion of carcasses detected, *p*, was calculated for each class using the following equation:

$$p = \frac{Number\ of\ Carcasses\ Observed}{Number\ of\ Carcasses\ Available}$$

The data for this analysis included all searcher efficiency trial carcasses from the summer 2015 season.

For the solar arrays, searcher efficiency was evaluated using a distance sampling approach (Buckland et al. 1993). Distance sampling assumes perfect detection on the transect line (at distance = 0), an assumption that is likely valid in the solar arrays given the relatively flat & vegetation-free nature of the soil surface. A curve is fitted to the observed carcass data that predicts probability of detection as a function of distance from the transect line. The mean value of this function over a specified distance, *w,* is equal to the average searcher efficiency for a transect of width *w*. The mean value of the detection curve is the integral of the detection function calculated between 0-m and the maximum survey distance (*w;* half the width of the solar array row), divided by the maximum survey distance:

$$p = \frac{\int_0^w f(x)dx}{w},$$

where f(x) is the detection function evaluated at distance, *x*.

One departure in the methods used here, relative to the methods presented in Buckland et al. (1993), was that for this study the detection function was estimated using trial carcasses, which meant that there were both presence (detected) and absence (not detected) data available to fit the detection function (Figure 5). The availability of both presence and absence data means that the detection function can be estimated using only trial carcasses whose distribution is known. Therefore the detection function, the average searcher efficiency among the arrays and the final fatality estimate within the arrays are all insensitive to the spatial distribution of carcasses within individual arrays, and the overall searcher efficiency estimate is valid even if the distribution of carcasses among the arrays is not uniform.

Distances of trial carcasses (trials both found and missed) from the transect line were used to fit a half-normal detection function for searches among the arrays (Figure 5). The half-normal detection function is a commonly used function for distance sampling surveys (Buckland et al. 1993). The detection function was fit with and without covariates (carcass size, visibility index, or no covariates) and AICc indicated that the best among these models included only carcass size as a covariate.

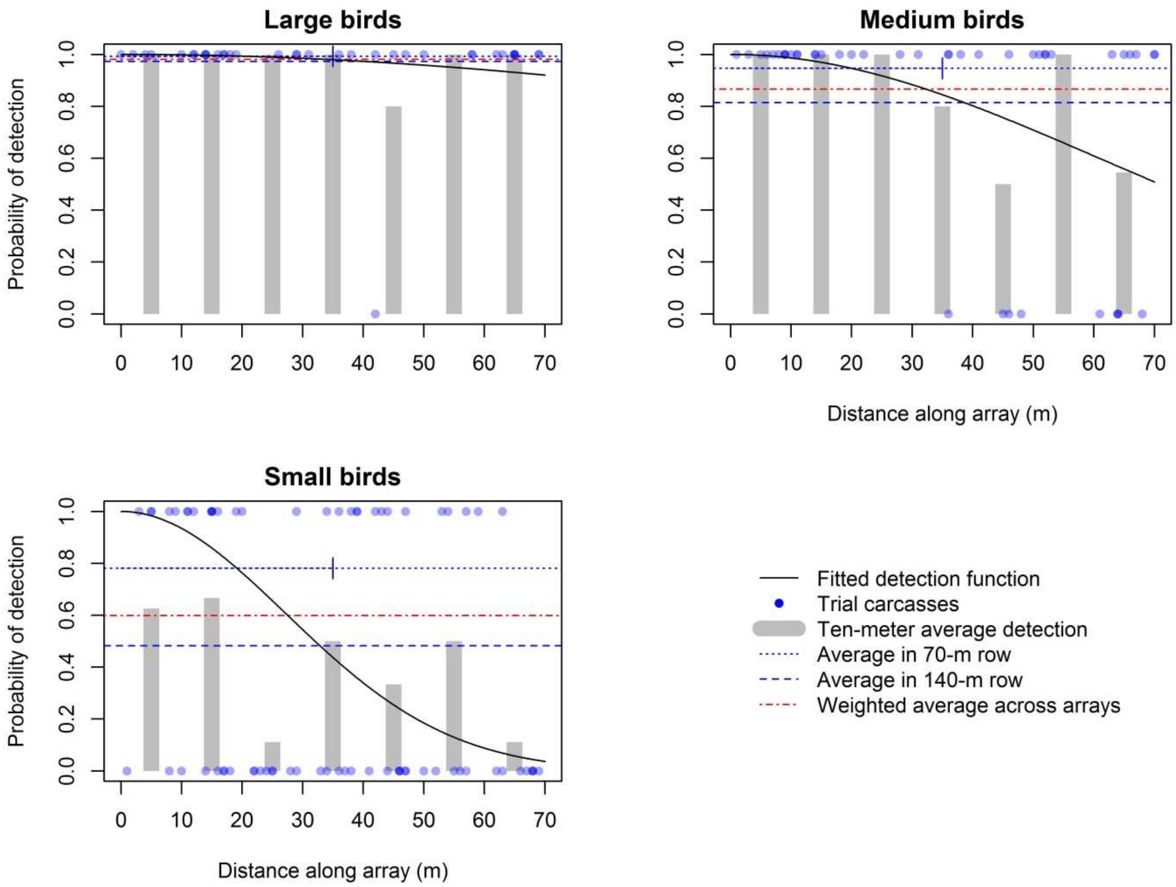

Figure 5. Estimated detection probabilities for bird carcasses by size class during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California. Distance sampling was used when searching solar arrays only. Average probability of detection over 70-m (arrays relying on a 35-m viewshed) and 140-m (arrays relying on a 70-m viewshed) panel rows in solar arrays are presented.

Because the solar arrays were surveyed by searchers who walked down both sides of the rows of panels, the width of the search transect was specified as half the width of the rows of panels. For larger birds, there is almost certainly a non-zero detection probability beyond this distance but the bias that occurs by ignoring this non-zero detection probability is conservative (i.e. the searcher efficiency is underestimated). Some solar arrays have row widths of 70 m (search transect width of 35 m) and some have row widths of 140 m (search transect width of 70 m). The weighted average searcher efficiency is calculated based on the number of panel rows of each length in the survey sample:

$$p_{weighted\ average} = \frac{n_{70}}{n} \times \int_0^{35} f(x)dx + \frac{n_{140}}{n} \times \int_0^{70} f(x)dx,$$

where n_{70} is the number of 70-m rows in the sample, n_{140} is the number of 140-m rows in the sample, and n is the total number of rows in the sample. Searcher efficiency was higher for the arrays with a width of 70 m, and overall searcher efficiency was estimated as a weighted average based on the proportions of 70-m arrays and 140-m arrays in the sample units.

2.4 Fatality Estimator

Fatality rate estimation is a complex task due to several variables inherent to every fatality monitoring study. Carcasses may persist for variable amounts of time due to local scavenger activity or environmental conditions leading to carcass degradation over time. Carcasses and feather spots are also detected with varying levels of success based on carcass characteristics and ground cover (e.g., vegetated areas underneath the gen-tie line versus cleared areas beneath solar panels). For these reasons, it is generally inappropriate to draw conclusions based on the raw number of fatalities alone. The desire to estimate fatalities given these variables has driven the development of several statistical methods for estimating fatalities (e.g., Smallwood 2007, Huso 2010, Korner-Nievergelt 2011). All of these fatality estimation methods share a similar underlying model. Generally, the fatality estimation for a given site may be written as:

$$F=C/rp,$$

where F is the total number of fatalities, C is the number fatalities detected and included in fatality estimation, r is the probability a carcass is unscavenged and available to be found at the end of the search interval, and p is the probability of detecting a carcass (Huso 2010).

All fatality estimates were calculated using the Huso estimator, as well as 90% confidence using bootstrapping (Manly 1997). Bootstrapping is a computer simulation technique that is useful for calculating point estimates, variances, and confidence intervals for complicated test statistics. A total of 1,000 bootstrap replicates were used. The lower 5th and upper 95th percentiles of the 1,000 bootstrap estimates provide estimates of the lower limit and upper limit of an approximate 90% confidence interval on all estimates.

2.5 Incidental Reporting

Some detections were outside standardized search areas, or were within search areas but not observed during standardized searches. Such detections were found by WEST avian biologists and operational personnel and were considered “incidental” detections. When found by operational personnel, these detections were reported to WEST avian biologists for documentation. Data on incidental detections are reported here, as well as in the Desert Sunlight SPUT Avian Injury and Mortality Report Forms June – August 2015. All detections made in search areas during the reporting period were included in fatality estimates, regardless of whether they were detected incidentally or during searches.

3.0 MONITORING RESULTS

3.1 Summary of Avian Detections

During summer 2015, a total of 15 avian detections (including incidentals) of 11 identified species were recorded (Table 3). The most common identified species was common raven (*Corvus corax*) with three detections. Most detections (n = 11, or 73.3% of total detections) occurred in the solar arrays (Figures 2 and 3; Tables 4, 5, and 6). Ten (66.7%) detections were made during standardized carcass searches and five (33.3%) were documented as incidentals. No bats were detected during the summer season. For fresh carcasses, body weights and weather conditions the preceding nights are described in Appendix B.

Table 3. Number of individual bird detections, by species, during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California. LA = line-associated; NLA = non-line associated.

Common Name	Scientific Name	Migration Behavior*	Guild	LA Solar Array	NLA Solar Array	Fence	Gen-tie Line	Total
common raven	*Corvus corax*	resident	Corvids	-	2	1	-	3
white-winged dove	*Zenaida asiatica*	variable	Doves/Pigeons	-	-	-	1	1
black-throated sparrow	*Amphispiza bilineata*	diurnal	Grassland/ Sparrows	-	-	-	1	1
sora	*Porzana carolina*	nocturnal	Rails/Coots	-	-	-	1	1
Virginia rail	*Rallus limicola*	nocturnal	Rails/Coots	1	-	-	-	1
house wren	*Troglodytes aedon*	nocturnal	Wrens	1	-	-	-	1
mourning dove	*Zenaida macroura*	variable	Doves/Pigeons	-	1	-	-	1
Say's phoebe	*Sayornis saya*	diurnal	Flycatchers	-	1	-	-	1
northern rough-winged swallow	*Stelgidopteryx serripennis*	diurnal	Swallows	-	1	-	-	1
unidentified bird (small)	-	-	Unidentified Birds	-	1	-	-	1
unidentified bird (unknown size)	-	-	Unidentified Birds	-	1	-	-	1
unidentified grebe	-	-	Waterbirds/ Waterfowl	-	1	-	-	1
western grebe	*Aechmophorus occidentalis*	nocturnal	Waterbirds/ Waterfowl	-	1	-	-	1
Total				**2**	**9**	**1**	**3**	**15**

* See literature cited for migration behavior references; information for most species was taken from the respective species accounts found in Birds of North America (BNA) Online (http://bna.birds.cornell.edu/bna/); where information on migration behavior was lacking in BNA accounts, Newton (2008) or Murray (2004) were used.

Table 4. Total avian detections by Project component and detection category during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California. Only carcasses found within search areas were included in fatality estimates.

	Inside carcass search area		Outside carcass search area	
Project Component	**Carcass search**	**Incidental**	**Carcass search**	**Incidental**
Fence	0	0	1	0
O&M Building	0	0	0	0
Gen-tie line	2	0	0	1
Solar arrays				
Line-associated	0	0	0	2
Non-line associated	7	1	0	1

Table 5. Total avian detections (including incidentals) by Project component and suspected cause of death during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California.

	Suspected Cause of Death*				
Project Component	**Collision**	**Predation**	**Other**	**Unknown**	**Percent of Total**
Fence	0	0	1	0	6.7
O&M building	0	0	0	0	0
Gen-tie line	2	0	1	0	20
Solar arrays					
Line-associated	1	0	1	0	13.3
Non-line associated	1	0	5	3	60
Percent of Total	**26.7**	**0**	**53.3**	**20.0**	**100.0**

* Suspected cause of death was assigned based on evidence available on the detection, evidence available on Project infrastructure, and proximity of detection to Project infrastructure. Detections that had evidence of scavenging and lacked evidence on Project infrastructure were assigned as "unknown" because it can't be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) had a suspected cause of death attributed to the respective Project component. However, there is substantial uncertainy associated with cause of death assignments because no events were directly observed.

3.2 Temporal Patterns of Avian Detections

The number of detections recorded daily during the reporting period ranged from zero to three (Figure 6). One detection was found per day with the exception of June 24 when three detections occurred. The number of detections per day represents those discovered during standardized carcass searches and incidentally.

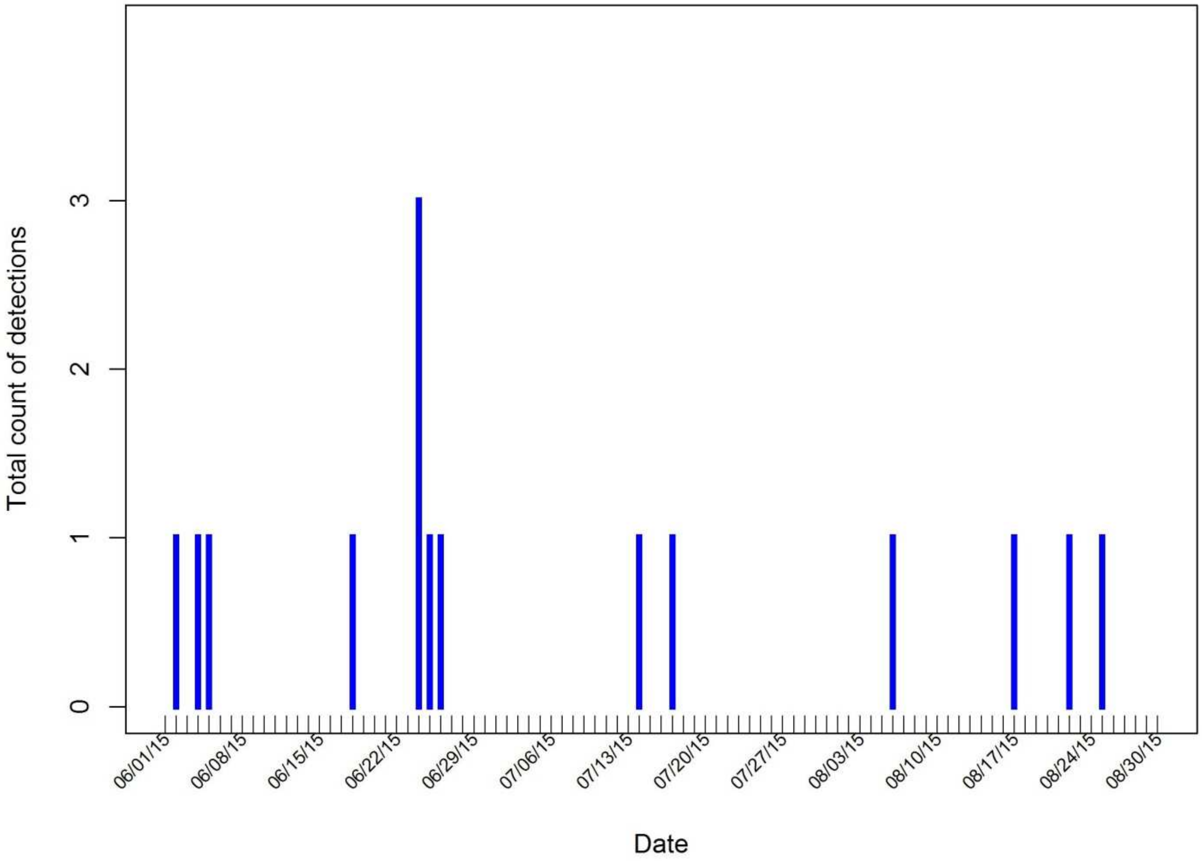

Figure 6. Total number of detections by date during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California.

3.3 Spatial Distribution of Avian Detections

3.3.1 *Detections by Project Component*

During the reporting period, detections were documented from the solar arrays, the northern section of the perimeter fence, and the gen-tie line; no detections occurred at the O&M building (Tables 3, 4, and 5). Of the 11 detections within the solar arrays, 18.2% (2) were associated either with overhead lines or arrays that co-occurred with overhead lines.

3.3.2 *Feather Spot Detections*

Five (33.3%) of the 15 detections consisted only of feather spots. Along the gen-tie, one of three detections (33.3%) was a feather spot. No detections along the fence were a feather spot. Four of 11 detections (36.4%) in the solar arrays were feather spots.

3.4 Detections of Injured Birds

No injured birds were detected during the summer 2015 season.

3.5 Summary of Bat Detections

No bats were detected during the summer 2015 season.

3.6 Carcass Persistence Trials

Data from carcass persistence trials were available from late winter, spring, and summer at the solar field and gen-tie line (n = 154 total). Based on carcass persistence data from late winter, spring, and summer 2015, survival models were compared for relative quality using the corrected AICc score, as suggested in Huso (2010). The AICc score provides a relative measure of model fit and parsimony among a selection of candidate models, and provides a framework for testing hypotheses regarding which factors contribute to carcass persistence rates. Carcass size was tested as a potentially important variable, as larger carcasses tend to persist longer and may be more likely to leave feather spots which persist for long durations, whereas smaller carcasses may be more likely to be completely removed. Project component (solar arrays/fence, generation-tie line) was also included as a potentially important variable, as was season.

The model with lowest AICc score is typically chosen as the “best” model relative to other models tested; however, any model within two AICc points of the best model is considered competitive with the best model (Burnham and Anderson 2004). The best model included main effects of season, carcass size, Project component, and interactions of Project component × season and Project component × size with a Weibull-distributed removal time. Given the main effect of season, further modeling efforts were restricted to data collected in summer only. The best model using only the summer data suggested an interaction between carcass size and Project component. Estimates of carcass removal time and persistence probabilities are reported in Table 6 from the best model, and estimates of proportion of carcasses remaining as a function of days since carcass placement are provided in Figure 7.

Table 6. Mean carcass removal time and probability of a carcass persisting through the effective search interval during the summer season (June 01 – August 30) at the Desert Sunlight Solar Farm Project, Riverside County, California.

Carcass size	Project component	Mean removal time (days)	Probability of persistence
Small	Arrays/fence	15.53	0.63
Small	Overhead lines	1.37	0.22
Medium	Arrays/fence	19.2	0.73
Medium	Overhead lines	14.75	0.60
Large	Arrays/fence	-*	1.00
Large	Overhead lines	0.9	0.22

* Mean removal time was not estimated because no removal was observed for large carcasses within the solar field.

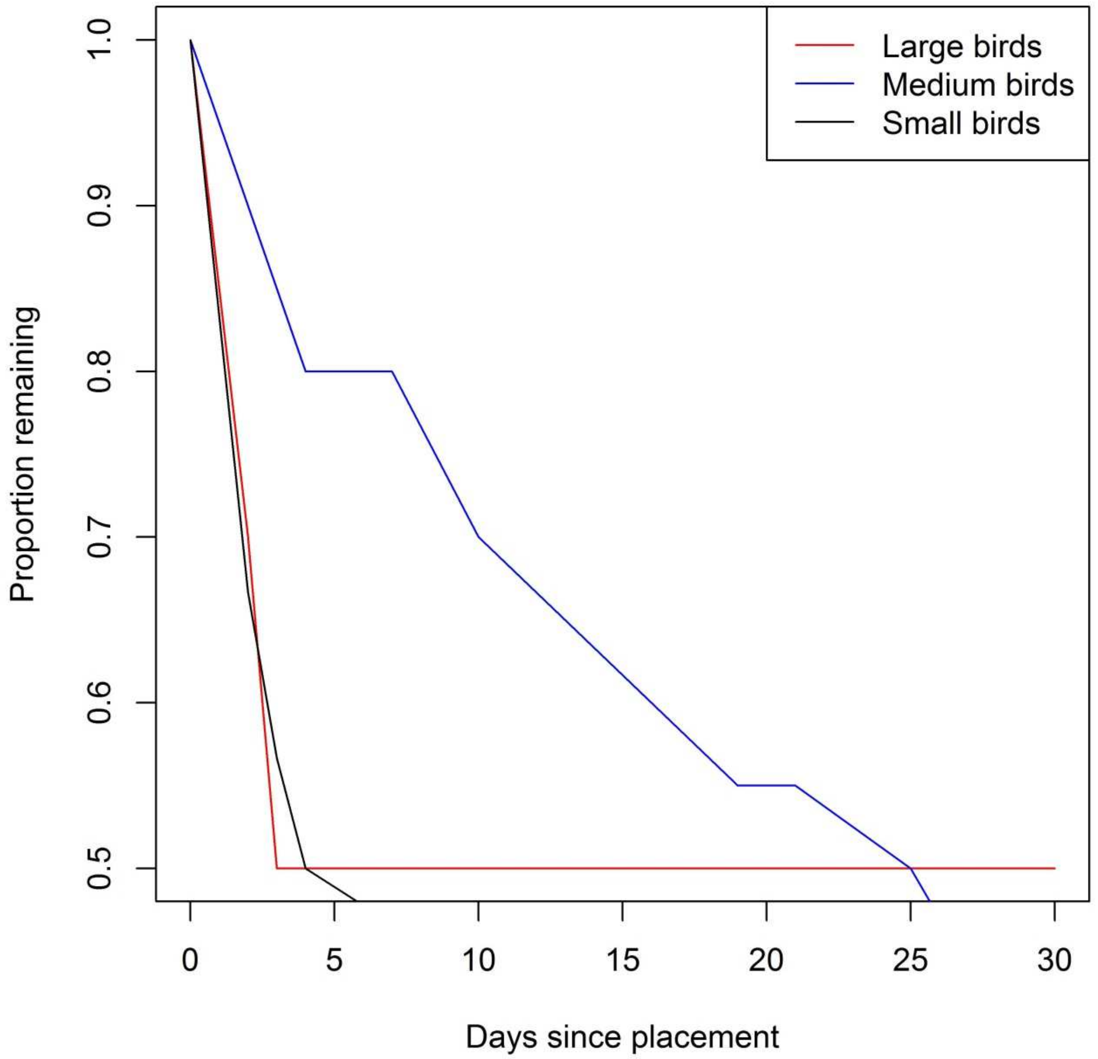

Figure 7. Proportion of trial carcasses remaining as a function of days since placement and carcass size class (n = 30, 20, and 10 for small, medium, and large size classes, respectively) during the summer (June 01 – August 30) 2015 season at the Desert Sunlight Solar Farm Project, Riverside County, California.

3.7 Searcher Efficiency Trials

During the reporting period, a total of 150 searcher efficiency trials were placed at the Project. Most trials were available to be found, but some disappeared before or during the trial. Overall, 60 trials were placed in the solar arrays and 44 were available to be found; 30 trials were placed along the perimeter fence (inner perimeter only) and 30 were available to be found; and 60 trials were placed along the gen-tie line and 55 were available to be found.

In the solar arrays, the model that included an effect of carcass size was chosen as the best model to estimate searcher efficiency. Within the solar arrays, searcher efficiency was: 60.0% for small birds, 86.6% for medium birds, and 98.1% for large birds (Figure 5).

For linear Project components, the model that included an effect of carcass size, Project component, and season was chosen as the best model to estimate searcher efficiency. Along the fence, searcher efficiency ranged from 87.5% to 100% depending on carcass size class. Along overhead lines, searcher efficiency ranged from 43.5% to 100%. Detailed estimates of searcher efficiency estimates specific to each component and carcass size are reported in Appendix C.

3.8 Fatality Estimates

Fatality estimates were calculated separately for each component (solar arrays, fence, and overhead lines). Ultimately, five detections were excluded from the fatality analysis because they were found outside standardized search areas. All 15 detections made during summer are reported in Table 3.

During summer 2015, there were an estimated total 148 carcasses (90% CI: 10 – 365) at the Project. Of these, 44 carcasses (27.5%; 90% CI: 8 – 64) were estimated for the solar arrays and 104 carcasses (66.9%; 90% CI: 2 – 339) were estimated for the gen-tie line. While we are required to report the gen-tie estimates per the approved BBCS, these estimates are not reliable due to the high rates of scavenging that were observed during the limited trials at the gen-tie and the low number of carcasses detected (n = 2 in the fatality analysis). No carcasses were estimated for the perimeter fenceline because there were no detections made along the fence. All of these estimates should be interpreted with caution because variance estimates are in general unreliable when carcass counts are low (< 5 per category). Other projects (e.g. Ivanpah) are not reporting estimates when carcass counts are less than or equal to five. However, the TAG has asked for both the estimates and confidence intervals for this project with the appropriate caveat added. There were an estimated 0.017 fatalities per acre (within the solar field only; 44 estimated carcasses/2,585 acres) and an estimated 0.08 fatalities per nameplate MW (44 estimated carcasses/550 MW) within the solar field. A complete list of estimates for each Project component and carcass size class with confidence intervals is presented in Appendix C.

4.0 DISCUSSION

The 2015 summer season represented the second full season of standardized monitoring at Desert Sunlight per the BBCS. Searcher efficiency trials and carcass removal trials were conducted concurrently at the solar arrays, fencelines, and along the gen-tie line. Data from these trials were used to produce fatality estimates adjusted for searcher efficiency and carcass persistence bias. Although these estimates were produced from a statistically robust sample, only limited inference may be drawn from two seasons of data. These results should be considered preliminary because estimating carcass persistence, searcher efficiency, and adjusted numbers of fatalities within each season represents information based on a limited sample size. As more data are collected throughout the monitoring year (and additional quality assurance/quality control measures occur, for example characterizing feather spots to species or size class), data from all seasons may be pooled. At that time, data will be tested for seasonal differences retrospectively, but because seasonal estimates will be produced from the much larger annual data set, they may differ from what is reported here because they are based on a larger, more informative sample.

4.1 Carcass Persistence and Searcher Efficiency Trials

The degree to which carcasses persist on the landscape depends on a variety of factors reflecting seasonal and inter-annual variation in habitat, climate, and the scavenger community. The composition and activity patterns of the scavenger community often vary seasonally as birds migrate, new juvenile birds and mammals join the local population, and mammalian scavengers variably hibernate or estivate. The scavenger community may also vary substantially from year to year because of variation in annual reproduction and survival related to changes in landscape condition. Climatic conditions that vary seasonally and annually also may contribute to variation in carcass decay and removal rates due to variation in temperatures, solar insolation, wind patterns, and the frequency of flooding events. Thus, rates of carcass persistence reported here should be interpreted cautiously as they may change over the coming months.

Searcher efficiency was influenced by Project component, carcass size, and season. In the solar arrays, searcher efficiency was high (> 0.5) for all carcass size classes and this is likely influenced by the limited vegetation cover beneath solar panels. Beneath the gen-tie line, vegetation cover is higher in some portions of the strip transects, but results reported here support the hypothesis that visibility class is not a factor in searcher efficiency along the lines during summer.

For the current analysis, searcher efficiency in the solar arrays was assumed to be best predicted by a half-normal distribution. For future analyses, AICc will be used to compare and choose the best among multiple detection functions.

4.2 Distribution of Fatalities and Fatality Estimates

The number of detections was more or less evenly distributed across the summer season, and there were no clear associations between number of detections and date. Given the small number of detections overall, it is premature to draw any conclusions about the spatial distribution of carcasses.

Composition of detections during summer 2015 included eight avian guilds. Corvids comprised the majority of detections (n = 3): there were two detections each within the doves/pigeons, rails/coots, and waterbirds/waterfowl guilds. No bats have been detected since monitoring began at the Project.

Detections attributed to an unknown cause accounted for 20.0% of all detections during the reporting period, and all those attributed to an unknown cause were found in the solar arrays. Of the 11 detections made in the solar arrays, 36.4% were feather spots. Determining a cause of mortality from a feather spot is challenging because there is rarely visible evidence available on which to determine a cause of death. Thus, feather spots with an unknown cause of mortality could be encountered anywhere birds occur, and an unknown cause of a sizeable proportion of the carcasses is not unique to the Project. Further, the relatively large proportion of feather spots (33.3%) among the detections for the Project as a whole may inflate the fatality estimate when unknown cause detections are included based on the potential for multiple feather spots resulting from one fatality, feather spots resulting from predation not associated with the facility, or other causes.

EXECUTIVE SUMMARY

Avian and bat monitoring surveys were conducted from June 01 to August 30, 2015 (the reporting period) at Desert Sunlight Solar Farm Project (Project) in accordance with the Project's Bird and Bat Conservation Strategy (BBCS). For logistical reasons, fall monitoring began on Monday, August 31, 2015. Specifically, standardized carcass searches, searcher efficiency trials, and carcass persistence trials were conducted. This report represents the second seasonal report for the first year of monitoring, and summarizes monitoring methods and results for those surveys based on the procedures and requirements specified in the BBCS.

Included in this report are data from standardized carcass searches conducted during the summer season at the Project, defined as June 01 to August 30, 2015. Standardized carcass searches were conducted 1) in the solar field, consisting of a random stratified 29.5% sample of solar photovoltaic (PV) panels, 2) along inner portions of the fenceline, resulting in 74.4% of the length of the perimeter fence, and 3) along 47.9% of the total length of generation-tie (gen-tie) line from the Project fence to the Red Bluff Substation located south of Interstate 10 (I-10). Searches conducted within the summer season had intervals of approximately 21 days.

All bird and bat fatalities and injuries that were discovered by observers, referred to as "detections" in this report, including those found incidentally and during standardized carcass searches, were documented. During the reporting period, 15 avian detections were made, and there were no detections of bats.

According to specifications of the BBCS, avian detections were categorized by likely diurnal or nocturnal migration behavior, ecological guild (e.g., raptors, songbirds, etc.), facility component, and suspected cause of death. These standardized carcass search results, along with searcher efficiency and carcass persistence rates from bias trials conducted on site, were applied to a fatality estimator model (Huso 2010) to provide a preliminary estimate of the number of fatalities that occurred at the Project during the reporting period adjusted for sources of bias. The estimate is considered preliminary because the annual report may pool information from bias trials and other data across seasons which could affect seasonal estimates.

During the reporting period, carcass persistence was influenced by carcass size and Project component. Small carcasses (0-100 g) in the arrays and along the fence (combined) had a 63% chance (90% confidence interval [CI]: 48 – 76%) of persisting through the effective search interval, medium carcasses (101 – 999 g) had a 73% (55 – 86%) chance, and large carcasses (1000+ g) had a 100% chance because no removal was observed. Mean removal time within the arrays for small and medium carcasses was 15.5, and 19.2 days, respectively; mean removal time was not estimated for large carcasses because no removal was observed. Along the generation tie-line, chances of persistence for small, medium, and large carcasses were 22% (14 – 26%), 60% (37 – 74%), and 22% (14 – 26%), respectively; mean removal time for small, medium, and large carcasses was, 1.4, 14.8, and 0.9 days, respectively. Within the solar arrays, searcher efficiency was influenced by carcass size: 60.0% for small birds, 86.6% for

Comentado [FWS1]: Please explain why carcass persistence is influenced by project component.

Comentado [FWS2]: Please report median removal times and a figure showing the curve of # remaining over time.

Comentado [FWS3]: Is this the searcher efficiency averaged for all observers? What is n?

medium birds, and 98.1% for large birds. Along the fence, searcher efficiency ranged from 87.5% to 100% depending on carcass size class. Along the generation tie-line, searcher efficiency ranged from 43.5% to 100%.

Composition of detections during summer 2015 included eight avian guilds. Corvids comprised the majority of detections (n = 3): there were two detections each within the doves/pigeons, rails/coots, and waterbirds/waterfowl guilds. No bats have been detected since monitoring began at the Project.

Using the Huso (2010) fatality estimator model, during summer 2015, there were an estimated total 148 carcasses (90% CI: 10 – 365) at the Project. Of these, 44 carcasses (27.5%; 90% CI: 8 – 64) were estimated for the solar arrays and 104 carcasses (66.9%; 90% CI: 2 – 339) were estimated for the gen-tie line. While we are required to report the gen-tie estimates per the approved BBCS, these estimates are not reliable due to the high rates of scavenging that were observed during the limited trials at the gen-tie and the low number of carcasses detected (n = 2 in the fatality analysis). No carcasses were estimated for the perimeter fenceline because there were no detections made along the fence. All of these estimates should be interpreted with caution because variance estimates are in general unreliable when carcass counts are low (< 5 per category). ~~Other projects (e.g. Ivanpah) are not reporting estimates when carcass counts are less than or equal to five. However, t~~The TAG has asked for both the estimates and confidence intervals for this project with the appropriate caveat added. There were an estimated 0.017 fatalities per acre (within the solar field only; 44 estimated carcasses/2,585 acres) and an estimated 0.08 fatalities per nameplate MW (44 estimated carcasses/550 MW) within the solar field.

Comentado [FWS4]: IMPORTANT: WEST has said that it modified the Huso estimator, and despite several requests, those modifications have not been shared with the agencies. Until we understand what changes to the code were made, we are reserving judgment on these results.

Comentado [FWS5]: This supports increased frequency for this component.

Comentado [FWS6]: Is this relevant? Please delete.

All projects are reporting all mortalities via SPUT reporting regardless of how many.

1.0 INTRODUCTION

1.1 Project Background

Desert Sunlight 250, LLC and Desert Sunlight 300, LLC (collectively, Desert Sunlight) constructed and operates the Desert Sunlight Solar Farm Project (referred to in this report as "Project"), which consists of two main components: 1) a 550-megawatt (MW) photovoltaic (PV) generating facility; and 2) a 220-kilovolt (kV) generation interconnection (gen-tie) line. The Project comprises approximately 1,700 hectares (ha; 4,200 acres) of land administered by the Bureau of Land Management (BLM) six miles north of Desert Center in Riverside County, California (Figure 1).

1.2 Monitoring Plan Overview and Goals

A Bird and Bat Conservation Strategy (2014; “BBCS”) was prepared by the Project proponent in collaboration with the U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), and BLM to guide comprehensive monitoring of impacts to birds and bats associated with operation of the Project. Final agency approval of the BBCS occurred in December 2014. Amendments to the sampling protocol along some portions of the Project fenceline were made by Desert Sunlight and approved by the BLM on February 11, 2015.

The BBCS details post-construction monitoring to be conducted and the data analysis and reporting processes that will be implemented by Desert Sunlight in collaboration with the USFWS, CDFW, and BLM. As identified in the BBCS, they are:

1. Estimate overall annual avian fatality rate and species composition associated with the Project infrastructure. This estimate will include mortality associated with solar arrays, overhead lines including the gen-tie line, perimeter fence and other features of the Project that may result in injury and fatality.
2. Determine whether there are spatial and temporal/seasonal patterns of mortality associated with project infrastructure (e.g., different fatality rates near panels on the edge of the arrays vs. the interior area of the arrays).
3. Provide information that will assist the BLM in consultation with the USFWS in understanding which species and potentially which regional populations are at risk.
4. Collect data in such a way that the BLM in consultation with the USFWS may make comparisons with other solar sites.

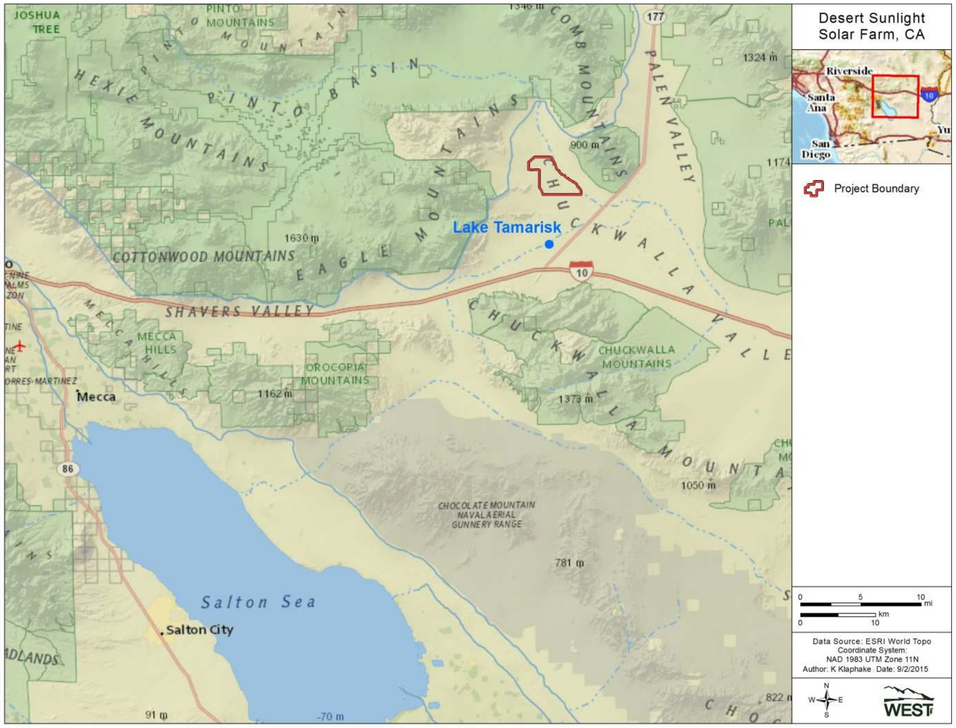

Figure 1. Desert Sunlight Solar Farm Project vicinity map, Riverside County, California.

1.3 Purpose of This Report

This report represents the second seasonal report for the first year of monitoring summarizing monitoring methods and results for avian and bat fatalities and injuries based on the procedures and requirements specified in the approved BBCS. This report covers the period June 01 to August 30, 2015, or the 2015 summer season. For logistical reasons, fall monitoring began on Monday, August 31, 2015. All carcasses and injuries that were discovered by observers are referred to as “detections” in this report. As stated in the approved BBCS, this seasonal report includes the observed detections for likely diurnal, and likely nocturnal species, and for ecological guilds of interest (e.g., raptors, water-associated birds, passerines), for each of the facility types and suspected causes of death. Species composition of detections and the results of the bias trials are also reported. This report presents information related to the spatial distribution of detections, but no formal statistical analysis of the spatial distribution of carcasses will be conducted until the end of the monitoring year, given the limited data presently available.

2.0 METHODS

The BBCS describes the methods by which monitoring and certain analyses, including compilation of the overall fatality estimate, will occur. Below is an abridged description (see BBCS for detailed methods).

2.1 Standardized Carcass Searches

This section describes areas surveyed, the timing and frequency of searches, and the methods by which standardized searches were conducted to identify dead/injured birds and bats at the Project. Dead or injured birds and bats are called detections in this report to provide consistency in naming. This section also describes the methods for conducting carcass removal and searcher efficiency trials; how data were reported and analyzed; and the methods for producing fatality estimates for the Project.

2.1.1 *Areas Surveyed*

Standardized carcass searches were conducted at sampling units, which include the solar arrays (Table 1, 2; Figure 2); the "fenceline" defined as the perimeter fence for the Project (Table 1, Figure 2); and the gen-tie line (from the Project fence to the Red Bluff Substation on the south side of I-10; Table 1, Figure 3). Some overhead lines co-occur with solar arrays (medium voltage overhead lines [MVOH]). The MVOH were part of standardized carcass searches to the extent that they co-occured with solar arrays included in the sample (Table 2; Figure 2).

Table 1. Areas included in standardized carcass searches at the Desert Sunlight Solar Farm Project during summer (June 01 – August 30) 2015.

Project Component	Total Size	Units	% of Component Searched
Solar arrays	1045.9	Hectares	29.5[1]
Fence	16.7	Kilometers	99.0[2]
Gen-tie line	19.2	Kilometers	47.9[3]

[1] Percent area that was searched in summer 2015. Slightly less than 30% total because of unequally-sized arrays.

[2] 74.4% of the fence is fully accessible and surveyed following the standard protocol, while approximately 25% of the fence is surveyed from a distance. Fatality rates estimated for sections of the fence that are sampled were extrapolated to sections of the fence where the standard monitoring protocol cannot be used, as described in section 4.2.6 of the approved Desert Sunlight BBCS. A very short segment near the gate is not sampled due to restoration activities.

[3] 52.1% of the gen-tie will be sampled in 2016.

Comentado [FWS7]: Please describe how detectability is being handled for the 25% being surveyed from a distance.

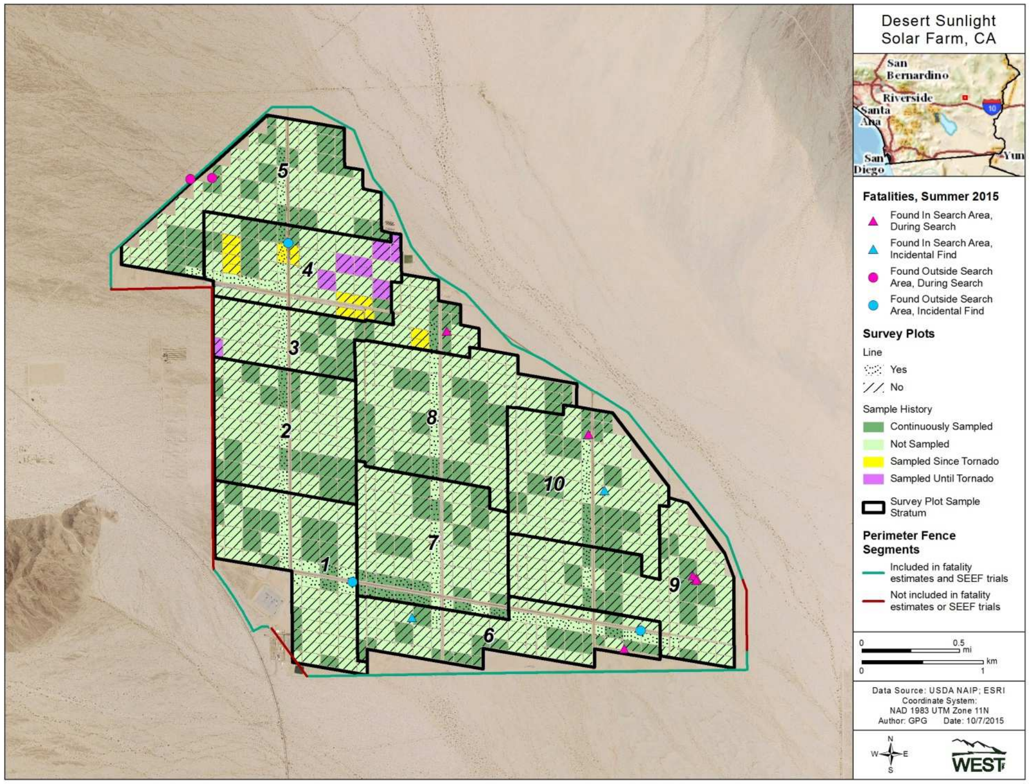

Figure 2. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance) at the solar field, fence, and overhead lines within the fence at Desert Sunlight Solar Farm Project during summer (June 01 – August 30) 2015.

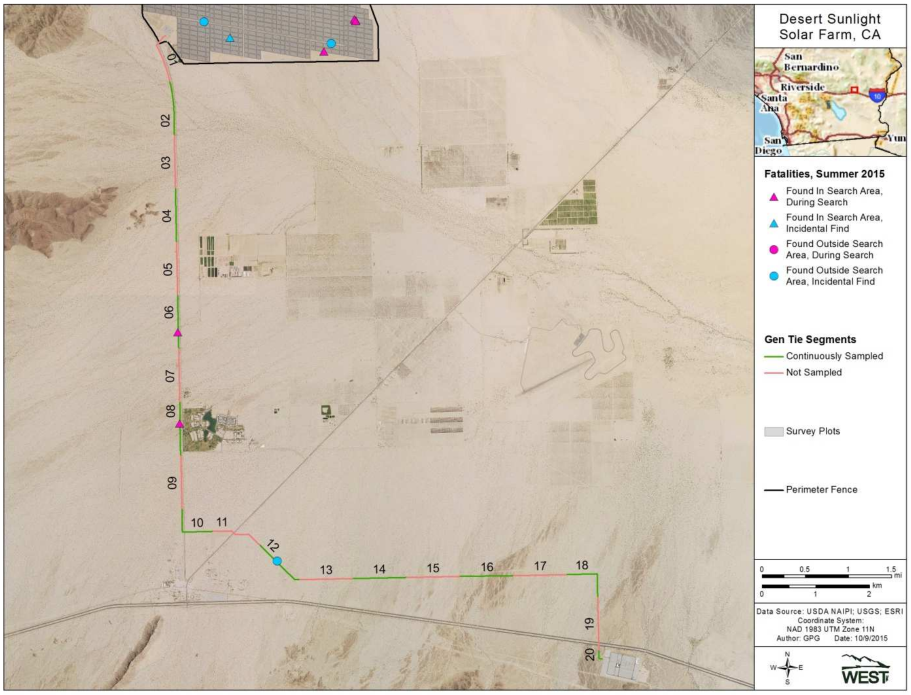

Figure 3. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance activities) along the generation tie line at the Desert Sunlight Solar Farm Project during summer (June 01 – August 30) 2015. Detailed maps of detections along the line are presented in Appendix A.

To ensure a balanced distribution of sample units in the solar field (defined as the collection of all photovoltaic [PV] solar panels), the entire field was divided into ten strata, and individual sampling units were randomly selected within each stratum to compose an approximately 30% sample. This sampling design ensures that units included in the sample were not spatially clumped within the solar field. The solar field consists of arrays of solar panels (referred to as a solar array) that are either 70-m or 140-m wide. The sample includes 133 of each type of array. There are 2,580 70-m rows, and 3,900 140-m rows in the sample.

2.1.1 *Search Frequency and Timing*

Standardized searches occurred during the summer survey season, which includes the period from June 01 through August 30, 2015. All project components included in standardized searches were surveyed four times during summer. All searches took place during daylight hours from 06:30 to 17:00.

Comentado [FWS8]: Please record and report data on the time of the surveys. This will help determine if the surveys can be used to predict nocturnal vs. diurnal mig behavior.

Raw data sheets and GIS files should be submitted with each report.

As specified in the approved Desert Sunlight BBCS, the average search interval for all Project components included in standardized carcass searches during summer was 21.0 days (median 21.0 days). Slight variation in search interval was anticipated due to weather and logistical delays.

Comentado [FWS9]: Please discuss the effect of the long search interval in relation to the carcass persistence trial data.

Table 2. Area and proportion of solar arrays that are and are not associated with overhead lines at the Desert Sunlight Solar Farm Project, Riverside County, CA.

	Line-associated[1]	Not line-associated	Proportion line-associated
Entire facility	89.4 ha	956.5 ha	0.09
Standardized searches	32.2 ha	291.0 ha	0.10

[1] Line-associated area was estimated as the area of any array that fell within the 30-m strip transect below the MVOH.

2.1.2 *Search Methods*

Standardized carcass searches were performed by BLM-approved biologists, in accordance with methods outlined in the BBCS.

Within the solar field, arrays of solar panels were surveyed by observers traveling on foot. A distance sampling approach was used, whereby biologists slowly walked a transect line along the ends of rows of solar panels in a direction perpendicular to the rows, searching ahead and to the side within the array for bird and bat detections. Biologists scanned out to a maximum perpendicular distance of approximately 70 m from the transect. Biologists carried binoculars to allow them to verify the presence of a detection versus rocks or vegetation. Once a detection was confirmed, the distance of the detection to the transect line was estimated using laser range finders. Each array included in the sample was searched by observers walking two transects – one on the west side and one on the east side of the array with observers looking toward the center of the array.

Once a carcass was detected, it was photographed, and data were recorded according to specifications outlined in section 7.2.5 of the approved Desert Sunlight BBCS. Carcasses were then retrieved from their location on the ground, labeled, and placed in a freezer on site.

Comentado [FWS10]: Please explain details about how/when the processing occurred in relation to when carcasses were detected.

Most (74.4%) of the length of fenceline (approximately 10 miles) was searched from a vehicle using the standard protocol (Figure 2). Biologists searched a 6-m wide strip transect centered on the fence from the inner perimeter. Travel speed was below five miles per hour (mph) while searching. Some sections along the fence cannot be driven close to the fence line. The fence line along the western edge of the Project is drivable but the road is approximately 15 m away from the fence and the road and fence are separated by a drainage ditch. The fence along this section is covered with a tan tarp and trees and shrubs have been planted to reduce visibility of the project from the west. Additions of vegetation and the tarp likely reduce potential for bird collision with the fence. This section of the fence was driven to document carcasses, but detections along this portion of the fence are not included in adjusted fatality estimates because detection rates are likely very low. As specified in section 4.2.6 in the approved Desert Sunlight BBCS, we assume that fatality rates are similar between the portion of fence that was searched and the portion that was not. A separate section of the fence in the southeastern corner of the Project cannot be driven because the eastern edge of the berm that bounded construction ponds is too narrow for a vehicle. Along this portion of the fence, the observer stopped at both north and south ends of the berm and used binoculars to search for carcasses. Finally, the road along a portion of the southwest fence line near the entrance gate is approximately 30 to 50 m from the road and is separated from the fence by an area that has recently undergone vegetation restoration. This area was eliminated from sampling. Fatality rates estimated for sections of the fence that were sampled were adjusted to account for the proportion of fence not sampled with the standard monitoring protocol, as specified in section 4.2.6 of the approved Desert Sunlight BBCS.

Comentado [FWS11]: The Service is still concerned that this section of the fence is not being adequately sampled. Mortality rates may be different along this section of the fence.

The gen-tie line was searched using a 30-m wide strip transect (i.e., 15 m of ground on either side of the overhead line). Sample units along the gen-tie line were chosen by dividing the total length of line from the Project fence south to the Red Bluff Substation just south of I-10 into 1-km segments. Thus, a 47.9% sample of the total length of the line was searched (Figure 3). Biologists slowly walked every other 1-km segment of the line, meandering the width of the strip transect, scanning for dead or injured birds or bats within 15 m (49.2 ft) of the overhead line.

For each detection, a suspected cause of death or injury was assigned based on evidence available from the detection, evidence available on Project infrastructure, and proximity of the detection to Project infrastructure. Detections that had evidence of scavenging and lacked evidence on Project infrastructure were assigned as “unknown” because it cannot be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) had a suspected cause of death attributed to the respective Project component. However, it should be noted that there is substantial uncertainty associated with cause of death assignments because no events were directly observed. Detections assigned to the “unknown” category were included in fatality estimates if they were located within standardized carcass search areas, and all detections made during the summer season are reported here.

Comentado [FWS12]: The Servicde disagrees with this assumption. If it’s under the line, the better assumption is that it was caused by the line and a scavenger subsequently discovered the carcass.

2.2 Carcass Persistence Trials

Carcass persistence trials were conducted throughout the summer period. Carcasses from three size classes (small [0-100 g], medium [101-999], and large [1000+ g]) were used for trials. The small size class comprised house sparrows (*Passer domesticus*) and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons (*Columba livia*), chukar (*Alectoris chukar*), and older coturnix quail, and the large size class comprised hen mallard (*Anas platyrhynchos*) and hen ring-necked pheasant (*Phasianus colchicus*).

2.2.1 *Carcass Persistence Data Collection*

To quantify carcass persistence rates, 15 small, 10 medium, and 5 large carcasses were randomly placed and monitored along the gen-tie line during summer 2015. Within the solar arrays and along the perimeter fence, the same numbers of each size category were placed, for a total of 60 carcass persistence trials at Desert Sunlight during the summer season, as specified in the approved Desert Sunlight BBCS. By placing carcasses inside (within arrays and along inner perimeter of the fence) and outside (along the gen-tie) the project fence, the possibility that there are different carcass persistence rates inside and outside the project fence is accounted for. Fifteen carcasses within the Project fence (within solar arrays and along the fence) were monitored using motion-triggered digital trail cameras, while the remaining carcasses were visited on foot, for 30 days or until the carcass had deteriorated to a condition at which it would no longer qualify as a documentable fatality. No carcasses along the gen-tie line were monitored with cameras because of theft and vandalism concerns. Carcasses without trail cameras were visited and photographed once per day for the first four days, and then every three to five days until the end of the monitoring period. To avoid training scavengers to recognize cameras as “feeding stations”, trail cameras were installed five days before specimens were placed, and two fake cameras without bias trial carcasses were also placed within the Project fence and periodically moved to new locations within the fence. Periodic ground-based checking of carcasses with trail cameras also occurred to guard against misleading indicators of carcass removal, such as wind blowing the carcass out of the camera’s field of view. To minimize potential bias caused by scavenger swamping (Smallwood 2007, Smallwood et al. 2010), carcass-persistence specimens were distributed across the entire Project, not just in areas subject to standard searches, and trials were initiated in smaller numbers on three different dates throughout the summer season.

Comentado [FWS13]: This number of carcasses is extremely low. The Service recommends increasing the number of trial carcasses to help reduce the confidence intervals on estimates.

Comentado [FWS14]: With such a low number of carcasses this is unlikely to be a problem.

2.2.2 *Estimating Carcass Persistence Times*

Measurements of carcass persistence rates were subject to censoring. In this context, censoring refers to the instance when a value (e.g. days a carcass is present before being removed) may not be known exactly, but is known to be within a finite range. For example, suppose a carcass was checked on day 7 and was present, and was checked again on day 10, but was found to be missing. The exact time until removal is unknown; however, it is known that the carcass became unavailable at some point between 7 and 10 days. This carcass would be considered “interval censored”. Similarly, if a carcass lasts the entire 30-day trial period, that carcass is “right censored”— it is known that the carcass lasted at least 30 days, but it may have persisted longer. Because carcass persistence data were censored, persistence was analyzed using methods that can accommodate censored data and still produce unbiased estimates of the probability of persistence (Therneau 2015, Therneau and Grambsch 2000).

Comentado [FWS15]: Please describe the interval that carcasses were checked. Is there a reason that they are not checked daily, particularly during the first week?

Comentado [FWS16]: Please clarify how censored data were analyzed and how the analytical methods affected the results. The referenced book is not available to the reader; please provide citation to the agencies. How does the method affect the effective search interval?

Con formato: Punto de tabulación: 8,25 cm, Centrado

USGS-developed fatality estimator software (Huso et al 2012) was used to fit survival models to the censored carcass persistence data. The USGS software used to estimate carcass persistence calculates the period over which there is less than a 1% chance for a carcass to persist. The 'effective search interval' is defined as the shorter of the period during which there is less than a 1% probability that a carcass persists, and the actual search interval (Huso 2010). The probability of persistence is given for the effective search interval, and the probability that a carcass persists through the actual search interval is equal to p (persist through effective search interval) * effective search interval / actual search interval.

There were four distributions implemented in survival models used to estimate the probability a carcass is unscavenged and available to be found at the end of the search interval (*r*): exponential, Weibull, loglogistic, and lognormal. These four distributions exhibit varying degrees of flexibility in order to model a wide variety of distributions of persistence time. Akaike's Information Criterion adjusted for sample size (AICc; Akaike 1973) was used to rank the fit of each survival model with combinations of the covariates carcass size, Project component, season, and visibility, to observed carcass persistence data.

2.3 Searcher Efficiency Trials

Searcher efficiency trials were conducted throughout the summer period. Carcasses from three size classes (small, medium, and large) were used for trials. The small size class comprised house sparrows and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons, chukar, and older coturnix quail, and the large size class comprised hen mallards and hen ring-necked pheasants.

2.3.1 *Searcher Efficiency Data Collection*

Training of biologists on the Project-specific protocol and early assessments of habitat conditions within the solar arrays suggested that the amount of cobble present in the soil may be an important factor influencing searcher efficiency. To satisfy requirements regarding consideration of visibility class per the BBCS and address the influence of cobble cover on searcher efficiency, sample units in the solar arrays and along the gen-tie were stratified by cobble cover and assigned to one of two classes (<15% and >15% cobble cover). Classes were determined by making ocular estimates of cobble cover at each sample unit and then evaluating the frequency histogram of sample units across the range of estimated cobble cover (Figure 4). A natural break point was identified at 15% cobble cover, so the same value was chosen as the break point that defined the two cobble cover classes. Thus, in the solar arrays, two sets of searcher efficiency trials were conducted (one set in each cobble cover class; *n* for each trial = 15 small birds, 10 medium birds, and 5 large birds as agreed upon in section 7.4 of the approved Desert Sunlight BBCS). Along the gen-tie, visibility was expected to be related to vegetation and rock cover. Thus, searcher efficiency trials along the gen-tie occurred in two visibility classes (*n* for each class = 15 small birds, 10 medium birds, and 5 large birds (easy: ≥90% bare ground, vegetation <6" tall; and more difficult: <90% bare ground, vegetation ≥6" tall). Inadvertently, one large carcass was not placed and one extra small carcass was placed during summer, so total sample size for large carcasses along the gen-tie was nine, and for small carcasses was 31. Thirty searcher efficiency trials (*n* = 15 small birds, 10 medium birds, and 5 large birds) occurred along the fence in the only visibility class present on the fence (easy visibility). Thus, during summer, a total of 150 searcher efficiency trials occurred at the Project. Locations for trials were chosen by taking a randomized sample of all locations included in standardized carcass searches.

Comentado [FWS17]: The Service proposed larger sample sizes for carcass persistence and searcher efficiency trials. Hence, has this been evaluated as adequate to determine searcher efficiency for a single strata? Please provide justification for small sample size.

Comentado [FWS18]: The terminology here is inconsistent with above. Each carcass counts as a trial or a trial consist of n carcasses?

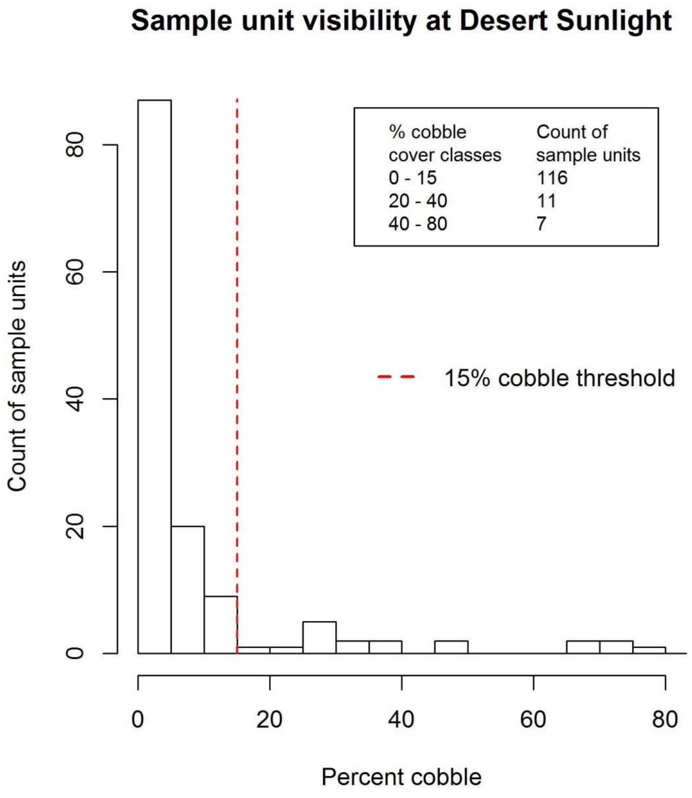

Figure 4. Frequency histogram of sample units (in the arrays only) at Desert Sunlight Solar Farm Project by estimates of cobble cover. Based on this distribution, each sample unit was assigned to one of two classes of cobble cover (<15%; >15%).

2.3.2 *Estimating Searcher Efficiency*

Comentado [FWS19]: Is searcher efficiency tested for each observer? Please provide these results along with an indication of variation in searcher efficiency across observers.

Searcher efficiency at Desert Sunlight was estimated separately for linear features (the project fence and the generation tie line), and the solar arrays, reflecting the different search methods used on arrays and linear features. For linear features, logistic regression models were fit to searcher efficiency data and AICc was used to compare models. Models including effects of carcass size (three classes), visibility (two classes; gen-tie only), and season were compared to each other and the null model. Model selection indicated that the best model included main effects of Project component, carcass size, and season. Once the best model was chosen and appropriate classes identified, searcher efficiency, or the proportion of carcasses detected, p, was calculated for each class using the following equation:

$$p = \frac{Number\ of\ Carcasses\ Observed}{Number\ of\ Carcasses\ Available}$$

The data for this analysis included all searcher efficiency trial carcasses from the summer 2015 season.

For the solar arrays, searcher efficiency was evaluated using a distance sampling approach (Buckland et al. 1993). Distance sampling assumes perfect detection on the transect line (at distance = 0), an assumption that is likely valid in the solar arrays given the relatively flat & vegetation-free nature of the soil surface. A curve is fitted to the observed carcass data that predicts probability of detection as a function of distance from the transect line. The mean value of this function over a specified distance, *w,* is equal to the average searcher efficiency for a transect of width *w*. The mean value of the detection curve is the integral of the detection function calculated between 0-m and the maximum survey distance (*w;* half the width of the solar array row), divided by the maximum survey distance:

$$p = \frac{\int_0^w f(x)dx}{w},$$

Con formato: Resaltar

where f(x) is the detection function evaluated at distance, *x*.

One departure in the methods used here, relative to the methods presented in Buckland et al. (1993), was that for this study the detection function was estimated using trial carcasses, which meant that there were both presence (detected) and absence (not detected) data available to fit the detection function (Figure 5). The availability of both presence and absence data means that the detection function can be estimated using only trial carcasses whose distribution is known. Therefore the detection function, the average searcher efficiency among the arrays and the final fatality estimate within the arrays are all insensitive to the spatial distribution of carcasses within individual arrays, and the overall searcher efficiency estimate is valid even if the distribution of carcasses among the arrays is not uniform.

Distances of trial carcasses (trials both found and missed) from the transect line were used to fit a half-normal detection function for searches among the arrays (Figure 5). The half-normal detection function is a commonly used function for distance sampling surveys (Buckland et al. 1993). The detection function was fit with and without covariates (carcass size, visibility index, or no covariates) and AICc indicated that the best among these models included only carcass size as a covariate.

Comentado [FWS20]: Please provide an analysis that the sample size is adequate to detect a difference between visibility categories. This result seems to be an artifact of the low sample size.

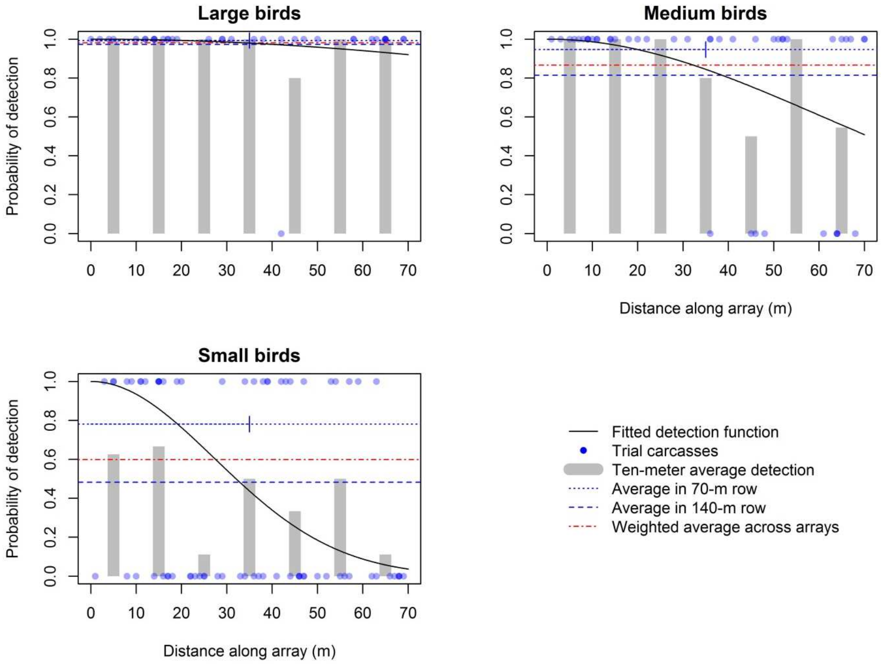

Figure 5. **Estimated detection probabilities for bird carcasses by size class during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California. Distance sampling was used when searching solar arrays only. Average probability of detection over 70-m (arrays relying on a 35-m viewshed) and 140-m (arrays relying on a 70-m viewshed) panel rows in solar arrays are presented.**

Comentado [FWS21]: Please explain the dots in the figure. The number of dots is greater than the number of trial carcasses.

Because the solar arrays were surveyed by searchers who walked down both sides of the rows of panels, the width of the search transect was specified as half the width of the rows of panels. For larger birds, there is almost certainly a non-zero detection probability beyond this distance but the bias that occurs by ignoring this non-zero detection probability is conservative (i.e. the searcher efficiency is underestimated). Some solar arrays have row widths of 70 m (search transect width of 35 m) and some have row widths of 140 m (search transect width of 70 m). The weighted average searcher efficiency is calculated based on the number of panel rows of each length in the survey sample:

$$p_{weighted\ average} = \frac{n_{70}}{n} \times \int_0^{35} f(x)dx + \frac{n_{140}}{n} \times \int_0^{70} f(x)dx,$$

Comentado [FWS22]: The denominator (w) from the equation for p (from page 12 equation) is missing from this equation. Is this a typo or was the equation modified for a reason? If so, please explain.

where n_{70} is the number of 70-m rows in the sample, n_{140} is the number of 140-m rows in the sample, and *n* is the total number of rows in the sample. Searcher efficiency was higher for the arrays with a width of 70 m, and overall searcher efficiency was estimated as a weighted average based on the proportions of 70-m arrays and 140-m arrays in the sample units.

Comentado [FWS23]: Please provide the values for n_{70} and n_{140}.

2.4 Fatality Estimator

Fatality rate estimation is a complex task due to several variables inherent to every fatality monitoring study. Carcasses may persist for variable amounts of time due to local scavenger activity or environmental conditions leading to carcass degradation over time. Carcasses and feather spots are also detected with varying levels of success based on carcass characteristics and ground cover (e.g., vegetated areas underneath the gen-tie line versus cleared areas beneath solar panels). For these reasons, it is generally inappropriate to draw conclusions based on the raw number of fatalities alone. The desire to estimate fatalities given these variables has driven the development of several statistical methods for estimating fatalities (e.g., Smallwood 2007, Huso 2010, Korner-Nievergelt 2011). All of these fatality estimation methods share a similar underlying model. Generally, the fatality estimation for a given site may be written as:

$$F=C/rp,$$

where F is the total number of fatalities, C is the number fatalities detected and included in fatality estimation, r is the probability a carcass is unscavenged and available to be found at the end of the search interval, and p is the probability of detecting a carcass (Huso 2010).

Comentado [FWS24]: Is this the weighted average probability from above?

All fatality estimates were calculated using the Huso estimator, as well as 90% confidence using bootstrapping (Manly 1997). Bootstrapping is a computer simulation technique that is useful for calculating point estimates, variances, and confidence intervals for complicated test statistics. A total of 1,000 bootstrap replicates were used. The lower 5th and upper 95th percentiles of the 1,000 bootstrap estimates provide estimates of the lower limit and upper limit of an approximate 90% confidence interval on all estimates.

Comentado [FWS25]: Please describe what was bootstrapped and how. The table in the appendix is difficult to understand without a better understanding of the bootstrapping methods.

2.5 Incidental Reporting

Some detections were outside standardized search areas, or were within search areas but not observed during standardized searches. Such detections were found by WEST avian biologists and operational personnel and were considered “incidental” detections. When found by operational personnel, these detections were reported to WEST avian biologists for documentation. Data on incidental detections are reported here, as well as in the Desert Sunlight SPUT Avian Injury and Mortality Report Forms June – August 2015. All detections made in search areas during the reporting period were included in fatality estimates, regardless of whether they were detected incidentally or during searches.

3.0 MONITORING RESULTS

3.1 Summary of Avian Detections

During summer 2015, a total of 15 avian detections (including incidentals) of 11 identified species were recorded (Table 3). The most common identified species was common raven (*Corvus corax*) with three detections. Most detections (n = 11, or 73.3% of total detections) occurred in the solar arrays (Figures 2 and 3; Tables 4, 5, and 6). Ten (66.7%) detections were made during standardized carcass searches and five (33.3%) were documented as incidentals. No bats were detected during the summer season. For fresh carcasses, body weights and weather conditions the preceding nights are described in Appendix B.

Table 3. Number of individual bird detections, by species, during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California. LA = line-associated; NLA = non-line associated.

Common Name	Scientific Name	Migration Behavior*	Guild	LA Solar Array	NLA Solar Array	Fence	Gen-tie Line	Total
common raven	*Corvus corax*	resident	Corvids	-	2	1	-	3
white-winged dove	*Zenaida asiatica*	variable	Doves/Pigeons	-	-	-	1	1
black-throated sparrow	*Amphispiza bilineata*	diurnal	Grassland/ Sparrows	-	-	-	1	1
sora	*Porzana carolina*	nocturnal	Rails/Coots	-	-	-	1	1
Virginia rail	*Rallus limicola*	nocturnal	Rails/Coots	1	-	-	-	1
house wren	*Troglodytes aedon*	nocturnal	Wrens	1	-	-	-	1
mourning dove	*Zenaida macroura*	variable	Doves/Pigeons	-	1	-	-	1
Say's phoebe	*Sayornis saya*	diurnal	Flycatchers	-	1	-	-	1
northern rough-winged swallow	*Stelgidopteryx serripennis*	diurnal	Swallows	-	1	-	-	1
unidentified bird (small)	-	-	Unidentified Birds	-	1	-	-	1
unidentified bird (unknown size)	-	-	Unidentified Birds	-	1	-	-	1
unidentified grebe	-	-	Waterbirds/ Waterfowl	-	1	-	-	1
western grebe	*Aechmophorus occidentalis*	nocturnal	Waterbirds/ Waterfowl	-	1	-	-	1
Total				**2**	**9**	**1**	**3**	**15**

* See literature cited for migration behavior references; information for most species was taken from the respective species accounts found in Birds of North America (BNA) Online (http://bna.birds.cornell.edu/bna/); where information on migration behavior was lacking in BNA accounts, Newton (2008) or Murray (2004) were used.

Comentado [FWS26]: Aechmophorus species or a different genus?

Table 4. Total avian detections by Project component and detection category during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California. Only carcasses found within search areas were included in fatality estimates.

	Inside carcass search area		Outside carcass search area	
Project Component	**Carcass search**	**Incidental**	**Carcass search**	**Incidental**
Fence	0	0	1	0
O&M Building	0	0	0	0
Gen-tie line	2	0	0	1
Solar arrays				
Line-associated	0	0	0	2
Non-line associated	7	1	0	1

Table 5. Total avian detections (including incidentals) by Project component and suspected cause of death during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California.

	Suspected Cause of Death*				
Project Component	**Collision**	**Predation**	**Other**	**Unknown**	**Percent of Total**
Fence	0	0	1	0	6.7
O&M building	0	0	0	0	0
Gen-tie line	2	0	1	0	20
Solar arrays					
Line-associated	1	0	1	0	13.3
Non-line associated	1	0	5	3	60
Percent of Total	**26.7**	**0**	**53.3**	**20.0**	**100.0**

* Suspected cause of death was assigned based on evidence available on the detection, evidence available on Project infrastructure, and proximity of detection to Project infrastructure. Detections that had evidence of scavenging and lacked evidence on Project infrastructure were assigned as "unknown" because it can't be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) had a suspected cause of death attributed to the respective Project component. However, in the absence of a completed necropsy, there is ~~substantial~~ some uncertainy associated with cause of death assignments because no events were directly observed.

Comentado [FWS27]: Was proximity to project features evaluated? Please describe how this information was utilized. Proximity distances may provide insights into which features may pose the greatest risks.

Comentado [FWS28]: Since scavenger rates are so high, this definition too easily categorizes carcasses as unknown. Low levels of scavenging should not exclude birds from a more thoughtful evaluation of the cause of the mortality. Other criteria should be considered, including patterns of disturbed dust on solar panels, proximity to a feature with collision risk. Such a blanket categorization, probably masks useful information.

3.2 Temporal Patterns of Avian Detections

The number of detections recorded daily during the reporting period ranged from zero to three (Figure 6). One detection was found per day with the exception of June 24 when three detections occurred. The number of detections per day represents those discovered during standardized carcass searches and incidentally.

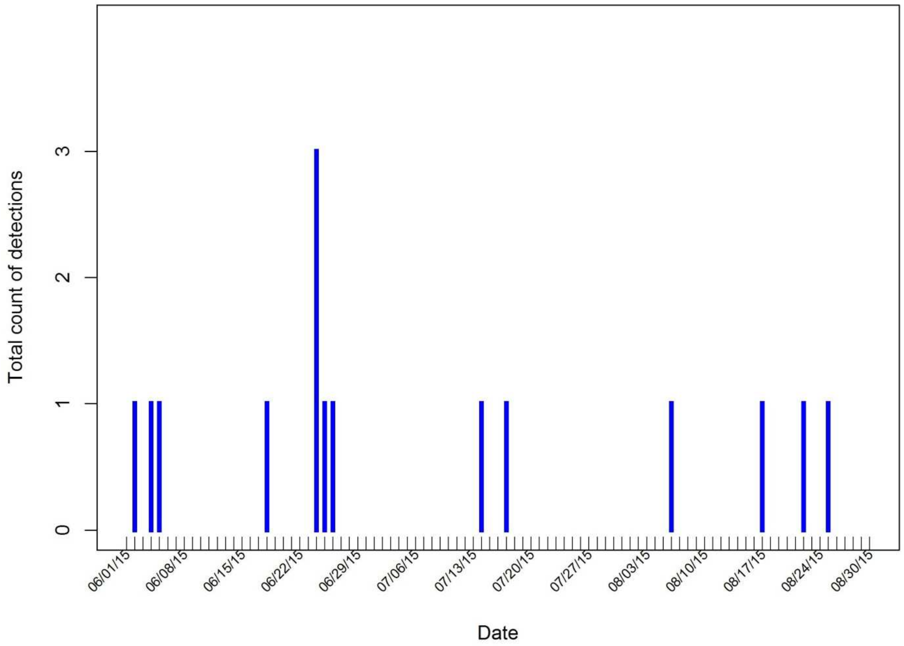

Figure 6. Total number of detections by date during summer (June 01 – August 30) 2015 at the Desert Sunlight Solar Farm Project, Riverside County, California.

3.3 Spatial Distribution of Avian Detections

Comentado [FWS29]: Spatial distribution of different taxonomic groups should be discussed, particularly as more data come in.

3.3.1 *Detections by Project Component*

During the reporting period, detections were documented from the solar arrays, the northern section of the perimeter fence, and the gen-tie line; no detections occurred at the O&M building (Tables 3, 4, and 5). Of the 11 detections within the solar arrays, 18.2% (2) were associated either with overhead lines or arrays that co-occurred with overhead lines.

3.3.2 *Feather Spot Detections*

Five (33.3%) of the 15 detections consisted only of feather spots. Along the gen-tie, one of three detections (33.3%) was a feather spot. No detections along the fence were a feather spot. Four of 11 detections (36.4%) in the solar arrays were feather spots.

3.4 Detections of Injured Birds

No injured birds were detected during the summer 2015 season.

3.5 Summary of Bat Detections

No bats were detected during the summer 2015 season.

3.6 Carcass Persistence Trials

Data from carcass persistence trials were available from late winter, spring, and summer at the solar field and gen-tie line (n = 154 total). Based on carcass persistence data from late winter, spring, and summer 2015, survival models were compared for relative quality using the corrected AICc score, as suggested in Huso (2010). The AICc score provides a relative measure of model fit and parsimony among a selection of candidate models, and provides a framework for testing hypotheses regarding which factors contribute to carcass persistence rates. Carcass size was tested as a potentially important variable, as larger carcasses tend to persist longer and may be more likely to leave feather spots which persist for long durations, whereas smaller carcasses may be more likely to be completely removed. Project component (solar arrays/fence, generation-tie line) was also included as a potentially important variable, as was season.

Comentado [FWS30]: This is not clear. Are you suggesting that feather spots from large carcasses last longer than feather spots from small carcasses? Or are you suggesting that large carcasses are more likely to produce feather spots than small carcasses and feather spots in general (large or small) persist for long durations? Please clarify and provide a rationale for the assertion and describe how it might affect the analysis.

The model with lowest AICc score is typically chosen as the "best" model relative to other models tested; however, any model within two AICc points of the best model is considered competitive with the best model (Burnham and Anderson 2004). The best model included main effects of season, carcass size, Project component, and interactions of Project component × season and Project component × size with a Weibull-distributed removal time. Given the main effect of season, further modeling efforts were restricted to data collected in summer only. The best model using only the summer data suggested an interaction between carcass size and Project component. Estimates of carcass removal time and persistence probabilities are reported in Table 6 from the best model, and estimates of proportion of carcasses remaining as a function of days since carcass placement are provided in Figure 7.

Comentado [FWS31]: Is there enough data to do a good analysis?

Table 6. Mean carcass removal time and probability of a carcass persisting through the effective search interval during the summer season (June 01 – August 30) at the Desert Sunlight Solar Farm Project, Riverside County, California.

Carcass size	Project component	Mean removal time (days)	Probability of persistence
Small	Arrays/fence	15.53	0.63
Small	~~Overhead~~ Gen-Tie lines	1.37	0.22
Medium	Arrays/fence	19.2	0.73
Medium	~~Overhead~~ Gen-Tie lines	14.75	0.60
Large	Arrays/fence	-*	1.00
Large	~~Overhead~~ Gen-Tie lines	0.9	0.22

* Mean removal time was not estimated because no removal was observed for large carcasses within the solar field.

Comentado [FWS32]: Please include the timeframe for the persistence trails for ease of reference (30 days?).

Comentado [FWS33]: This looks like there may be an effect on persistence time from being outside the fence. This may be due to differences in the scavenger community. Was this tested?

Comentado [FWS34]: This is the Gen-Tie, right? Better to refer to this as the Gen-Tie to distinguish it from the internal overhaed lines above the panels.

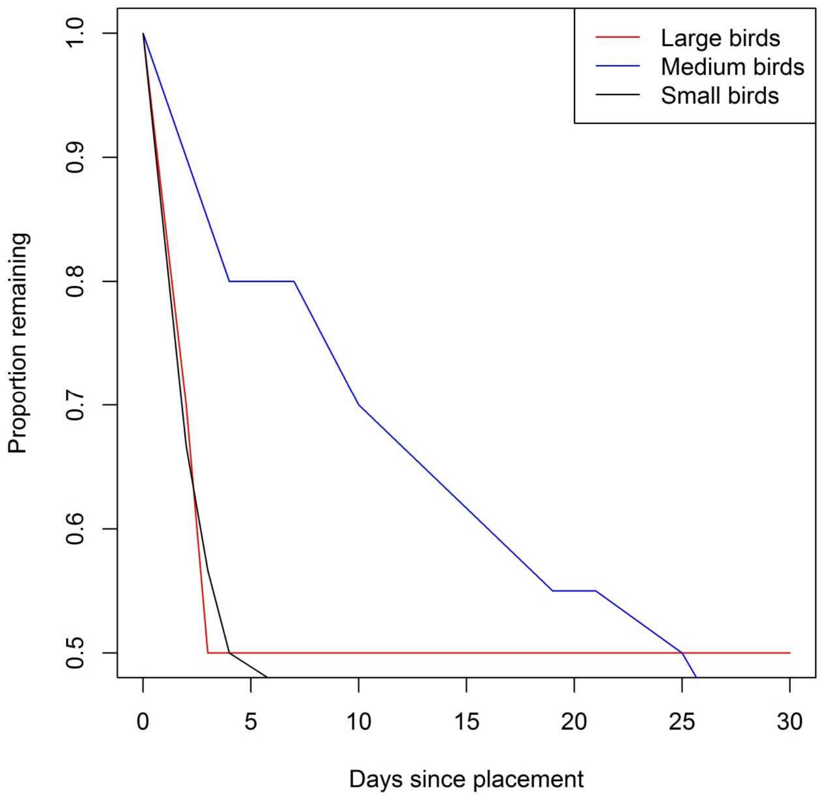

Figure 7. Proportion of trial carcasses remaining as a function of days since placement and carcass size class (n = 30, 20, and 10 for small, medium, and large size classes, respectively) during the summer (June 01 – August 30) 2015 season at the Desert Sunlight Solar Farm Project, Riverside County, California.

Comentado [FWS35]: The y-axis is cut off at 0.5. This obscures data for small and med bird size categories. Please provide the Figure with a y-axis range from 0.0-1.0.

3.7 Searcher Efficiency Trials

During the reporting period, a total of 150 searcher efficiency trials were placed at the Project. Most trials were available to be found, but some disappeared before or during the trial. Overall, 60 trials were placed in the solar arrays and 44 were available to be found; 30 trials were placed along the perimeter fence (inner perimeter only) and 30 were available to be found; and 60 trials were placed along the gen-tie line and 55 were available to be found.

Comentado [FWS36]: How was this broken down by visibility categories and size classes? See Appendix C?

In the solar arrays, the model that included an effect of carcass size was chosen as the best model to estimate searcher efficiency. Within the solar arrays, searcher efficiency was: 60.0% for small birds, 86.6% for medium birds, and 98.1% for large birds (Figure 5).

For linear Project components, the model that included an effect of carcass size, Project component, and season was chosen as the best model to estimate searcher efficiency. Along the fence, searcher efficiency ranged from 87.5% to 100% depending on carcass size class. Along overhead lines, searcher efficiency ranged from 43.5% to 100%. Detailed estimates of searcher efficiency estimates specific to each component and carcass size are reported in Appendix C.

3.8 Fatality Estimates

Fatality estimates were calculated separately for each component (solar arrays, fence, and overhead lines). Ultimately, five detections were excluded from the fatality analysis because they were found outside standardized search areas. All 15 detections made during summer are reported in Table 3.

Comentado [FWS37]: Please provide an additional summary tables with the following information for each component and for the entire facility: carcasses detected, estimated fatalities; 90% CI. An additional table with the same information for each size category is also requested.

During summer 2015, there were an estimated total 148 carcasses (90% CI: 10 – 365) at the Project. Of these, 44 carcasses (27.5%; 90% CI: 8 – 64) were estimated for the solar arrays and 104 carcasses (66.9%; 90% CI: 2 – 339) were estimated for the gen-tie line. While we are required to report the gen-tie estimates per the approved BBCS, these estimates are not reliable due to the high rates of scavenging that were observed during the limited trials at the gen-tie and the low number of carcasses detected (n = 2 in the fatality analysis). No carcasses were estimated for the perimeter fenceline because there were no detections made along the fence. All of these estimates should be interpreted with caution because variance estimates are in general unreliable when carcass counts are low (< 5 per category). ~~Other projects (e.g. Ivanpah) are not reporting estimates when carcass counts are less than or equal to five. However, t~~The TAG has asked for both the estimates and confidence intervals for this project with the appropriate caveat added. There were an estimated ~~0.0~~17 fatalities per 1000 acres (within the solar field only; 44 estimated carcasses/2,585 acres) and an estimated 0.08 fatalities per nameplate MW (44 estimated carcasses/550 MW) within the solar field. A complete list of estimates for each Project component and carcass size class with confidence intervals is presented in Appendix C.

Comentado [FWS38]: The Service continues to recommend 95% CI, but even at 90% the CI is still too wide to be useful.

Comentado [FWS39]: Given the size of utility scale projects “per 1000 acres seems more appropriate.

4.0 DISCUSSION

The 2015 summer season represented the second full season of standardized monitoring at Desert Sunlight per the BBCS. Searcher efficiency trials and carcass removal trials were conducted concurrently at the solar arrays, fencelines, and along the gen-tie line. Data from these trials were used to produce fatality estimates adjusted for searcher efficiency and carcass persistence bias. Although these estimates were produced from a statistically robust sample, only limited inference may be drawn from two seasons of data. These results should be considered preliminary because estimating carcass persistence, searcher efficiency, and adjusted numbers of fatalities within each season represents information based on a limited sample size. As more data are collected throughout the monitoring year (and additional quality assurance/quality control measures occur, for example characterizing feather spots to species or size class), data from all seasons may be pooled. At that time, data will be tested for seasonal differences retrospectively, but because seasonal estimates will be produced from the much larger annual data set, they may differ from what is reported here because they are based on a larger, more informative sample.

4.1 Carcass Persistence and Searcher Efficiency Trials

The degree to which carcasses persist on the landscape depends on a variety of factors reflecting seasonal and inter-annual variation in habitat, climate, and the scavenger community. The composition and activity patterns of the scavenger community often vary seasonally as birds migrate, new juvenile birds and mammals join the local population, and mammalian scavengers variably hibernate or estivate. The scavenger community may also vary substantially from year to year because of variation in annual reproduction and survival related to changes in landscape condition. Climatic conditions that vary seasonally and annually also may contribute to variation in carcass decay and removal rates due to variation in temperatures, solar insolation, wind patterns, and the frequency of flooding events. Thus, rates of carcass persistence reported here should be interpreted cautiously as they may change over the coming months.

Searcher efficiency was influenced by Project component, carcass size, and season. In the solar arrays, searcher efficiency was high (> 0.5) for all carcass size classes and this is likely influenced by the limited vegetation cover beneath solar panels. Beneath the gen-tie line, vegetation cover is higher in some portions of the strip transects, but results reported here support the hypothesis that visibility class is not a factor in searcher efficiency along the lines during summer.

Comentado [FWS40]: Given the low number of trial carcasses, you can detect a difference between visibility classes.

For the current analysis, searcher efficiency in the solar arrays was assumed to be best predicted by a half-normal distribution. For future analyses, AICc will be used to compare and choose the best among multiple detection functions.

4.2 Distribution of Fatalities and Fatality Estimates

The number of detections was more or less evenly distributed across the summer season, and there were no clear associations between number of detections and date. Given the small number of detections overall, it is premature to draw any conclusions about the spatial distribution of carcasses.

Composition of detections during summer 2015 included eight avian guilds. Corvids comprised the majority of detections (n = 3): there were two detections each within the doves/pigeons, rails/coots, and waterbirds/waterfowl guilds. No bats have been detected since monitoring began at the Project.

Detections attributed to an unknown cause accounted for 20.0% of all detections during the reporting period, and all those attributed to an unknown cause were found in the solar arrays. Of the 11 detections made in the solar arrays, 36.4% were feather spots. Determining a cause of mortality from a feather spot is challenging because there is rarely visible evidence available on which to determine a cause of death. Thus, feather spots with an unknown cause of mortality could be encountered anywhere birds occur, and an unknown cause of a sizeable proportion of the carcasses is not unique to the Project. Further, the relatively large proportion of feather spots (33.3%) among the detections for the Project as a whole may inflate the fatality estimate when unknown cause detections are included based on the potential for multiple feather spots resulting from one fatality, feather spots resulting from predation not associated with the facility, or other causes. However, feather spots are included in the analysis here to provide a more conservative estimate of fatality.

Comentado [FWS41]: What fraction of these unknown detections are feather spots?

Comentado [FWS42]: We don't agree with this statement. This is unknown. Feather spots may be more mobile, but as far as I know there have been no studies on whether they "multiply" and cause bias. If there has, please provide a reference. It is possible that feather spots could accumulate along fences, but in general, they are just as likely to migrate into a survey area as they are to leave. If this is a significant problem, then I recommend shorter search intervals and more complete coverage of the project site.

EXECUTIVE SUMMARY

Avian and bat monitoring surveys were conducted from June 01 to August 30, 2015 (the summer season; for logistical reasons, fall monitoring started on Monday, August 31, 2015) at Genesis Solar Energy Project (Project) in accordance with the Project's Bird and Bat Conservation Strategy (BBCS). Specifically, standardized carcass searches, searcher efficiency trials, and carcass persistence trials were conducted. This report represents the second seasonal report for the first year of monitoring, and summarizes monitoring methods and results for those surveys based on the procedures and requirements specified in the BBCS.

Standardized carcass searches were conducted 1) in the solar field, consisting of a random stratified 30% sample of solar troughs of both Project units, 2) at each evaporation pond, 3) along the perimeter of each power block and beneath each air condensed cooling (ACC) unit, 4) along inner and outer portions of the "fenceline", resulting in 100% of the length of the perimeter fence surveyed, and 5) along 25% of the total length of generation-tie (gen-tie) and distribution lines (collectively, overhead lines) from the southernmost Project fence to Wiley's Well reststop, which co-occur with the Project access road. Searches were conducted within the summer season at intervals of approximately 21 days, and all components were searched four times.

All bird and bat fatalities and injuries that were discovered by observers, referred to as "detections" in this report, including those found incidentally and during standardized carcass searches, were documented. During the reporting period, 55 avian detections and five bat detections were made.

According to specifications of the BBCS, avian detections were categorized by likely diurnal or nocturnal migration behavior, ecological guild (e.g., raptors, songbirds, etc.), facility component, and suspected cause of death. These standardized carcass search results, along with searcher efficiency and carcass persistence rates from bias trials conducted on site, were input into a fatality estimator model (Huso 2010) to provide a preliminary estimate of the number of fatalities that occurred at the Project during the reporting period adjusted for sources of bias. The estimate is considered preliminary because the annual report may pool information from bias trials and other data across seasons which could affect seasonal estimates.

Carcass persistence was influenced by Project component, carcass size, and, in the solar field (solar collector troughs + perimeter fence), season. In the solar field, small carcasses (0-100 g) had a 52% (90% confidence interval [CI]: 45 – 64%) chance of persisting through the 21-day search interval, medium carcasses (101 – 999 g) had an 92% (90% CI: 76 – 96%) chance, and large carcasses (1000+ g) had a 100% chance. Mean removal time for small, medium, and large carcasses in the solar field was 8.0 and 35.1 days for small and medium carcasses, respectively. Mean removal time for large carcasses in the solar field was not estimated because no removal of large carcasses was observed. Along overhead lines, small carcasses had a 14% (90% CI: 9 – 20%) chance of persisting through the 21-day search interval, medium carcasses had a 59% (90% CI: 42 – 74%) chance, and large carcasses had a 41% (90% CI: 26

Comentado [FWS1]: 30% of the entire project, not 30% of each unit, correct?

Comentado [FWS2]: FWS still asserts that 25% of the utility lines is too little given that transmission appears to be having significant effects on birds.

Comentado [FWS3]: Time of survey matters as to whether or not one can draw any conclusions about this. Please provide a summary of when surveys were conducted.

Comentado [FWS4]: IMPORTANT: WEST has said that it modified the Huso estimator, and despite several requests, those modifications have not been shared with the agencies. Until we understand what changes to the code were made, we are reserving judgment on these results.

Comentado [FWS5]: Please explain how carcass persistence is influenced by project component.

Comentado [FWS6]: Is the fence being tested? The carcass persistence section only mentions trials in the SCA and the Gen-Tie.

Comentado [FWS7]: Please report median removal times and a figure showing the curve of # remaining over time.

– 58%) chance. Mean removal time along overhead lines for small, medium, and large carcasses was 0.8, 12.8, and 4.6 days, respectively.

Comentado [FWS8]: This supports increased frequency for this component.

In the solar field, searcher efficiency was 92% (86 – 98%) and there was no effect of carcass size, visibility class, or season. Along overhead lines, searcher efficiency was influenced by carcass size: 54% (90% CI: 39 – 68%) for small birds, 100% for medium birds, and 100% for large birds.

Comentado [FWS9]: Is this the searcher efficiency averaged for all observers? What is n?

Composition of summer detections included species from 13 avian guilds. No single guild comprised a large number of detections: the most common was blackbirds/orioles (eight detections). Shorebirds and waterbirds/waterfowl were represented by six and seven detections, respectively. Summer was the first season in which bats were detected.

Using the Huso (2010) fatality estimator model, during the summer period 2015, there were an estimated total 100 carcasses (90% CI: 81 - 145) at the Project. Of these, 53 carcasses (53%) were estimated for the SCAs, 8 carcasses (8%) were estimated for the fence, 9 carcasses (9%) were estimated for evaporation ponds, 23 carcasses (23%) were estimated for power blocks, and 7 carcasses (7%; 90% CI: 6 - 21) were estimated for the overhead lines and project road. An estimated 93 (93% CI: 66 - 126) carcasses (0.05/acre, 0.37/nameplate MW) occurred for all components associated with both solar units (SCAs, power block, evaporation ponds, and along the perimeter fence, combined).

1.0 INTRODUCTION

1.1 Project Background

The Genesis Solar Energy Project (referred to in this report as "Project") consists of two solar power electrical generating facilities (Units 1 and 2) with a combined net capacity of 250 megawatts. The Project facility consists collectively of two power blocks, power generating equipment (solar collector assemblies [SCAs] of mirrored parabolic troughs [solar troughs or troughs]), support facilities, and evaporation ponds. Linear facilities include a transmission line, distribution line, natural gas pipeline, and a main access road that are mostly co-located for approximately 10.5 km (6.5 miles). The Project comprises approximately 1,800 acres (728 hectares [ha]). The solar field and associated structures comprise 1,727 acres (699 ha) and linear facilities comprise 93 acres (38 ha). The Project is located on land managed by the Bureau of Land Management (BLM) 25 miles (40 kilometers [km]) west of Blythe, in Riverside County, California (Figure 1).

1.2 Monitoring Plan Overview and Goals

A Bird and Bat Conservation Strategy (2015; “BBCS”) was prepared by the Project proponent in collaboration with the U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), California Energy Commission (CEC), and Bureau of Land Management (BLM) to guide comprehensive monitoring of impacts to birds and bats associated with operation of the Project. Final agency acceptance of the BBCS occurred in March 2015.

The BBCS details post-construction monitoring to be conducted and the data analysis and reporting processes that will be implemented by Genesis Solar in collaboration with the USFWS, CDFW, CEC, and BLM. As identified in the BBCS, they are:

1. Estimate overall annual avian fatality rate and species composition associated with the Project infrastructure. This estimate will include mortality associated with SCAs, overhead lines including the generation (gen-tie) line, perimeter fence and other features of the Project that may result in injury and fatality.
2. Determine whether there are spatial and temporal/seasonal patterns of mortality associated with project infrastructure (e.g., different fatality rates near SCAs on the edge of the solar field versus the interior area of the solar field).
3. Provide information that will assist the CEC and BLM, in consultation with the USFWS and the CDFW, in understanding which species and potentially which regional populations are at risk.
4. Collect data in such a way that the CEC and BLM, in consultation with the USFWS and CDFW, may make comparisons with other solar sites.

1.3 Purpose of This Report

This report represents the second seasonal report for the first year of monitoring summarizing monitoring methods and results for avian and bat fatalities and injuries based on the procedures and requirements specified in the approved BBCS and as required by CEC Condition of Certification BIO-16. This report covers the 2015 summer season, which includes the period from June 01 to August 30, 2015. For logistical reasons, fall monitoring started on Monday, August 31, 2015. As stated in the approved BBCS, this seasonal report includes the observed fatality rates broken out by likely diurnal, and likely nocturnal species, and for ecological guilds of interest (e.g., raptors, water-associated birds, passerines), for each of the facility types and suspected causes of death. Species composition of carcasses and the results of the bias trials are also reported. This report presents information related to the spatial distribution of carcasses, but no formal statistical analysis will be conducted until the end of the monitoring year, given the limited data presently available.

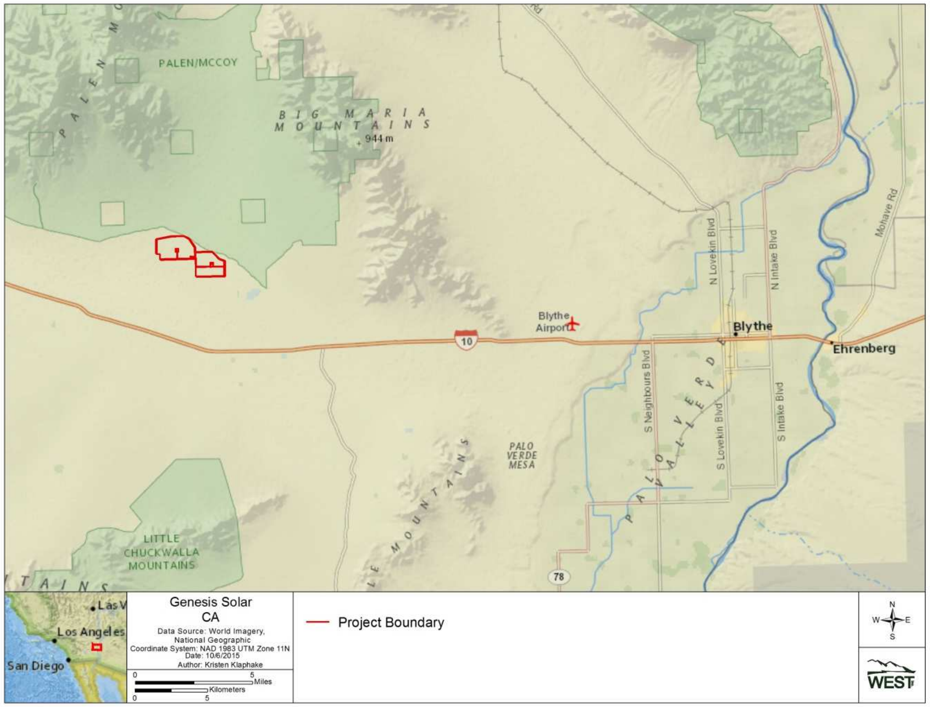

Figure 1. Genesis Solar Energy Project vicinity map, Riverside County, California.

2.0 METHODS

The BBCS describes the methods by which monitoring and certain analyses, including compilation of the overall fatality estimate, will occur. Below is an abridged description (see BBCS for detailed methods).

2.1 Standardized Carcass Searches

This section describes areas surveyed, the timing and frequency of searches, and the methods by which standardized searches were conducted to identify dead/injured birds and bats at the Project. This section also describes the methods for conducting carcass removal and searcher efficiency trials; how data were reported and analyzed; and the methods for producing fatality estimates for the Project.

2.1.1 Areas Surveyed

Standardized carcass searches were conducted at a sample of the solar collector assemblies in each unit; the perimeter of each power block (including the area below each air condensed cooling [ACC] unit; Figures 2 and 3); the “fenceline” defined as the perimeter fences for each unit (100% of the total length of fence; Figures 2 and 3); and the gen-tie and distribution lines (25% of the total length of each line from the Project fence to Wiley’s Well rest stop; Figure 4). Table 1 provides the total area of each component as well as the percent of each component that was searched.

To ensure a balanced distribution of plots in solar collector assemblies, each unit was divided into blocks, and each block was sampled using a systematic sample of 30% of pairs of rows with a random starting point. This sampling design ensures that survey plots were not spatially clumped.

2.1.2 Search Frequency and Timing

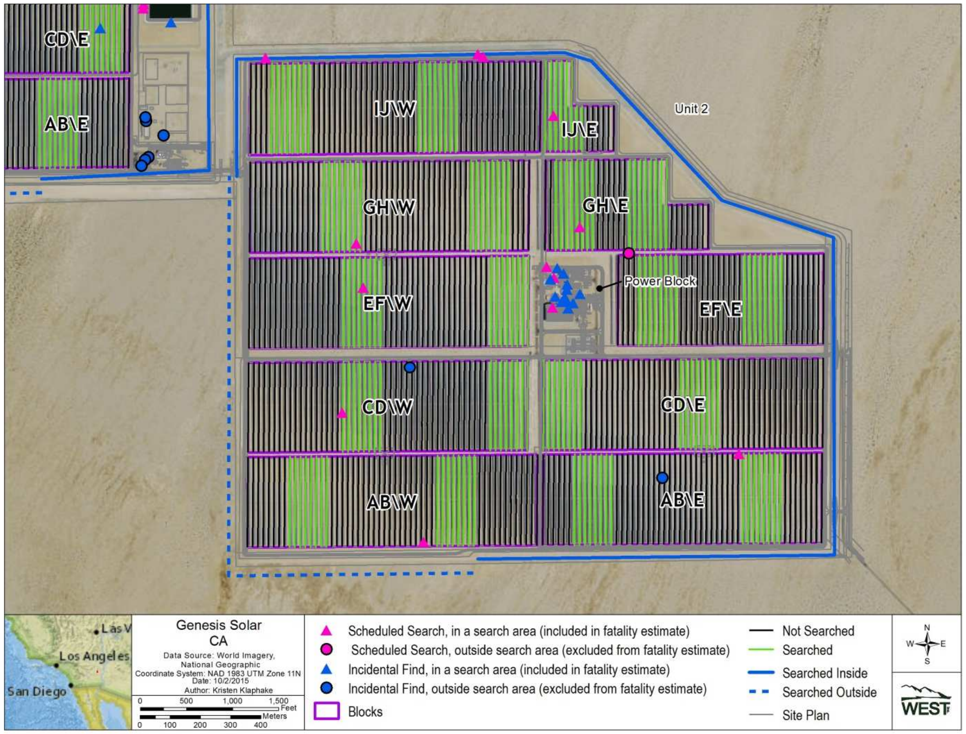
Comentado [FWS10]: Please record and report data on the time of the surveys. This will help determine if the surveys can be used to predict nocturnal vs. diurnal mig behavior.

The summer survey season includes the period from June 01 through August 30, 2015. Standardized searches occurred at 21-day intervals beginning June 01, 2015. All project components included in standardized searches were surveyed four times.

The average summer search interval was 18.9 days (median 21 days) for all Project components included in standardized carcass searches. Slight variation in search interval was anticipated due to weather and logistical delays.

Comentado [FWS11]: Please discuss the effect of the long search interval in relation to the carcass persistence trial data.

Figure 2. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance) at Unit 1 of the Genesis Solar Energy Project summer (June 01 – August 30) 2015.



Data Source: World Imagery, National Geographic
Coordinate System: NAD 1983 UTM Zone 11N
Date: 10/2/2015
Author: Kristen Klaphake

Figure 3. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance) at Unit 2 of the Genesis Solar Energy Project during summer (June 01 – August 30) 2015.

Table 1. Areas included in standardized carcass searches at the Genesis Solar Energy Project during summer (June 01 – August 30) 2015.

Project Component	Total Size	Units	Percent of Component Searched
SCAs	920	rows of solar troughs	30.4
Unit 1	460	rows of solar troughs	27.8
Unit 2	460	rows of solar troughs	33.0
ACC units	0.9	hectares	100
Power block (perimeter)	0.8	kilometers	100 of perimeter
Evaporation ponds	3.1	hectares	100
Distribution line	8.4	kilometers	25.0
Generation Tie line	8.4	kilometers	25.0
Fence	14.5	kilometers	100

Comentado [FWS12]: While 100% of the power block perimeter is being searched, the number of incidentals documented inside the structures indicate actual surveys should take place inside the perimeter. This is somewhat misleading to say 100% is surveyed.

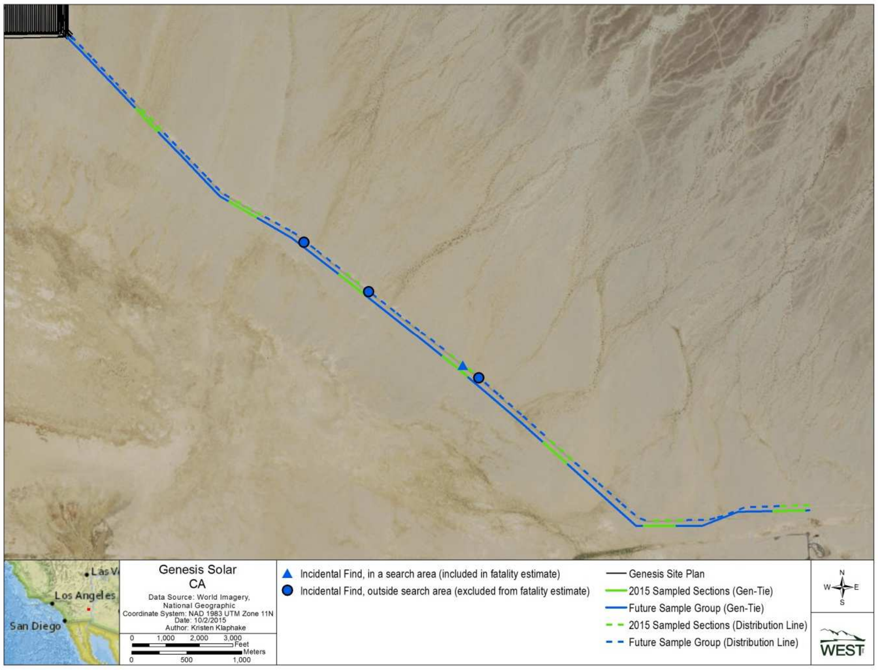


Figure 4. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance activities) along the distribution and generation tie lines and Project access road at the Genesis Solar Energy Project during summer (June 01 – August 30) 2015. Detailed maps of detections are presented in Appendix C.

2.1.3 Search Methods

Standardized carcass searches were performed by CEC- and BLM-approved biologists, in accordance with methods outlined in the BBCS.

Within the solar collector assemblies, 280 solar troughs (30.4% of the total number of troughs) were surveyed by vehicle. Biologists slowly drove (≤5 mph) parallel to troughs and centered between rows, searching ahead and to the driver's side of the vehicle for bird and bat carcasses. Biologists scanned out to a perpendicular distance of approximately 30 m, or the ground area encompassing two rows of solar troughs.

At each power block, biologists slowly walked around the entire perimeter looking for dead and injured birds and bats, and used binoculars to scan interior portions of the powerblock. Beneath ACC units, biologists walked four evenly-spaced transects (approx. 15-m apart) through the gravel. The search area for the power block is defined as the 0.8-km perimeter of each power block, and the area of the interior power block that was available for visual inspection from the periphery.

At each evaporation pond, biologists walked the entire perimeter looking for dead and injured birds and bats on the ground, in the netting, and in the pond below the netting. Binoculars or a spotting scope were used to scan across the top of the netting and the surface of each pond.

The entire length of fenceline (approximately 12 miles) was searched by vehicle. Biologists searched an approximately 1.5 to 2.5 miles (2.4 km) along drivable sections of the outside of the fence, and the remaining 9.5 to 10.5 miles (16.9 km) were surveyed from the inside of the fence (Figures 2 and 3). Travel speed was below five mph while searching.

The gen-tie and distribution lines were each surveyed using a 30-m wide strip transect (i.e., 15 m of ground on either side of the overhead line). A 25% sample of both lines from the Project fence to the Project outer gate located near the Wiley's Well Road rest stop were searched for carcasses. Biologists slowly walked every fourth 300-ft segment of each line, scanning for dead or injured birds or bats within 15 m (49.2 ft) of the transect line. Given the location of the lines relative to the road, detections found in the strip transects below overhead lines could be caused by collision with an overhead line, vehicles along the road, or some combination of both.

Once a carcass was detected, it was then photographed, and data were recorded according to specifications outlined in section 6.7 of the approved Genesis BBCS. Carcasses were then retrieved from their location on the ground, labeled, and placed in a freezer on site.

Suspected cause of death was assigned based on evidence available on the detection, evidence available on the Project infrastructure, and proximity of a detection to Project infrastructure. Detections that had evidence of scavenging and lacked evidence on Project infrastructure were assigned as "unknown" because it can't be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact

Comentado [FWS13]: Please explain details about how/when the processing occurred in relation to when carcasses were detected – especially with regard to unknown identifications.

Comentado [FWS14]: The Servicde disagrees with this assumption. If it's under the line, the better assumption is that it was caused by the line and a scavenger subsequently discovered the carcass.

(i.e., no evidence of scavenging), located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines), and had evidence of injury on the detection had a suspected cause of death attributed to the respective Project component. However, it should be noted that there is uncertainty associated with cause of death assignments because no events were directly observed.

2.2 Carcass Persistence Trials

Carcass persistence trials were conducted throughout the summer period. Carcasses from three size classes (small [0-100 g], medium [101-999], and large [1000+ g]) were used for trials. Carcass persistence results from small birds were used as a proxy for bat carcass persistence. The small size class comprised house sparrows (*Passer domesticus*) and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons (*Columba livia*), chukar (*Alectoris chukar*) and older coturnix quail, and the large size class comprised hen mallard (*Anas platyrhynchos*) and hen ring-necked pheasant (*Phasianus colchicus*).

2.2.1 Carcass Persistence Data Collection

To quantify carcass persistence rates, 15 small, 10 medium, and five large carcasses were randomly placed and monitored within the solar field (SCA's and the fence line), and the same number of each size class were placed along the gen-tie and distribution lines, for a total of 60 carcass persistence trials at Genesis during the summer 2015 season, as specified in section 6.5 of the approved Genesis BBCS. Fifteen carcasses within the Project fence (within SCAs and along the fence and perimeter of power blocks) and four carcasses along the gen-tie and distribution lines were monitored using motion-triggered digital trail cameras, while the remaining carcasses were visited on foot, for 30 days or until the carcass had deteriorated to a condition at which it would no longer qualify as a documentable fatality (i.e., a feather spot). Fewer carcasses along the gen-tie and distribution lines were monitored with cameras because of theft and vandalism concerns. Carcasses without trail cameras were visited and photographed once per day for the first four days, and then every three to five days until the end of the monitoring period. To avoid training scavengers to recognize cameras as "feeding stations", trail cameras were installed five days before specimens were placed, and fake cameras without bias trial carcasses were also placed (eight within the Project fence, and four along the gen-tie and distribution lines). Periodic ground-based checking of carcasses with trail cameras also occured to guard against misleading indicators of carcass removal, such as wind blowing the carcass out of the camera's field of view. To minimize potential bias caused by scavenger swamping (Smallwood 2007, Smallwood et al. 2010), carcass-persistence specimens were distributed across the entire Project, not just in areas subject to standard searches, and trials were initiated in small numbers on four different dates throughout the spring season.

Comentado [FWS15]: This number of carcasses is extremely low. The Service recommends increasing the number of trial carcasses to help reduce the confidence intervals on estimates.

Comentado [FWS16]: With such a low number of carcasses this is unlikely to be a problem.

2.2.2 Estimating Carcass Persistence Times

Measurements of carcass persistence rates were subject to censoring. In this context, censoring refers to the instance when a value (e.g. days a carcass is present before being removed) may not be known exactly, but is known to be within a finite range. For example, suppose a carcass was checked on day 7 and was present, and was checked again on day 10, but was found to be missing. The exact time until removal is unknown; however, it is known that the carcass became unavailable at some point between 7 and 10 days. This carcass would be considered "interval censored". Similarly, if a carcass lasts the entire 30-day trial period, that carcass is "right censored"— it is known that the carcass lasted at least 30 days, but it may have persisted longer. Because carcass persistence data were censored, persistence was analyzed using methods that can accommodate censored data and still produce unbiased estimates of the probability of persistence (Therneau 2015, Thernaur and Grambsch 2000).

Comentado [FWS17]: Please describe the interval that carcasses were checked. Is there a reason that they are not checked daily, particularly during the first week?

Comentado [FWS18]: Please clarify how censored data were analyzed and how the analytical methods affected the results. The referenced book is not available to the reader. How does the method affect the effective search interval?

USGS-developed fatality estimator software (Huso et al. 2012) was used to fit survival models to the censored carcass persistence data. There were four distributions implemented in survival models used to estimate the probability a carcass is unscavenged and available to be found at the end of the search interval (*r)*: exponential, Weibull, loglogistic, and lognormal. These four distributions exhibit varying degrees of flexibility in order to model a wide variety of distributions of persistence time. Akaike's Information Criterion adjusted for sample size (AICc; Akaike 1973) was used to rank the fit of each survival model to censored carcass persistence data.

2.3 Searcher Efficiency Trials

Searcher efficiency trials were conducted throughout the summer period. Carcasses from three size classes (small, medium, and large) were used for trials. Searcher efficiency results from small birds were used as a proxy for bat detection. The small size class comprised house sparrows and 2-3 week old coturnix quail, the medium size class comprised rock pigeons, chukar, and older coturnix quail, and the large size class comprised hen mallards and hen ring-necked pheasants.

2.3.1 Searcher Efficiency Data Collection

A total of 60 searcher efficiency trials (15 small birds, 10 medium birds, and five large birds within SCAs, power blocks, and along the perimeter fence, and the same number of each size class along the gen-tie and distribution lines) were placed at the Project during the 2015 summer season, as specified in section 6.4 of the approved Genesis BBCS. Locations for trials were chosen by taking a randomized sample of all locations included in standardized carcass searches. Trials were placed in various vegetation heights and in areas that had different soil and vegetation colors and values to represent the range of conditions under which searches occur. They were placed in all areas where standardized searches occur except the evaporation ponds.

Comentado [FWS19]: The Service proposed larger sample sizes for carcass persistence and searcher efficiency trials. Hence, has this been evaluated as adequate to determine searcher efficiency for a single strata? Please provide justification for small sample size.

2.3.2 Estimating Searcher Efficiency

Comentado [FWS20]: Is searcher efficiency tested for each observer? Please provide these results along with an indication of variation in searcher efficiency across observers.

There were not sufficient data for the summer season to assess whether searcher efficiency differed by Project component (e.g., SCAs/fence/power block [solar field] versus gen-tie/distribution line [overhead lines]), so searcher efficiency was assumed to differ between the two areas and was estimated separately for the solar field and overhead lines. The nearly complete lack of vegetation cover in the solar field suggests that searcher efficiency may be higher in the solar field than along the overhead lines where vegetation cover is greater. If this hypothesis is true, accounting for this difference in searcher efficiency across Project components will be important for producing accurate fatality estimates at the end of the monitoring year.

To evaluate hypotheses regarding differences in carcass detectability among carcass size and visibility classes, logistic regression models were fit to searcher efficiency data and AICc was used to compare models. Models including effects of carcass size (3 classes), season (spring, summer) and visibility index (2 classes) were compared to each other and a null model. The two visibility classes present at the Project site are: easy (defined as ≥ 90% bare ground [BG]; vegetation <6" tall) and moderate (defined as 26-89% BG; vegetation <6" tall). However, within the solar field the moderate visibility class has a very limited spatial extent (approximately 10%) due to management aimed at minimizing vegetation cover and thus, was represented by only two trial carcasses during the reporting period. Rather than eliminating the two carcasses in the moderate class from the analysis of searcher efficiency, we assumed there were no differences in searcher efficiency between the two visibility classes in the solar field this summer, and the set of candidate models for searcher efficiency (within the solar field only) did not include tests of the hypothesis that searcher efficiency varied between visibility classes. The spatial extent of the moderate visibility class in the solar field is roughly equal to its representation in the summer sample of searcher efficiency carcasses (8 of 60 or 13.3%).

Comentado [FWS21]: In the Spring report, this was going to be tested with further samples. Please explain the plan to address potential differences in detectability due to visibility class. We are concerned that injured or stranded birds may seek out areas with more cover as a limited shelter. This could result in bias if the moderate visibility class is not adequately tested for searcher efficiency.

Comentado [FWS22]: This seems to be changing over time. Conditions had changed considerably during our last visit from my previous visit last summer. How is this being tracked? Please explain how changing conditions will be addressed in future surveys.

Once the best model was chosen and appropriate classes identified, searcher efficiency, or the proportion of carcasses detected, *p,* was calculated for each class using the following equation:

$$p = \frac{Number\ of\ Carcasses\ Observed}{Number\ of\ Carcasses\ Available}$$

The data for this analysis included all searcher efficiency trial carcasses from the spring and summer 2015 season, because model selection results indicated no differences in searcher efficiency by season.

2.4 Fatality Estimator

Fatality rate estimation is a complex task due to several variables inherent to every fatality monitoring study. Carcasses may persist for variable amounts of time due to local scavenger activity or environmental conditions leading to carcass degradation over time. Carcasses and feather spots are also detected with varying levels of success based on carcass characteristics and ground cover (e.g., vegetated areas underneath the gen-tie and distribution lines versus cleared areas beneath SCAs). For these reasons, it is generally inappropriate to draw conclusions based on the raw number of fatalities alone. The desire to estimate fatalities given these variables has driven the development of several statistical methods for estimating fatalities (e.g., Smallwood 2007, Huso 2010, Korner-Nievergelt 2011). All of these fatality estimation methods share a similar underlying model. Generally, the fatality estimation for a given site may be written as:

$$F=C/rp,$$

where F is the total number of fatalities, C is the number fatalities detected and included in fatality estimation, r is the probability a carcass is unscavenged and available to be found at the end of the search interval, and p is the probability of detecting a carcass (Huso 2010).

All fatality estimates were calculated using the Huso estimator, as well as 90% confidence using bootstrapping (Manly 1997). Bootstrapping is a computer simulation technique that is useful for calculating point estimates, variances, and confidence intervals for complicated test statistics. A total of 1,000 bootstrap replicates were used. The lower 5th and upper 95th percentiles of the 1,000 bootstrap estimates provide estimates of the lower limit and upper limit of an approximate 90% confidence interval on all estimates.

Comentado [FWS23]: Please describe what was bootstrapped and how. The table in the appendix is difficult to understand without a better understanding of the bootstrapping methods.

2.5 Incidental Reporting

Some detections were outside standardized search areas, or were within search areas but not observed during standardized searches. Such detections were found by WEST avian biologists and operational personnel and were considered “incidental” detections. When found by operational personnel, these detections were reported to WEST avian biologists for documentation. Data on incidental detections are reported here, as well as in the SPUT Avian Injury and Mortality Report Forms June – August 2015. All detections made in search areas were included in fatality estimates, regardless of whether they were detected incidentally or during searches.

3.0 MONITORING RESULTS

3.1 Summary of Avian Detections

During summer 2015, a total of 60 detections (including stranded birds, incidental detections, and bats) of 32 identified species were recorded (Table 2). The most numerous detection of an identified species was of brown-headed cowbird (*Molothrus ater*), and greater roadrunner (*Geococcyx californianus*), each with five detections. Most detections (n = 22, or 36.7% of total detections) occurred at powerblocks (Figures 2, 3; Tables 2, 3, and 4). Twenty-four (40.0%) detections were made during standardized carcass searches and 36 (60.0%) were documented as incidentals with most of these (n = 17) in the powerblock.

Table 2. Number of individual detections (those made during standardized carcass searches and incidentally), by species and component, during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California. SCA = solar collector trough.

3.2 Temporal Patterns of Avian Detections

The number of detections recorded daily during summer 2015 ranged from zero to five (Figure 5). The period from June 01 to August 30 was characterized by peaks in detections with highs on June 29, July 2, and August 17. The fewest detections in any calendar month was July. The number of detections per day represents those discovered during standardized carcass searches and incidentally.

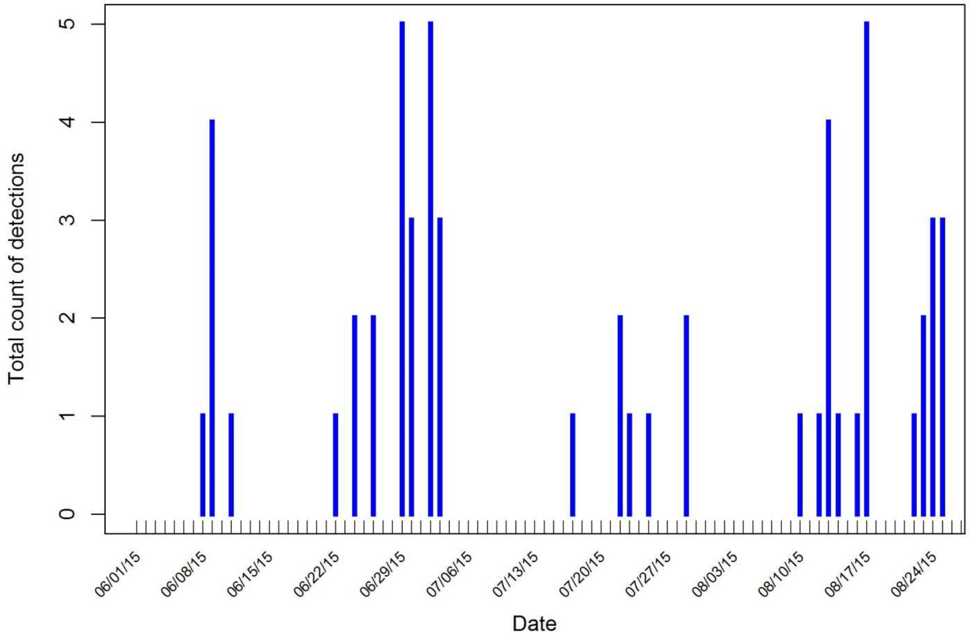

Figure 5. Total number of detections by date during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California.

3.3 Spatial Distribution of Avian Detections

Comentado [FWS24]: Spatial distribution of different taxonomic groups should be discussed, particularly as more data come in.

3.3.1 Detections by Project Component

During summer 2015, detections were documented from Project buildings, the perimeter fence, gen-tie and distribution lines (overhead lines), the power block or ACC unit within the power block, evaporation ponds, and SCAs (Tables 2, 3, and 4). Of the 60 detections within the solar units, 21 (35.0%) were detected in Unit 1, and 29 (48.3%) were detected in Unit 2.

Comentado [FWS25]: This doesn't add up. There were 55 avian detections and 5 bat detections. Should the name of this section be different?

Table 3. Total detections by Project component and detection category during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California.

Project Component	Carcass search	Incidental	Percent of Total
Buildings	0	6	10.0
Fence	4	0	6.7
Overhead lines	0	4	6.7
Ponds	5	3	13.3
Power Block	5	17	36.7
SCA	10	6	26.7
Percent of Total	40.0	60.0	100.0

Table 4. Total detections (including incidentals) by Project component and suspected cause of death during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California.

	Suspected Cause of Death*						
Project Component	**Collision**	**Drowned**	**Entangled**	**Other**	**Predation**	**Unknown**	**% of Total**
Fence	0	0	0	2	0	2	6.7
Other	1	0	0	1	0	4	10.0
Overhead lines/road	2	0	0	1	0	1	6.7
Pond	1	0	2	3	0	2	13.3
Powerblock	7	1	0	8	0	6	36.7
SCA	4	0	0	8	1	3	26.7
% of Total	25.0	1.7	3.3	38.3	1.7	30.0	100.0

* Suspected cause of death was assigned based on evidence available on the detection, evidence available on Project infrastructure, and proximity of detection to Project infrastructure. Detections that had evidence of scavenging and lacked evidence on Project infrastructure were assigned as "unknown" because it can't be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) and had evidence of injury on the detection had a suspected cause of death attributed to the respective Project component. However, ~~it should be noted that~~in the absence of completed necropsy, there is ~~substantial~~ some uncertainty associated with cause of death assignments because no events were directly observed.

Comentado [FWS26]: Was proximity to project features evaluated? Please describe how this information was utilized. Proximity distances may provide insights into which features may pose the greatest risks.

Comentado [FWS27]: This blanket categorization is problematic. Other visual evidence may allow determination of a suspected cause of death despite evidence of scavenging (i.e., smudge on mirror). The presence of some scavenging should lead to an automatic categorization. Small levels of scavenging can be easily distinguished as not the cause of death (i.e., arthropod scavenging and minimal raven scavenging). Also, other indicators of the cause of mortality should also be considered (dust smudges, species identification, etc). This should not be a blanket categorization.

3.3.2 Feather Spot Detections

Twelve (20.0%) of the 60 detections made during summer 2015 consisted only of feather spots. Along the fence, three of four total detections (75.0%) were feather spots. No detections along the overhead lines and road or the evaporation ponds were feather spots. Three of 22 total detections (13.6%) at the powerblocks were feather spots. Six of 16 total detections (37.5%) at SCA's were feather spots.

3.4 Detections of Stranded Birds

There were no detections of stranded or injured birds during the 2015 summer season.

3.5 Summary of Bat Detections

Five bats were detected during the summer season. Idenitified species included Mexican free-tailed (*Tadarida brasilinesis*; 1), and canyon bat (*Pipistrellus hesperus*; 2; Table 2).

3.6 Carcass Persistence Trials

Data from carcass persistence trial carcasses were available from spring and summer at the solar field and overhead lines (n = 30 each or 120 total). Of these, only seven trials were not in easy visibility habitats, so visibility was not included as a covariate in the carcass removal models. Preliminary analysis using AICc suggested that both season and location (lines vs. solar field) were important predictors of carcass persistence, but when the data were separated by location, season was only important for carcasses within the solar field. Therefore, two carcass persistence models were fitted to two different sets of data: 60 carcasses from spring and summer were used to estimate carcass persistence along overhead lines, and 30 carcasses from summer only were used to estimate carcass persistence within the solar field.

Comentado [FWS28]: The searcher efficiency results suggest that carcass persistence may be lower along the fence.

Using carcass persistence data from 2015 spring and summer seasons as outlined above, survival models were compared for relative quality using the corrected AICc score, as suggested in Huso (2010). The AICc score provides a relative measure of model fit and parsimony among a selection of candidate models. The model with lowest AICc is typically chosen as the "best" model relative to other models tested; however, any model within two AICc points of the best model is considered competitive with the best model (Burnham and Anderson 2004).

For data collected at SCAs, the top two models had ΔAICc values <2. Ultimately, the loglogistic model that included an effect of carcass size was chosen as the most parsimonious of the top models. The chosen model predicted that 52% (45 – 64%) of small carcasses, 92% (76 – 96%) of medium carcasses, and 100% of large carcasses persisted for a standard 21-day search interval. Mean removal time for small carcasses in the SCAs was 8.0 days, 35.1 days for medium carcasses, and was not estimated for large carcasses given the nearly perfect persistence rate (no removal was observed; Figure 6).

Comentado [FWS29]: Please provide the median removal time along with a figure showing the removal curve produced by the model.

For data collected along the overhead lines, the top six models had ∆AICc values <2. Ultimately the lognormal model with an effect of carcass size was chosen as the most parsimonious top model. The chosen model predicted that 14% (9 – 20%) of small carcasses, 59% (42 – 74%) of medium carcasses, and 41% (26 – 58%) of large carcasses persisted for a standard 21-day search interval. Mean removal time along overhead lines for small carcasses was 0.8 days, for medium carcasses was 12.8 days, and for large carcasses was 4.6 days (Figure 6).

Comentado [FWS30]: See above.

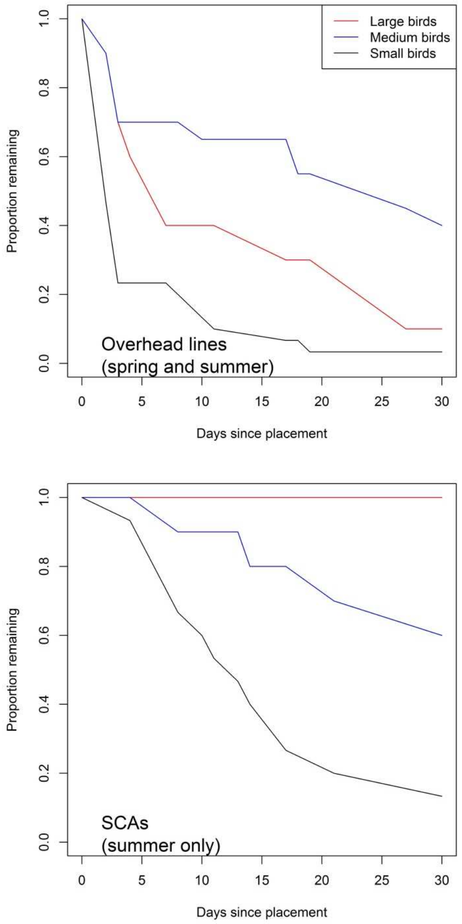

Figure 6. Proportion of trial carcasses remaining as a function of days since placement and carcass size class during the summer 2015 season at the Genesis Solar Energy Project, Riverside County, California. Modeling of carcass persistence data from overhead lines suggested no effect of season, so sample size used to produce the overhead lines panel was n = 30, 20, and 10 for small, medium, and large size classes, respectively. Modeling of carcass persistence data from the solar field (SCAs) suggested an effect of season, so sample size used to produce the SCA panel was n = 15, 10, and 5 for small, medium, and large size classes, respectively.

3.7 Searcher Efficiency Trials

During the 2015 summer season, a total of 60 searcher efficiency trials (30 small, 20 medium, and 10 large birds) were placed at the Project. Overall, 21 trials were placed in the SCAs, six trials were placed along perimeter fences (inner and outer perimeters), and three trials were placed at power blocks (along perimeter and beneath ACC units). Fifteen trials were placed along the gen-tie and 15 were placed along the distribution lines. Fifty-one trials were available to be found, and nine trials disappeared before the searcher efficiency trial began (three in the SCAs, four along the fence, one along the distribution line, and one along the gen-tie line).

Comentado [FWS31]: This section is difficult to follow. It's not clear what was done and how the "unavailability of carcasses" is affecting the results. Please clarify and provide a suggestion on how to address the carcass removal problem.

Comentado [FWS32]: How was this broken down by project component, visibility categories and size classes? Please provide a table to make it easier to understand to the numbers in the text.

Comentado [FWS33]: Only three at the power blocks, combined? This is an issue given all of the incidentals at these components.

Con formato: Resaltar

Con formato: Resaltar

Con formato: Resaltar

Comentado [FWS34]: How much time elapsed between setting out the carcasses and the trials. This seems like another issue that is not corrected for.

What sizes were the nine that disappeared?

Searcher efficiency may be high, but it persistence is not, then data are being missed/lost. It seems impossible to determine if the carcass that were missing disappeared before or after the searcher did their searches.

There seems to be differential carcass persistence that may be affecting the searcher efficiency trials.

In the solar field (SCAs + fence + powerblocks), the null model was chosen as the best model to estimate searcher efficiency, suggesting no effect of carcass size, season, or visibility class. Thus, data from spring and summer searcher efficiency trials, all carcass class sizes, and both visibility classes were pooled for the following estimate of searcher efficiency. Searcher efficiency rate in the solar field was 91.8% (86.0 – 98.0%), or 45 found of 49 available to be found.

Con formato: Resaltar

Along overhead lines, the model that included an effect of carcass size, but not season or visibility class, was chosen as the best model. Thus, data from spring and summer trials and both visibility classes were pooled for the following estimates of searcher efficiency along overhead lines: 53.6% for small birds (39.0 – 68.0%; 15 found of 28 available to be found), 100% for medium birds (19 found of 19 available), and 100% for large birds (10 found of 10 available). Although carcass size influenced searcher efficiency, searcher efficiency was relatively high over all carcass size classes (77.1%).

Comentado [FWS35]: Does this make sense statistically?

Con formato: Resaltar

Comentado [FWS36]: The highlighted numbers don't add up.

3.8 Fatality Estimates

Fatality estimates were calculated separately for each component (SCAs, power blocks, fence, evaporation ponds, and overhead lines/road). Ultimately, no detection was excluded from the fatality analysis because it was estimated to be older than the 21-day search interval (Huso 2010), and 16 detections were excluded because they were found outside standardized search areas. Of the 36 detections that were found incidentally, 14 were in a standardized search area and included in the fatality analysis, so 22 incidental detections were excluded from the fatality analysis. However, all detections made during summer are reported in Table 2.

Comentado [FWS37]: Please provide an additional summary tables with the following information for each component and for the entire facility: carcasses detected, estimated fatalities; 90% CI. An additional table with the same information for each size category is also requested.

Using the Huso (2010) fatality estimator model, during the summer period 2015, there were an estimated total 100 carcasses (90% CI: 81 - 145) at the Project. Of these, 53 carcasses (53%) were estimated for the SCAs, 8 carcasses (8%) were estimated for the fence, 9 carcasses (9%) were estimated for evaporation ponds, 23 carcasses (23%) were estimated for power blocks, and 7 carcasses (7%; CI: 6 – 21) were estimated for the overhead lines and project road. An estimated 93 (93%; CI: 66-126) carcasses (~~0.0~~50/1000 acres, 0.37/nameplate MW) occurred for all components associated with both solar units (SCAs, power block, evaporation ponds, and along the perimeter fence, combined). A complete list of estimates for each Project component and carcass size class with confidence intervals is presented in Appendix B.

Comentado [FWS38]: Given the size of utility scale projects "per 1000 acres seems more appropriate.

4.0 DISCUSSION

The 2015 summer season represented the second season of standardized monitoring at Genesis per the BBCS. Searcher efficiency trials and carcass removal trials were conducted concurrently at the SCAs, power blocks, fencelines, and along the gen-tie and distribution lines. Data from these trials were used to produce fatality estimates adjusted for searcher efficiency and carcass persistence bias. Although these estimates were produced from a statistically robust sample, only limited inference may be drawn from a single season of data. These results should be considered preliminary because estimating carcass persistence, searcher efficiency, and adjusted numbers of fatalities within each season represents information based on a limited sample size. As more data are collected throughout the monitoring year (and additional quality assurance/quality control measures occur, for example characterizing feather spots to species or size class), data from all seasons may be pooled. At that time, data will be tested for seasonal differences retrospectively using an information-theoretic approach, but because seasonal estimates will be produced from the much larger annual data set, they may differ from what is reported here because they are based on a larger, more informative sample.

Comentado [FWS39]: This is counter-intuitive. If there are inadequate samples to give a seasonal estimate for searcher efficiency, how will this be possible from the complete annual dataset. The number of carcasses should probably be increased based on a power analysis, so that seasonal estimates can be completed.

4.1 Carcass Persistence and Searcher Efficiency Trials

The degree to which carcasses persist on the landscape depends on a variety of factors reflecting seasonal and inter-annual variation in habitat, climate, and the scavenger community. The composition and activity patterns of the scavenger community often vary seasonally as birds migrate, new juvenile birds and mammals join the local population, and mammalian scavengers variably hibernate or estivate. The scavenger community may also vary substantially from year to year because of variation in annual reproduction and survival related to changes in landscape condition. Climatic conditions that vary seasonally and annually also may contribute to variation in carcass decay and removal rates due to variation in temperatures, solar insolation, wind patterns, and the frequency of flooding events. Thus, rates of carcass persistence reported here should be interpreted cautiously as they may change over the coming months.

Searcher efficiency was influenced by carcass size, but it is not yet clear if there may be an effect of habitat visibility class due to limited sample sizes. In the SCA's, searcher efficiency was high regardless of carcass size and this is likely influenced by the limited vegetation cover beneath solar troughs. Beneath overhead lines outside the Project fence vegetation cover is higher, but our analysis did not support the hypothesis that visibility class is a factor in searcher efficiency along the lines. Carcass size influenced searcher efficiency, but searcher efficiency was relatively high over all carcass size classes (77.1%).

Comentado [FWS40]: This supports putting out more trials.

Searcher efficiency trials for this Project will be repeated seasonally. The desert landscape in which this Project is located generally changes little with the seasons, save for brief periods following winter and spring rains when floods may occur and blooming plants may flourish. A recent meta-analysis involving data from more than 70 wind-energy projects suggested that including habitat visibility class as a predictive variable generally eliminated any otherwise

Comentado [FWS41]: Summer monsoons.

apparent seasonal effects on searcher efficiency (Smallwood 2013). Further, the possibility exists that searcher efficiency varies seasonally in some cover types but not others. Data from searcher efficiency trials conducted over the coming seasons will therefore continue to be tested for effects of habitat visibility class rather than effects of season.

4.2 Distribution of Fatalities and Fatality Estimates

The number of detections was highest during the early and late summer monitoring period and lowest during July. However, because this report includes detections made during carcass searches and incidental detections reported by Genesis site personnel between searches, patterns may reflect the 21-day search interval during summer more than any patterns in bird activity at the Project.

Comentado [FWS42]: This suggests that the Spring and Fall search periods are too short and the migratory seasons extend into the Summer search period. The low carcass persistence suggests that the search interval should be weekly year round to provide better estimates of carcass persistence.

Composition of summer detections included avian species from 13 guilds. No single guild comprised a large number of detections: the most common was blackbirds/orioles (eight detections or 14.5% of all avian detections). Shorebirds and waterbirds/waterfowl were represented by six (10.9%) and seven (12.7%) detections, respectively. Summer was the first season in which bats were detected.

Con formato: Derecha

Detections attributed to an unknown cause accounted for approximately 30% of all detections during the 2015 summer season, and the distribution of the unknown cause detections varied by project component with the highest percentage of unknowns (66.7%, or 4 of 6 total detections) occurring in association with Project components that are not included in standardized carcass searches (e.g., buildings). Of the 18 detections attributed to an unknown cause, 4 (22.2%) were feather spots. Determining a cause of mortality from a feather spot is challenging because there is rarely visible evidence available on which to determine a cause of death. Thus, feather spots with an unknown cause of mortality could be encountered anywhere birds occur, and an unknown cause of a sizeable proportion of the carcasses is not unique to the Project. Further, the presence of feather spots among the detections for the Project may inflate the fatality estimate based on the potential for multiple feather spots resulting from one fatality to be counted separately if feathers are blown around the site or scattered by predators (e.g., plucking by ravens), feather spots resulting from predation not associated with the facility, or other causes. However, feather spots are included in the analysis here to provide a more conservative estimate of fatality.

Comentado [FWS43]: What fraction of these unknown detections are feather spots?

Comentado [FWS44]: We don't agree with this statement. This is unknown. Feather spots may be more mobile, but as far as I know there have been no studies on whether they "multiply" and cause bias. If there has, please provide a reference. It is possible that feather spots could accumulate along fences, but in general, they are just as likely to migrate into a survey area as they are to leave. If this is a significant problem, then I recommend shorter search intervals and more complete coverage of the project site.

1.0 Introduction

This draft Bird Monitoring Study was prepared for the Mojave Solar Project (MSP or project) to address potential impacts to birds from operation of the project, and to be in compliance with the California Energy Commission's (CEC) Conditions of Certification (COC). Specifically, COC BIO-17 states that the project owner shall prepare and implement a study to monitor the death and injury of birds from collisions with facility features such as reflective mirror-like surfaces, from heat, and from bright light from concentrated sunlight (CEC, 2010). This study, therefore, addresses potential avian mortalities during MSP operation.

The U.S. Fish and Wildlife Service (USFWS) established methods and guidelines for monitoring bird mortalities at solar power facilities (Nicolai et al., 2011). These methods and guidelines are incorporated into this study and modified to establish a protocol for data acquisition and carcass collection that achieves a 100 percent study area survey.

1.1 Purpose

The purpose of this study is to outline a scientific and repeatable method to monitor the potential impact of parabolic trough solar technology on birds. Therefore, the methods presented in this plan will be used in a controlled study of deaths of and injuries to birds as a result of their interaction with project features. Replicable data acquisition procedures and carcass collection protocols, including a proposed schedule of carcass searches are outlined in this plan. These measures are designed to conform to the requirements of COC BIO-17:

> COC BIO-17: The project owner shall prepare and implement a Bird Monitoring Study to monitor the death and injury of birds from collisions with facility features such as reflective mirror-like surfaces and from heat, and bright light from concentrating sunlight. The study design shall be approved by the CPM in consultation with CDFG and USFWS, and shall be incorporated into the project's BRMIMP and implemented. The Bird Monitoring Study shall include detailed specifications on data and carcass collection protocol and a rationale justifying the proposed schedule of carcass searches. The study shall also include seasonal trials to assess bias from carcass removal by scavengers as well as searcher bias.

This study includes adaptive management approaches to reduce the potential for negative impacts due to changing situations (e.g. seasonal fluctuations in bird use). Once approved by the CEC's Compliance Project Manager (CPM) and Staff, in consultation with the California Department of Fish and Wildlife [CDFW] and USFWS, this study will be implemented and incorporated into the project's Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP) (CEC, 2010).

1.2 Project Background

The MSP is a solar electric generating facility located in San Bernardino County, California, approximately 20 miles west of Barstow, California (Figure 1). Site access is from Harper Lake Road off of Highway 58. The project sits on private property historically occupied by the Lockhart Ranch complex that once served as an agricultural and cattle center.

The MSP uses solar parabolic trough technology to warm a heat transfer fluid (HTF) which converts water to steam to power a steam turbine electrical generator at twin solar fields—Alpha, approximately 950 acres, and Beta, approximately 815 acres. Solar fields comprise approximately 70% of the total project area while power blocks comprise about 3% of the area. The remainder of the project area consists of drainage improvements, evaporation ponds, a substation, and other shared elements. Tortoise-exclusion and security fencing have been installed around the entire project perimeter.

The electrical output from each solar field will join at an onsite transmission line interconnection substation.

The expected operating life of the project is between 30 and 40 years. Whenever the facility is closed, whether temporarily or permanently, the closure procedures outlined in the CEC Decision (CEC, 2010) will ensure compliance with applicable laws, ordinances, regulations, and standards (LORS).

2.0 Roles and Responsibilities

MSP will be responsible for implementing the methods presented in this study. MSP will obtain all applicable state and federal permits and adhere to their requirements. The current reporting requirements for the temporary "Migratory Bird Special Purpose Utility Salvage Permit - Solar," issued August 15, 2013, are summarized in Appendix A.

3.0 Regulatory Framework

This section identifies applicable LORS, and the protected avian species that have the potential to occur on the project site

3.1 Protected Species

Special-status and sensitive biological resources include animal species that have special recognition by federal, state, and/or local conservation agencies and organizations as endangered, threatened, rare, or otherwise of concern.

The birds listed in Table 1 are protected by state or federal regulations (CDFW, 2013a; Mojave Solar LLC, 2009; USFWS, 1973), or are recognized as sensitive or of concern due to declining or limited populations (USFWS, 2008). The presence of year-round water at the Harper Dry Lake Watchable Wildlife Area, adjacent to and north of the MSP Beta Solar Field boundary, attracts a number of the bird species listed in Table 1. Preconstruction and construction surveys have detected sensitive avian species at the MSP site (Figure 2). However, it should be noted that the vegetation within the MSP site proper has been removed during construction, presumably greatly reducing the potential of the project area to attract many avian species. It is also noted that most observations listed in Table 1 are historical and likely do not represent current bird occupancy of the MSP and vicinity.

Table 1
Special-Status Bird Species at or in the Vicinity of MSP

Species	**Sensitivity Status**[a]	**Breeding Confirmed at MSP and Nearby Vicinity**	**Potential To Occur at MSP and Vicinity**[b]
American white pelican (*Pelecanus erythrorhynchos*)	CDFW-SSC (nesting colony)	No	Observed at the adjacent Harper Dry Lake
Double-crested cormorant (*Phalacrocorax auritus*)	CDFW-WL (nesting colony)	No	Observed at the adjacent Harper Dry Lake
White-faced ibis (*Plegadis chihi*)	CDFW-WL (nesting colony)	No	Observed at the adjacent Harper Dry Lake
Sharp-shinned hawk (*Accipiter striatus*)	CDFW-WL (nesting)	No	Observed wintering at MSP
Cooper's hawk (*Accipiter cooperii*)	CDFW-WL (nesting)	No	Observed wintering at MSP
White-tailed kite (*Elanus leucurus*)	CDFW-FP (nesting)	No	High potential to occur during migration; however, species not observed to date
Northern harrier (*Circus cyaneus*)	CDFW-SSC (nesting)	Yes	Breeding confirmed during spring 2011
Swainson's hawk (*Buteo swainsoni*)	CESA-Threatened, USFWS-BCC, USFS-S (nesting)	No	Observed migrating through MSP
Ferruginous hawk (*Buteo regalis*)	USFWS-BCC, CDFW-WL (wintering)	No	Observed wintering at MSP
Golden eagle (*Aquila chrysaetos*)	BGEPA, CDFW-FP, BLM-S, CDFW-WL, USFWS-BCC (nesting and wintering)	Yes	Observed known breeding pair north of MSP; pair foraged around MSP

Table 1
Special-Status Bird Species at or in the Vicinity of MSP

Species	Sensitivity Status[a]	Breeding Confirmed at MSP and Nearby Vicinity	Potential To Occur at MSP and Vicinity[b]
Osprey (*Pandion haliaetus*)	CDFW-WL (nesting)	No	Observed at the adjacent Harper Dry Lake
Merlin (*Falco columbarius*)	CDFW-WL (wintering)	No	Observed wintering at MSP
American peregrine falcon (*Falco pereginus anatum*)	CDFW-FP, USFWS-BCC (nesting)	No	Observed wintering at MSP
Prairie falcon (*Falco mexicanus*)	USFWS-BCC, CDFW-WL (nesting)	No	Observed foraging at MSP; confirmed nesting offsite to north
Mountain plover (*Charadrius montanus*)	FESA- Proposed Threatened, CDFW-SSC, USFWS-BCC, BLM-S (wintering)	No	Observed wintering at MSP
Long-billed curlew (*Numenius americanus*)	USFWS-BCC, CDFW-WL (nesting)	No	Observed migrating through MSP
Caspian tern (*Sterna caspia*)	USFWS-BCC (nesting colony)	No	Observed at the adjacent Harper Dry Lake
California gull (*Larus californicus*)	CDFW-WL (nesting colony)	No	Observed at the adjacent Harper Dry Lake
Western burrowing owl (*Athene cunicularia hypugea*)	CDFW-SSC, USFWS-BCC, BLM-S (burrow sites and some winter sites)	Yes	Observed from 2006 to 2008; however, none have been observed since 2008
Long-eared owl (*Asio otus*)	CDFW-SSC (nesting)	Yes	Breeding confirmed during spring 2011
Short-eared owl (*Asio flammeus*)	CDFW-SSC (nesting)	No	Observed migrating through MSP

Table 1
Special-Status Bird Species at or in the Vicinity of MSP

Species	Sensitivity Status[a]	Breeding Confirmed at MSP and Nearby Vicinity	Potential To Occur at MSP and Vicinity[b]
Vaux's swift (*Chaetura vauxi*)	CDFW-SSC (nesting)	No	Observed migrating through MSP
Olive-sided flycatcher (*Contopus cooperi*)	CDFW-SSC, USFWS-BCC (nesting)	No	Observed migrating through MSP
Willow flycatcher (*Empidonax traillii*)	CESA-Endangered, USFWS-BCC (nesting)	No	Observed migrating through MSP
Vermilion flycatcher (*Pyrocephalus rubinus*)	CDFW-SSC (nesting)	Unknown	Observed during the breeding season; however, nesting could not be confirmed
Loggerhead shrike (*Lanius ludovicianus*)	CDFW-SSC, USFWS-BCC (nesting)	Yes	Breeding confirmed during spring 2011
Bank swallow (*Riparia riparia*)	CESA-Threatened (nesting)	No	Observed migrating through MSP
Yellow warbler (*Dendroica petechia breswteri*)	CDFW-SSC; USFWS-BCC (nesting)	No	Observed migrating through MSP
Brewer's sparrow (*Spizella breweri*)	USFWS BCC (nesting)	No	Observed migrating through MSP
Yellow-headed blackbird (*Xanthocephalus xanthocephalus*)	CDFW SSC (nesting)	No	Observed at the adjacent Harper Dry Lake

Table 1
Special-Status Bird Species at or in the Vicinity of MSP

Species	Sensitivity Status[a]	Breeding Confirmed at MSP and Nearby Vicinity	Potential To Occur at MSP and Vicinity[b]
Tricolored blackbird (*Agelaius tricolor*)	CDFW-SSC, BLM-S, USFWS-BCC (nesting colony)	No	Observed at the adjacent Harper Dry Lake

Adapted from Final Environmental Assessment (2011, USDOE)

[a] Sensitivity status taken from CNDDB 2011. In most instances, the sensitivity status only applies when the species is nesting or wintering.

[b] The vegetation within MSP project boundaries has been removed during construction, substantially decreasing potential nesting or wintering locations.

Following are acronyms used to identify the sensitivity status of birds listed in Table 1:

BGEPA: Bald and Golden Eagle Protection Act
BLM-S: Bureau of Land Management – Sensitive Species
CDFW-FP: California Department of Fish and Wildlife – Fully Protected Species
CDFW-SSC: California Department of Fish and Wildlife – Species of Special Concern
CDFW-WL: California Department of Fish and Game – Watch List
CESA: California Endangered Species Act
FESA: Federal Endangered Species Act
USFWS-BCC: U.S. Fish and Wildlife Service – Birds of Conservation Concern

3.2 Applicable Federal and State Regulations

The following state and federal laws and regulations apply to the "take" and/or mortality of a bird species that could occur during project operations. The term "take" means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to collect, or attempt to engage in any such conduct directed toward a listed species (50 Code of Federal Regulations [CFR] Section 10.12.).

3.2.1 Migratory Bird Treaty Act

The Migratory Bird Treaty Act (MBTA) (Title 16, United States Code [USC], Part 703) implements the provisions of treaties between the United States, Great Britain, Mexico, Japan, and the (former) Soviet Union. In addition, the MBTA enables the U.S. Secretary of the Interior to protect and regulate the taking of migratory birds, determine seasons and bag limits for hunted species, and protect migratory birds' occupied nests and eggs (16 USC 703, 50 CFR 21, 50 CFR 10). Violations of the MBTA typically result from the taking or possession (permanent or temporary) of a protected species or its parts.

For most avian species, the anthropogenic environment is unavoidable and poses species-specific risks and benefits (Erickson et al., 2005; Kristan and Boarman, 2007). Consequently, guidelines have been developed to circumvent such impacts (e.g., APLIC and USFWS, 2005), and failure to comply with these guidelines may result in MBTA permitting violations (Lilley and Firestone, 2008; CEC, 2010).

3.2.2 Federal Endangered Species Act

The Federal Endangered Species Act (FESA) requires maintenance of lists of threatened and endangered species, while affording them protections. An endangered listed species is at risk of extinction throughout all or a significant portion of its range (FESA Section 3[6]), while a threatened listed species is likely to become endangered within the near future (FESA Section 3[19]). The take of any FESA-listed endangered fish or wildlife species and most threatened species is prohibited. Take, as defined by the FESA, means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct (16 USC Section 1531 et seq.). Harm is defined as any act that kills or injures the species, including significant habitat modification (16 USC Section 1531 et seq.).

Exceptions to Section 9 take prohibitions exist under certain circumstances. For non-federal projects, Section 10 allows for the issuance of a 10(a)(1)(b) permit to take FESA-listed species during otherwise lawful activities. Without the permits or authorization by USFWS, fatality of FESA-listed species from collision, could result in enforcement action.

3.2.3 Bald and Golden Eagle Protection Act

The Bald Eagle and Golden Eagle Protection Act forbids the taking or possession of bald and golden eagles, with limited exceptions (16 USC Section 668). It is a violation to take, possess, sell, purchase, barter, offer to sell, transport, export or import, at any time or in any manner, any bald eagle, commonly known as the American eagle, or golden eagle, alive or dead, or any part, nest, or egg thereof (16 USC Section 668). Take is defined to include pursuing, shooting, shooting at, poisoning, wounding, killing, capturing, trapping, collecting, molesting, or disturbing (16 USC Section 668).

3.2.4 California Endangered Species Act

The California Endangered Species Act (CESA) prohibits take of threatened or endangered wildlife listed by the California Fish and Wildlife Commission. Under the CESA, take is defined as any action or attempt to hunt, pursue, catch, capture, or kill (California Fish and Game Code Section 2050 et seq.). Similarly, CESA allows exceptions to the take prohibition for take that occurs during otherwise lawful activities. Incidental take of CESA listed species may be authorized if an applicant submits an approved plan that minimizes and fully mitigates the impacts of the take (California Fish and Game Code Section 2050 et seq.).

3.2.5 California Fully Protected Bird Species

Before CESA was enacted, the California Legislature identified bird species for specific protection under the California Fish and Game Code. These species are fully protected and may not be taken or possessed at any time. Besides collecting for necessary scientific research and relocation of the bird species for the protection of livestock, no permits or licenses can be issued for their take. Fully protected bird species are described in Title 14, Section 3511 of the California Fish and Game Code, which states that no provision of this code or any other law shall be construed to authorize the issuance of permits or licenses to take any fully protected species.

3.2.6 California Species of Special Concern

To maintain viable populations of all native species, CDFW has designated certain vertebrate species as Species of Special Concern due to declining population levels, range limitations, and/or continuing threats that have made them vulnerable to extinction. The Species of Special Concern designation is intent on halting or reversing a species decline by calling attention to its plight and addressing concern early enough to secure its long-term viability. Species may be in initial decline or have already reached the point where they meet the criteria for listing under the CESA and/or FESA.

3.2.7 California Fish and Game Code 3503.5 (Birds of Prey)

Without CDFW authorization, Section 3503.5 bans the take, possession or destruction of any birds of prey or their nests or eggs.

4.0 Risk Assessment

Collisions with mirror arrays and interactions with evaporation ponds are aspects of the project anticipated to be the primary sources of potential mortality to birds. Collisions with buildings and electrocution are lesser potential mortality sources. These last, however, are either commonplace features on other developments (building collisions), or are pre-existing hazards (transmission lines, electrocution). Therefore, these potential hazards will not be addressed in this document, but will be incidentally recorded by project staff or the Designated Biologist.

4.1 Avian Mortality

Scant information exists about the interactions of solar facilities and bird populations (Lovich and Ennen, 2011). In general, the relationship of bird mortality to utility facilities is affected by, among other things, topography, habitat type, availability of natural perches, food and water abundance (Lovich and Ennen, 2011; McCrary et al., 1986) and facility design. Incidental avian mortality data from an adjacent facility, NextEra Solar Electric Generating Systems (SEGS), has been summarized by CEC staff between 1990 and 2012. According to the CEC, the average avian mortality per year at the SEGS facility is 8 birds (range: 0 to 110 birds).

4.1.1 Mirror Arrays

Reflective surfaces are recognized to be a greater hazard to birds than structures because: "Analysis of experimental results and observations under a multitude of conditions suggest that birds hit windows because they fail to recognize clear or reflective glass surfaces as barriers," (Klem, 1989).

Unlike the a central receiver arrangement, the parabolic troughs used by the MSP concentrate solar energy on a collector tube located only a few feet in front of the mirror, located in the focal point of the parabolic reflector. More than 99% (intercept factor) of the incoming rays are reflected on the inner site of the receiver facing the parabola, eliminating the potential to burn birds flying overhead, or even a few feet away. Collisions with mirrors and other structures appear to be the principle potential hazard on MSP.

4.1.2 Evaporation Ponds

The MSP will include four evaporation ponds (approximately 5 acres each) that have the potential to attract migratory birds. Wastewater discharged to evaporation ponds potentially contains contaminants (AECOM, 2011b) known to be harmful to birds (Duawe et al., 2000; Hui 2002; Ohlendorf and Heinz, 2011), and/or become hypersalinic through pond evaporation (René et al., 1999). As such, adaptive management actions developed through this study and an Evaporation Pond Monitoring and Adaptive Management Plan will be used to discourage or prevent birds from coming in contact with the water in the evaporation ponds (CEC, 2010).

5.0 Impact Reduction and Mitigation Measures

The CEC Decision (CEC, 2010) includes several COCs with an avian protection component. In accordance with project design, COC BIO-07 requires the project to limit disturbance during construction and operation, and to implement management and mitigation measures to counter potential adverse impacts.

5.1 Project Setting

The MSP is located mostly on previously disturbed, abandoned agricultural fields, historically used for crop production, cattle ranching, and dairy farming. The intent of choosing disturbed habitat for the project site was, in part, to limit impacts to natural vegetation that could provide habitat for wildlife, including avian species.

5.2 Avoidance and Minimization Measures

A number of measures have been developed for the MSP to minimize the potential risk to birds during project operation. These actions are proactive, intent on preventing a potential impact rather than resorting to remedial compensations enacted after the fact.

Avoidance and minimization measures include, but are not limited to the following:

- Transmission lines and electrical components follow the established guidelines to reduce the likelihood of bird electrocutions and collisions (APLIC, 2006).
- Project lighting is shielded, directional, and the lowest intensity necessary to perform work to minimize lighting impacts to Harper Dry Lake marsh and avian inhabitants.
- Worker awareness training is provided that increases understanding of potential threats to avifauna. This training aims to enhance cooperation with MSP biologists and the understanding of the need to protect wildlife.
- All trash is contained in enclosed receptacles to prevent the introduction of subsidized food sources to predators.

- Any road-kill are promptly removed from the project site.
- Avoiding pooling if watering is used for dust suppression

5.3 Corporate Policy

Mojave Solar LLC's policy is to comply with all regulatory requirements; and management and employees are committed to reducing the detrimental effects of project - wildlife interactions.

To fulfill this policy commitment, the MSP will:

- Implement and comply with the provisions of this study, per COC BIO-17 (see Section 1.1).
- Ensure all actions comply with applicable LORS and permits.
- Document bird mortalities and problem structures through active compliance monitoring.
- Provide information and resources through training of specific operational staff with bird protection objectives and the specific requirements of this study.
- Evaluate methods and apply adaptive management principals to use information gained from operation of the project to improve protection of avian species.

5.4 Resource-specific Management Plans

The CEC Decision (CEC, 2010) required the development and implementation of management plans to minimize the direct or indirect impacts of the project operations to golden eagles, common ravens, and other birds. Although each plan is resource specific, multiple bird species are construed to benefit from the actions outlined in each plan. Only those plans pertaining to project operations are summarized here.

5.4.1 Golden Eagle Territory-specific Management Plan

Two golden eagle inventories were conducted during the breeding and non-breeding seasons to determine golden eagle territory occupancy within 10 miles of the MSP (excluding Black Mountain territory). On January 28, 2011, USFWS issued golden eagle measures that supplant the need for a Golden Eagle Territory-Specific Management Plan, and this was provided to CEC on March 17, 2011 (Abengoa Solar, 2011). These measures are:

- Compensatory Lands: Agriculture. The MSP acquired 128 acres of land to make available in perpetuity for productive agricultural use. This compensation land is located directly west of the project site and will provide suitable foraging habitat for golden eagles and other bird species found within the area.
- Compensatory Lands: Wildlife. The MSP acquired 118.2 acres of land suitable for desert tortoise, Mohave ground squirrel, and burrowing owl to compensate for project-related loss of habitat. This compensation land is located directly west of the project site and

will provide suitable foraging habitat for golden eagles and other bird species found within the area. Mojave Solar, LLC, will provide funding for the enhancement and long-term management of the compensation lands.

- Compensatory Funding: Mojave Solar, LLC, has provided funding into the Renewable Energy Action Team account established with the National Fish and Wildlife Foundation. This money will fund monitoring and other actions that USFWS, BLM, and the CEC determine to be beneficial to golden eagles located within a 10-mile radius of the MSP.
- Harper Dry Lake Area of Critical Environmental Concern: The MSP ensured continuity of water delivery to the Harper Dry Lake Area of Critical Environmental Concern (ACEC) by providing an alternate well able to effectively convey a minimum of 75 acre-feet per year of water to the Harper Dry Lake marsh. This measure will enhance and provide foraging habitat for birds within the project area.

These four mitigation measures agreed to by Mojave Solar, LLC ensure that potential impacts to golden eagles resulting from project operation will be mitigated.

5.4.2 Common Raven Monitoring, Management, and Control Plan

The *Common Raven, Monitoring, Management and Control Plan* (AECOM, 2010) outlines management actions for the construction site and related facilities to control raven populations. Such actions aim to mitigate cumulative and indirect impacts to desert tortoise associated with regional increase in raven numbers. To address indirect cumulative effects not fully eliminated by the Common Raven Monitoring, Management and Control Plan, Mojave Solar, LLC, paid $105 for each acre of land permanently disturbed by the project. The funds were placed in an account to be administered by the National Fish and Wildlife Foundation to implement measures for managing common ravens.

5.4.3 Evaporation Pond Management/Remediation Plan

An Evaporation Pond Management/Remediation Plan outlines measures to monitor water quality and bird use of the associated project evaporation ponds and adjacent Harper Dry Lake wetland (CEC, 2010). An adaptive framework will specify measures to discourage bird use and the circumstances under which they will be implemented.

5.5 Mitigation Measures

Several mitigation measures are in place as specified by the CEC Decision and its associated management plans (CEC, 2010). Mitigation measures aim to compensate for unavoidable negative impacts incurred by wildlife species as a result of the construction and operation of the MSP. Although some measures result from direct impacts to specific species, the mitigation benefits are construed to extend to other bird and wildlife species. These mitigation measures address both project construction and operations and are discussed in greater detail above:

- Acquisition of compensatory agricultural lands

- Acquisition of compensatory lands to serve as wildlife habitat
- Provide compensatory funding
- Provide an additional water source for Harper Dry Lake ACEC

6.0 Avian Mortality Monitoring and Reporting

COC BIO-17 (see Section 1.1) calls for the project owner to develop and implement a plan to determine the impacts of the MSP on bird species flying in the vicinity of the project site. To this end, this proposed plan presents survey methodologies to determine avian carcass densities.

6.1 Survey Design

An important aspect of this methodology is that MSP proposes to survey for bird carcasses across the entire facility daily, 365 days per year. This 100 percent coverage is made possible because MSP personnel will be conducting daily surveys of the entire facility. The avian component of these surveys will occur for one year (12 months) to determine the daily number and location of dead birds in the solar fields and evaporation ponds. Data will be assessed after one year with the option to implement an adaptive management framework including potential additional years of surveys.

Avian survey design generally follows USFWS recommendations (Nicolai et al., 2011) and has three elements: strata, routes, and analysis.

1. Strata: Conceptually, for this study, the project site is divided into two survey strata according to potential bird mortality hazard types:
   a. Two fields of parabolic trough arrays totaling about 1,765 acres
   b. Four evaporation ponds totaling about 20 acres

   A pre-existing transmission line provides power grid access and, because it is pre-existing, is not included as a stratum for purposes of this study.
2. Routes: Permanently established routes placed across 100 percent of each strata area. For mirror fields, the centerline of each route will be placed in the center of access roads between each mirror row and on perimeter roads. The distance between mirror rows is approximately 60 feet. This will afford observers a clear observation distance of 180 feet (90 feet to either side of route line). Clear observation distance along evaporation ponds is estimated to be 150 feet to either side of a route line. Routes will be surveyed daily, 365 days/year. Routes will not be surveyed during severe weather events (e.g. heavy rain), and will resume the day immediately following the event.
3. Analysis: A spatial and temporal (365 days/year) coverage of 100 percent provides for a complete survey of the strata areas, thereby negating the need to estimate and extrapolate carcass densities. Because surveys occur every 24 hours, scavenger affects will be negligible.

6.2 Route Layout

6.2.1 Solar Trough Array

The centerlines of routes in the solar fields will follow the center of all existing perimeter roads, and access roads between mirror rows—extending their full length. Because all access roads will be surveyed, 100 percent of the solar field will be observed, which exceeds the USFWS recommendations (10% to 30%; Nicolai et al., 2011).

6.2.2 Evaporation Ponds

Routes will follow evaporation pond perimeters and traverse all cardinal directions to account for the effects of wind in the dispersal of animals *post mortem*. Coverage of all perimeters provide for 100 percent coverage, which exceeds the USFWS recommendations (10% to 30%; Nicolai et al., 2011).

6.3 Surveys Along Routes

Routes will be searched by project personnel trained by the Designated Biologist in proper search techniques. Observers will drive routes in an open air vehicle traveling at a maximum of 10 miles per hour (mph) in the solar fields and adjacent to evaporation ponds while scanning away from the route centerline to search for bird carcasses (other animal carcasses will also be logged). For each occurrence, the observers will record date, time, global positioning system (GPS)-determined coordinates of the carcass, and other information on carcass situation (e.g., floating in pond) and condition (e.g., singed feathers). Appendix B provides a sample field data form. Casualties found will be photographed in situ upon initial discovery and reviewed for identification by an offsite, approved designated biologist. All carcasses will be marked, collected and preserved for disposal upon discovery (see section 6.4). The observer will resume the route survey and repeat this procedure for all encountered carcasses. All routes will be completed in a single day and repeated each day throughout the year.

Carcass condition will be assigned to one of the following classes at each encounter:

1. Fresh: eyes are still wet and not completely sunk into sockets
2. Medium: eyes are completely sunk into sockets and breast muscle and viscera still present
3. Desiccated carcass: a stiff carcass consisting of a dried complete carcass
4. Remnant: a dried and reduced carcass consisting of chiefly feather and bone

Additional information will be recorded about the presence or absence of evidence of superheating (singed feathers). To help identify raptor carcasses to species, searchers can use the raptor remains identification guide (CEC, 2005).

6.4 Carcass Disposal

All carcasses will be collected for disposal upon initial discovery. A copy of the field data form completed when the carcass was initially found will be kept with the carcass at all times. An incidental carcass[1] encounter form will be used to document incidental carcasses or injured animals found at the time of collection. A photograph and location information will be provided to the Designated Biologist. Species and cause of death will be determined (if possible) and a record maintained in a database. All carcasses will be labeled and retained or disposed of following guidance from CDFW and/or USFWS.

Injured native birds may be captured and transported by trained personnel to a designated rehabilitation center or veterinary clinic. Guidance for handling injured birds is provided in Appendix C. All appropriate collection permits will be obtained from USFWS and/or CDFW for handling and collecting protected species.

6.5 Analysis

The Designated Biologist, or agency-approved personnel, will maintain a database of survey information. Because strata are surveyed at 100 percent coverage, all dead birds are expected to be found on a daily basis. Observer error and carcasses scavenging should be minimal and fall within acceptable calculated error rates expected from a study design that uses a sampling and estimation approach. When a full year’s bird mortality survey is obtained, consideration will be made by the CEC and USFWS for the need to continue monitoring or protocol refinement.

6.6 Reporting

Reports will be submitted at least quarterly detailing survey results and all other project-related bird mortalities. The Designated Biologist will prepare annual reports detailing the monitoring results and project-related bird mortalities and make recommendations for adaptive management actions needed. Reports will be submitted to the CPM, CDFW, and USFWS and will continue as long as surveys occur. Surveys will occur for a minimum of one year and may continue longer as determined by the CEC and USFWS. At the conclusion of the study, the project owner or contractor will prepare a manuscript to be submitted to a peer-reviewed scientific journal.

6.7 Adaptive Management

Adaptive management is a means to address unforeseen conditions on the project site that affect wildlife through direct injury or mortality. The death or injury of wildlife from project operation is currently an unforeseen condition. Adaptive management measures will be developed to avoid or minimize bird injuries/deaths should project-related mortalities occur. The CPM, in consultation with CDFW and USFWS, will determine when and/or if the implementation of adaptive measures is warranted.

---

[1] An incidental carcass is any carcass found while not conducting carcass survey

Current measures are already in place to minimize project-related impacts to birds (USFWS Determination on Golden Eagle Territory-Specific Management Plan, Common Raven Monitoring and Control Plan Mojave Solar Project) (Abengoa Solar, 2011; AECOM, 2010; 2011b). If new measures are required, they would be based on the actual effect of the MSP on avian species and may include measures developed in consultation with individuals knowledgeable about the species of concern. At a minimum, measures will be developed in consultation with the CPM, the Designated Biologist, USFWS, CDFW, and the project owner's design team.

At this time, adaptive measures cannot be developed without knowledge of the project-related impacts that result in deaths or injuries to the species of concern. However, should they be necessary, future adaptive measures may include, but are not limited to the following:

- Installation of bird deterrents (e.g., artificial scarecrows)
- Modification of lighting that may attract insects (potential avian forage)
- Installation of noise deterrents such as predator calls or bird alarms, propane cannons, or high-frequency emitters

The Designated Biologist will implement and monitor any adaptive measures, and determine their effectiveness in consultation with the CPM, CDFW, and USFWS.

Appendix C
Injured Wildlife Procedures for Reporting and Care

Mojave Solar Project
Injured Wildlife Procedures for Reporting and Care

The following procedures apply to injured birds or other wildlife. Record data on an Incidental Carcass Encounter Form. However, the primary objective is to provide immediate care for the injured animal. Project personnel trained by the Designated Biologist may capture the animal by placing a dark cloth or blanket over it. By removing its ability to see, generally it will calm down and be more easily handled. Place the animal in a box that has a towel or other material for the animal to hide under or grasp on to. Personnel will use protective gloves and clothing when handling wildlife.

Quickly look around the immediate area for other injured animals as there may have been a flock or a pair. While capturing the animal, the biological monitor should assess the injury so he or she will know what to report to the wildlife rehabilitator or veterinarian. Do not provide additional stress. Keep the injured animal cool if it is a hot day and keep it slightly warm if it is a cool day by placing the box indoors in a darkened room if possible.

If it is a federally listed (Threatened, Endangered) or California State listed (Threatened, Endangered) species, the Designated Biologist or Environmental Manager will contact the appropriate agency.

- The contact information for CDFW Region 6 (Imperial, Inyo, Mono, Riverside, and San Bernardino Counties) is: 3602 Inland Empire Boulevard, Suite C220, Ontario, CA 91764 (telephone: (909) 484-0167; website: http://www.dfg.ca.gov/regions/6/).
- For federally listed species, the Environmental Manager or Designated Biologist should contact USFWS at: 2493 Portola Road, Suite B, Ventura, CA 93003 (telephone: (805) 644-1766; website: http://www.fws.gov/ventura/).

These calls should be made within 24 hours of discovery. Telephone the designated rehabilitation center (to be determined) for additional instructions. Describe the injury to the rehabilitation center and they will determine if it should go directly to a veterinary clinic.

Deliver the animal to the specified location as directed by the regulatory agencies or the clinic. The veterinarian should fill out the “Casualty Examination Form.” The clinic will make arrangements to deliver the animal to the designated rehabilitation center. MSP will pay for all veterinary bills.

Prepared on:

April 10, 2014

REPORTING PERIOD: February 3 through February 10, 2014

REPORT: Avian Mortality Monitoring Report #4

This report summarizes the Avian Mortality Surveys conducted by UltraSystems biological staff at the Imperial Solar Energy Center (ISEC) South facility (private land). This is the fourth post-construction avian mortality monthly report for the ISEC South facility, and is prepared in accordance with the Avian and Bat Protection Plan, Imperial Solar Energy Center South (CH2MHill 2011) and conditions of the U.S. Fish and Wildlife Service–Pacific Southwest Region Monitoring Migratory Bird Take at Solar Power Facilities: An Experimental Approach (Nicolai, et al. 2011). Survey data sheets are included in **Appendix A**.

SURVEY METHODOLOGY

During the month of February 2014, avian mortality surveys were conducted in the solar panel fields and along the power collection system. These surveys were conducted in accordance with the methods described by the U.S. Fish and Wildlife Service (Nicolai, et al.), with the following modification: surveys were conducted by two observers in a vehicle traveling at a rate that did not exceed three miles per hour (approximately walking speed).

A systematic search pattern was selected using transects within the solar panel fields, as there are existing access roads that run north to south between the solar panels. There were 25 north-south transects used, as illustrated in **Figure 1**. In order for the survey area to be representative of the entire project site, either odd or even-numbered transect lines were selected at random. This insured that no part of the project area would be over or under-represented. A coin toss decided upon odd-numbered transect lines (see **Figure 2**). These transects are 1, 3, 5, 7, 11, 13, 17, 19, 21, 23, 27, 29 and 31. The entire power collection system line was surveyed, as well.

The Avian and Bat Protection Plan states to survey 10% of the solar facility. The ISEC South solar facility has a total of 946.6 acres. The odd transects that were selected account for 95 acres of the facility based on a 30-foot line of sight while driving the transect lines. Therefore, the 10% coverage requirement for these surveys is met, and not all transects need to be selected.

While driving these north-south transects, observers surveyed west and east down each solar panel row, viewing a minimum of 13 feet on each side of the vehicle. The average total width of each transect was a minimum of 95 feet. If a possible avian mortality was spotted, observers would verify the find using binoculars. Mortalities were recorded on two data forms; one for the solar panel field and the other for the power collection system line (see **Appendix 1**). The survey period was conducted for seven consecutive days, and at least 10% of the solar field was surveyed. Surveys were conducted beginning at 8 a.m. and were completed by 2 p.m. Surveys were only conducted on days with no rain or fog, and on days where wind velocities did not exceed 20 miles per hour.

Data Collection Methods

Observers drove the transect lines in pairs (not exceeding three miles per hour), with each observer looking between solar panels along each respective row.

At each detection of an avian carcass the following information was recorded:

- Transect Number
- Unique carcass I.D.

Colored embroidery thread or similar material was used to uniquely identify each carcass. The embroidery thread was attached to legs as part of a unique identification, and the following information was recorded in the carcass I.D.

- Leg: L = Left; R = Right
- Color of thread: TN=Tan, GN=Green, BN=Brown, BK=Black, BE=Blue, CR=Copper
- Knots in the thread (number of birds of that specific species found, for that survey): 0=1, 1=2, 2=3, 3=4, 4=5, etc.

As an example, the code LCR00 indicates that the thread was attached to the left foot, the species code indicated by using the copper color thread, and there were no knots, meaning this was the first bird of that specific species found during the survey.

Additional information recorded includes:

- Panel strike Y/N or Line strike Y/N.
- Species (American Ornithologists' Union (AOU) 4-letter species code).
- Carcass Condition:
    - Fresh (eyes are still wet and not totally sunk into sockets)
    - Medium (eyes are totally sunk into sockets and breast muscle and viscera still present)
    - Non-scavenged carcass (a stiff carcass consisting of a dried complete carcass)
    - Remnant (a dried carcass consisting of non-edible parts)
- GPS Coordinates (NAD 83 Decimal Degrees).
- Cause of death will be determined and recorded if possible, otherwise it will be recorded as unknown. Examples of evidence that could help determine cause of death include: marks on panel where the bird struck, or bird directly below a line, etc.
- Vegetation percent and height estimate.
- Presence or absence of evidence of superheating (singed feathers).

Carcasses, if discovered, were to be left exactly as found.

James Castle (Senior Wildlife Biologist), Patrick Hord and Renee Owens (UltraSystems Biologists) conducted the surveys during February 2014.

AVIAN MORTALITIES DISCOVERED BY ULTRASYSTEMS

Table 1

Date	Transect Number	Unique Number	Species	GPS Coordinates (NAD 1983)
2/3/14	3	None	MODO[1,2]	32.65507°, –115.66932°
2/6/14	5	None	MODO[3]	32.66288°, –115.66788°

1. MODO is the four-letter bird species code for Mourning Dove.
2. This MODO was mostly feathers with some bone and bone fragments.
3. This MODO was mostly feathers with some bone and bone fragments.

1. CAEG is the four-letter bird species code for Cattle Egret.
2. This CAEG was mostly head and feathers.

OTHER WILDLIFE

An injured juvenile Sora (SORA) was recovered in Block 3 on 2/9/2014. This bird was captured and transported to the Wild Bird Center in Coachella Valley, California. The SORA was alert and appeared to have an injury to the left eye and a small amount of blood on the beak. A follow-up concerning the condition of the bird will be made by UltraSystems Biologists.

AVIAN FATALITY MONITORING FORM

Directions: This form is to be completed per the obligations set in the ISEC South Avian and Bat Protection Plan, Section 6.1. The form should be completed when a fatality is sighted on the project site or adjacent properties. Each fatality observation made for the day should be reported on a separate form. At the end of each site visit day, forms should be submitted to CSolar IV South, LLC.

Project Name: Imperial Solar Energy Center South

Date (mm/dd/yyyy): 2/17/2014

Name of Monitor: Kris Halford

Start Time: 7am ☒ AM ☐ PM

End Time: 14:00 ☐ AM ☒ PM

GENERAL LOCATION

City: Calexico

County: Imperial

Township/Range/Section: T: 17S, R: 13E, Sec: 17, 20, & 21

1. SPECIES INFORMATION

Common Name: Cattle Egret

Condition of Bird? ☑ Dead ☐ Injured

Cause of Death/Injury: ☐ Panel Strike ☐ Linel Strike ☐ Electrocution ☑ Other

Is the species a Raptor*? ☐ Yes ☒ No

*Raptors are birds of prey - i.e. Hawks, Eagles, Falcons, Owls are characterized by large talons and hooked bills

****Raptor fatalities must be reported to CSolar immediately****
Contact: Mary Zgoda at 402-938-1662 (office) or 402-203-2357 (cell)

Evidence/Description of Injury:

Unable to tell what caused death, partially consumed by preditor

2. LOCATION OF FATALITY

Location Description (i.e. Block, Access Road, etc.): See below

Block 2 By PCS 3 and 6

GPS Location

Latitude (Decimal Degrees; e.g. 32.56832): N/A

Longitude (Decimal Degrees; e.g. -115.45448): N/A

GPS coordinate system to be used: WGS 84 N/A

Action Taken (Do Not Remove Bird): Took photos and left bird in place

COMMENTS
Include weather or other pertinent information

clear day - no storms in days previous

UPS CampusShip: View/Print Label

1. **Ensure there are no other shipping or tracking labels attached to your package.** Select the Print button on the print dialog box that appears. Note: If your browser does not support this function select Print from the File menu to print the label.

2. **Fold the printed sheet containing the label at the line so that the entire shipping label is visible. Place the label on a single side of the package and cover it completely with clear plastic shipping tape. Do not cover any seams or closures on the package with the label.** Place the label in a UPS Shipping Pouch. If you do not have a pouch, affix the folded label using clear plastic shipping tape over the entire label.

3. **GETTING YOUR SHIPMENT TO UPS**
   UPS locations include the UPS Store®, UPS drop boxes, UPS customer centers, authorized retail outlets and UPS drivers.
   Schedule a same day or future day Pickup to have a UPS driver pickup all your CampusShip packages.
   Hand the package to any UPS driver in your area.
   Take your package to any location of The UPS Store®, UPS Drop Box, UPS Customer Center, UPS Alliances (Office Depot® or Staples®) or Authorized Shipping Outlet near you. Items sent via UPS Return Services(SM) (including via Ground) are also accepted at Drop Boxes. To find the location nearest you, please visit the Resources area of CampusShip and select UPS Locations.

   Customers with a Daily Pickup
   Your driver will pickup your shipment(s) as usual.

REPORTING PERIOD: March 3, 2014 through March 9, 2014

REPORT: Avian Mortality Monitoring Report #5

This report summarizes the Avian Mortality Surveys conducted by UltraSystems biological staff at the Imperial Solar Energy Center (ISEC) South facility (private land). This is the fifth post-construction avian mortality monthly report for the ISEC South facility, and is prepared in accordance with the Avian and Bat Protection Plan, Imperial Solar Energy Center South (CH2MHill 2011) and conditions of the U.S. Fish and Wildlife Service–Pacific Southwest Region Monitoring Migratory Bird Take at Solar Power Facilities: An Experimental Approach (Nicolai, et al. 2011). Survey data sheets are included in **Appendix A.**

SURVEY METHODOLOGY

During the month of March 2014, avian mortality surveys were conducted in the solar panel fields and along the power collection system. These surveys were conducted in accordance with the methods described by the U.S. Fish and Wildlife Service (Nicolai, et al.), with the following modification: surveys were conducted by two observers in a vehicle traveling at a rate that did not exceed three miles per hour (approximately walking speed).

A systematic search pattern was selected using transects within the solar panel fields, as there are existing access roads that run north to south between the solar panels. There were 25 north-south transects used, as illustrated in **Figure 1.** In order for the survey area to be representative of the entire project site, either odd or even-numbered transect lines were selected at random. This insured that no part of the project area would be over or under-represented. A coin toss decided upon odd-numbered transect lines (see **Figure 2**). These transects are 1, 3, 5, 7, 11, 13, 17, 19, 21, 23, 27, 29 and 31. The entire power collection system line was surveyed, as well.

The Avian and Bat Protection Plan states to survey 10% of the solar facility. The ISEC South solar facility has a total of 946.6 acres. The odd transects that were selected account for 95 acres of the facility based on a 30-foot line of sight while driving the transect lines. Therefore, the 10% coverage requirement for these surveys is met, and not all transects need to be selected.

While driving these north-south transects, observers surveyed west and east down each solar panel row, viewing a minimum of 13 feet on each side of the vehicle. The average total width of each transect was a minimum of 95 feet. If a possible avian mortality was spotted, observers would verify the find using binoculars. Mortalities were recorded on two data forms; one for the solar panel field and the other for the power collection system line (see Appendix 1). The survey period was conducted for seven consecutive days, and at least 10% of the solar field was surveyed. Surveys were conducted beginning at 8 a.m. and were completed by 2 p.m. Surveys were only conducted on days with no rain or fog, and on days where wind velocities did not exceed 20 miles per hour.

Post-Construction
Avian Mortalities - March 2014

UltraSystems

Data Collection Methods

Observers drove the transect lines in pairs (not exceeding three miles per hour), with each observer looking between solar panels along each respective row.

At each detection of an avian carcass the following information was recorded:

- Transect Number
- Unique carcass I.D.

Colored embroidery thread or similar material was used to uniquely identify each carcass. The embroidery thread was attached to legs as part of a unique identification, and the following information was recorded in the carcass I.D.

- Leg: L = Left; R = Right
- Color of thread: TN=Tan, GN=Green, BN=Brown, BK=Black, BE=Blue, CR=Copper
- Knots in the thread (number of birds of that specific species found, for that survey): 0=1, 1=2, 2=3, 3=4, 4=5, etc.

As an example, the code LCR00 indicates that the thread was attached to the left foot, the species code indicated by using the copper color thread, and there were no knots, meaning this was the first bird of that specific species found during the survey.

Additional information recorded includes:

- Panel strike Y/N or Line strike Y/N.
- Species (American Ornithologists' Union (AOU) 4-letter species code).
- Carcass Condition:
    1. Fresh (eyes are still wet and not totally sunk into sockets)
    2. Medium (eyes are totally sunk into sockets and breast muscle and viscera still present)
    3. Non-scavenged carcass (a stiff carcass consisting of a dried complete carcass)
    4. Remnant (a dried carcass consisting of non-edible parts)
- GPS Coordinates (NAD 83 Decimal Degrees).
- Cause of death will be determined and recorded if possible, otherwise it will be recorded as unknown. Examples of evidence that could help determine cause of death include: marks on panel where the bird struck, or bird directly below a line, etc.
- Vegetation percent and height estimate.
- Presence or absence of evidence of superheating (singed feathers).

Carcasses, if discovered, were to be left exactly as found.

James Castle (UltraSystems Senior Wildlife Biologist), Charlene Burge, Mike Robinson and Gabriella Machal (UltraSystems Biologists) conducted the surveys during March 2014.

AVIAN MORTALITIES DISCOVERED BY ULTRASYSTEMS

There were two avian mortalities discovered by UltraSystems biologists during the March 2014 survey.

Table 1

Date	Transect Number	Unique Number	Species	GPS Coordinates (NAD 1983)
3/3/14	3	LGN00	SORA[1]	32.66246°, -115.67128°
3/3/14	29	LCR01	SORA	32.67078°, -115.65972°

1. SORA is the four-letter bird species code for Sora.

AVIAN MORTALITIES DISCOVERED BY FACILITY PERSONNEL

There were no avian mortalities discovered by facility personnel during the March 2014 reporting period.

UPS CampusShip: View/Print Label

1. **Ensure there are no other shipping or tracking labels attached to your package.** Select the Print button on the print dialog box that appears. Note: If your browser does not support this function select Print from the File menu to print the label.

2. **Fold the printed sheet containing the label at the line so that the entire shipping label is visible. Place the label on a single side of the package and cover it completely with clear plastic shipping tape. Do not cover any seams or closures on the package with the label.** Place the label in a UPS Shipping Pouch. If you do not have a pouch, affix the folded label using clear plastic shipping tape over the entire label.

3. **GETTING YOUR SHIPMENT TO UPS**
   UPS locations include the UPS Store®, UPS drop boxes, UPS customer centers, authorized retail outlets and UPS drivers.
   Schedule a same day or future day Pickup to have a UPS driver pickup all your CampusShip packages.
   Hand the package to any UPS driver in your area.
   Take your package to any location of The UPS Store®, UPS Drop Box, UPS Customer Center, UPS Alliances (Office Depot® or Staples®) or Authorized Shipping Outlet near you. Items sent via UPS Return Services(SM) (including via Ground) are also accepted at Drop Boxes. To find the location nearest you, please visit the Resources area of CampusShip and select UPS Locations.

   Customers with a Daily Pickup
   Your driver will pickup your shipment(s) as usual.

UPS CampusShip: View/Print Label

1. **Ensure there are no other shipping or tracking labels attached to your package.** Select the Print button on the print dialog box that appears. Note: If your browser does not support this function select Print from the File menu to print the label.

2. **Fold the printed sheet containing the label at the line so that the entire shipping label is visible. Place the label on a single side of the package and cover it completely with clear plastic shipping tape. Do not cover any seams or closures on the package with the label.** Place the label in a UPS Shipping Pouch. If you do not have a pouch, affix the folded label using clear plastic shipping tape over the entire label.

3. **GETTING YOUR SHIPMENT TO UPS**
UPS locations include the UPS Store®, UPS drop boxes, UPS customer centers, authorized retail outlets and UPS drivers.
Schedule a same day or future day Pickup to have a UPS driver pickup all your CampusShip packages.
Hand the package to any UPS driver in your area.
Take your package to any location of The UPS Store®, UPS Drop Box, UPS Customer Center, UPS Alliances (Office Depot® or Staples®) or Authorized Shipping Outlet near you. Items sent via UPS Return Services(SM) (including via Ground) are also accepted at Drop Boxes. To find the location nearest you, please visit the Resources area of CampusShip and select UPS Locations.

Customers with a Daily Pickup
Your driver will pickup your shipment(s) as usual.

Avian and Wildlife Reporting Form

***** All Fields Must Be Filled Out. Do Not Leave Any Field Blank. *****

INCIDENT DETAILS

Observation Made During (circle one):

Evaporation Pond Monitoring / Scheduled Mortality Survey / [✓ Incidental]

Date: 6/10/2013 Observer: Ron Walker

Type of Incident (circle one): [✓ Injury] / Fatality / Nest

Condition (circle one): Intact Carcass / Dismembered Carcass / Feathers Only

Age of Remains (circle one): 1-5 (fluid filled eyes) / 6-30 (maggots) / 30+ (bones)

Photo No. ____________________

Carcass Condition Details, Behavior of Injured Animal or Nest Details: Injured brown pelican found in unit 2 in power block area under HTF overhead pipes, above power block access road. Pelican appeared to be suffering from heat stress. Pelican transported to wildlife rehabilitation center in Blythe, CA. It was reported later that the pelican recovered and was released uninjured.

LOCATION

DATUM: UTM Z11 NAD83 (m) UTM N: 3726434 UTM E: 686893

Found Near (circle one):

Solar Trough / Evaporation Pond / Road / Power Line / [✓ Other (explain below)]

Location Details: Unit 2, west side of power block, under HTF pipe overhead crossing

IDENTIFICATION

[✓ Bird] / Bat / Unknown / Other (circle one)

Species (if unknown, write 'unknown'): Brown Pelican

Color/Markings: Brown, light underbelly

Sex (circle one): Male / Female / [✓ Unknown] Age (circle one): Adult / Juvenile / [✓ Unknown]

Is Animal Tagged? (circle one): Yes / [✓ No]

Identification Remarks: N/A

ENVIRONMENTAL CONDITION

Weather (circle one): [✓ Clear] / Fog / Cloudy / Rain

Approx. Temperature (circle one): [✓ °F] / °C: 109

Wind (circle one): Calm / [✓ Gusty] / Storm / Violent Storm

Habitat (circle all that apply):

Bare Ground / Creosote Bush Scrub / Sand Dunes

Sand Drifts over Playa / Ephemeral Wash / Desert Pavement

NOTIFICATION

Who was notified, and When? Designated biologist on 6/10/2013 4:30:00 PM

Actions Taken (e.g., left in place, taken to rehab): Brown pelican picked up and transported to wildlife rehabilitation center in Blythe CA

COMMENTS:

Injured brown pelican found in unit 2 in power block area under HTF overhead pipes, above power block access road. Pelican appeared to be suffering from heat stress. Pelican transported to wildlife rehabilitation center in Blythe, CA. It was reported later that the pelican recovered and was released uninjured.

* Turn in completed form and incident photos to the on-site Environmental Manager.

* Report any incidental observations of dead birds or other wildlife at the evaporation ponds to the Designated Biologist within one day of the detection of the carcass.

* Report any nests immediately to the on-site Environmental Manager.

County of San Bernardino
Office of the District Attorney
MICHAEL A. RAMOS, District Attorney

September 16, 2015

NRG Energy
100 California Street
Suite 650
San Francisco, CA 94111

Attention: John Chillemi

Dear Mr. Chillemi,

A case has been submitted to this office for review and filing consideration concerning alleged violations of the California Fish & Game Code at the Ivanpah solar plant. Prior to any filing decision, we would like to discuss the issues involved and this letter is sent with the intent to open that dialogue. We are interested in learning more about the program(s) that have been put in place to mitigate any harm to wildlife on or around the Ivanpah facility.

Please call or email at your earliest convenience and thank you for your attention to this matter,

Douglas Poston
Lead Deputy District Attorney
San Bernardino County
Consumer & Environmental Protection Unit

Wildlife Mortality Report
Imperial Solar Energy Center West

To: Nicollee Gaddis (BLM), Magdalena Rodriguez (CDFW), Pete Sorenson (USFWS), Jody Fraser (USFWS), Tom Dietsch (USFWS) and David Black (Imperial County)

From: Michael Robinson, Lead Designated Biologist (UltraSystems)

Date: 02-23-2015

Re: Burrowing Owl Mortality – Imperial Solar Energy Center (ISEC) West

---

Occurrence:

On February 23, 2015 at 2:30 p.m., Fern Hoffman (UltraSystems biologist) found the remains of a burrowing owl (BUOW) (*Athene cunicularia*) during transect surveys on the ISECW project on private land. The BUOW is a Bureau of Land Management (BLM) Sensitive Species and a California Species of Special Concern.

Ms. Hoffman found a feather spot that consisted of both body and flight feathers. The spot diameter was over 15 feet due to wind scatter though the primary feather spot was about 1 foot by 2 feet. The BUOW appeared to have been scavenged; however, the cause of death was indeterminate. The weathering on the feathers led Ms. Hoffman to conclude that the feathers were more than two weeks old, but less than a month. The feathers were found near a rodent complex and were about 20 feet away from a suitable BUOW burrow. Weather conditions at the time of discovery were sunny with scattered clouds, 70 degrees Fahrenheit, with winds at 4 to 13 miles per hour.

The BUOW feathers and location were photographed (see Attachment A), and information regarding the occurrence was recorded. While there was no carcass found, the amount of body and flight feathers determine it was one adult BUOW.

GPS Location: this BUOW was found at GPS coordinates 32.76315, -115.78596.

Should you have any questions, please contact me at (949) 939-8814.

Sincerely,

Michael Robinson

Michael Robinson, Lead Designated Biologist

Genesis Solar Avian Injury and Mortality Response

Meeting Notes

July 22, 2013

Attendees

- NextEra/Genesis
  - Jennifer Field – Permitting and Compliance
  - Janine Bacquie – Wildlife Permitting
  - Bill Watson – Genesis Director of Compliance
- AECOM
  - Jennifer Guigliano – Biology Compliance PM
  - Eric German – Designated Biologist
- USFWS
  - Erin Dean – USFWS Resident Agent (Law Enforcement)
  - Edwardo Nieves – CDFW Special Agent (Law Enforcement)
  - Tom Dietsch – Migratory Birds, Carlsbad
  - Tera Baird – Project Biologist
- CDFW
  - Magdalena Rodriguez – Project Biologist

1. <u>Current process</u>: Calling biologists to report the mortalities, not handling, and getting direction via email from either CDFW/USFWS
2. USFWS appreciates efforts to date to share information and coordinate
3. Letter was going to be issued from law enforcement; however no longer doing a letter. Now expecting to issue a short term SPUT (good for 6 months) which is based upon the current APP and will identify how to handle mortalities, injuries, etc.
   a. Fill out normal SPUT application and send to the Attention of Heather Beeler; cc to Tom Dietsch
4. Following the temporary SPUT, a permanent SPUT will be issued that would be effective for the operational life of the project (USFWS to confirm this is for life of project or just 3 years as is typical of SPUT permits) and would be based upon a new BBCP…which will actually be an amendment to the current APP through the CEC.
5. Erin Dean, Law Enforcement questioned how we proceed until temp SPUT issued. From today on, Edwardo Nieves will be contacted for any mortality or injury and Ed will provide verbal instruction. Ed will provide written follow-up after the verbal is issued (via email).
6. Tom indicated processing the SPUT permit would only be a couple weeks. Until then, we will continue to call Edwardo.
7. Tom/USFWS is updating a spreadsheet for mortality monitoring. Should be able to update our tracking system with the requested information by updating fields. Tom will provide that information before SPUT is issued to so that we can modify our database as necessary.
8. Freezer has been ordered, should be onsite by approximately 2 weeks. Note - Freezer needs to have a lock to prevent access to evidence

9. Ed has requested to come out to provide training to Eric and Ron on the collection and logging of bird mortalities.
10. SPUTs (temporary and permanent) will cover NexEra, Genesis, and any persons employed by or contracted by NextEra. Tom to clarify this language/coverage as well as the term length for the permit (3 year renewal period).
11. AECOM will continue to use our current data processing and collection system for avian injuries and mortalities and summarizing them in a tabular format. The spreadsheet as well as backup forms are provided in the MCRs and will continue to be. Tom asked for the data to be submitted separately on a monthly basis to the USFWS. AECOM to send the spreadsheet to USFWS monthly (send to Tera and Tom).
12. Magdalena discussed the use of SCPs for avian species. Without a State SCP with salvage permit…cannot collect at all. CDFW concern about directing “takings” of protecting fully protected species and strigiformes/falconiformes. Federal law enforcement stated that there is no issue with state if they are directed by federal law enforcement. As long as law enforcement is contacted directly, take issue is covered…including T&E (federally).
13. Magdalena circling with Regional Manager and Law Enforcement with CDFW (Lt. King), mainly with listed species or fully protected. Wants to verify the direction. Erin Dean (USFWS) knows Lt. King and will follow up with him as well.
14. Magdalena will talk to Blythe to see if we can continue to have them collect birds and put in freezer.
15. May use coolers and ice. Is a chain of custody protocol for bird collection and will be trained by Ed N.

ACTION ITEMS

- ☐ Prepare application for temporary SPUT. Submit with fees.
- ☐ Freezer is being acquired for Genesis site.
- ☐ Do not handle birds. Contact Ed, USFWS Law Enforcement for verbal and written direction. Birds will be managed following receipt/confirmation via written form.

  310-328-1516 (Office)
  310-612-4744 (Cell)
  eduardo_nieves@fws.gov

- ☐ Ed to train Eric and Ron regarding collection and logging for bird mortalities (and injuries) .
- ☐ USFWS, CDFW to confirm with law enforcement both sides that no separate state permits, letters, or direction is necessary to proceed with bird injury/mortality reporting/collection.
- ☐ Submit the avian injury/mortality reporting summary table separately to Tera and Tom when MCR is submitted to CEC.
- ☐ Tom to provide updated data collection information to facilitate update to AECOM data collection.
- ☐ Revision to APP coordinated through CEC with USFWS and CDFW.
- ☐ Long-term SPUT to be applied for and issued following concurrence on final APP amendment.

Section 1. Introduction

Through adoption of Resolution #2011-119, the Board of Supervisors of the County of San Luis Obispo (County) approved the California Valley Solar Ranch Project (CVSR Project) Conditional Use Permit (DRC2008-00097) on 19 April 2011. The Conditional Use Permit is subject to the Conditions of Approval (COAs) set forth in Exhibit 6 attached to the Resolution.

The Conditional Use Permit allows the Applicant (High Plains Ranch II, LLC, and any successor in interest for the life of the CVSR Project) to construct and operate a 250-megawatt (MW) photovoltaic solar power plant on an approximately 4685 acre (ac) site, located mostly south of State Route (SR) 58, about 4 miles east of Soda Lake Road, immediately north of the California Valley subdivision, in the Shandon-Carrizo planning area in San Luis Obispo County (CVSR site).

COA #58 of the CVSR Project Conditional Use Permit requires an Avian Fatality Monitoring Plan (Plan) for the CVSR Project and a quarterly report detailing any project-related bird deaths or injuries detected during the monitoring study or at any other time. To satisfy COA #58 of the CVSR Project Conditional Use Permit, the Applicant has prepared this *Avian Fatality Quarterly Report,* which documents the number of avian mortalities detected during project construction from January through March 2013. Results of studies detailed in the Plan for post-construction monitoring in operational portions of the Project site are covered in separate *Avian Fatality Quarterly Reports* timed to coincide with seasonal patterns of avian occurrence on the site. The first of these Plan reports covered the period from 16 August – 15 November 2012.

Section 2. Monitoring Methodology

Per COA #58, the Plan requires monitoring the death and injury of birds associated with facility features such as feeder/distribution lines, solar panels, fences, and evaporation ponds. This Report documents avian mortality detected during construction activities from January through March 2013.

Monitoring of avian mortalities occurred during standard pre-activity surveys and construction monitoring 6–7 days per week throughout the quarter. Avian mortality data is collected within daily construction monitoring data sheets and includes date, location, and details of each observation.

Section 3. Results

From January through March 2013, 4 on-site avian fatalities were observed during construction monitoring (Table 1). Cause of death for all 4 avian fatalities is unknown.

Table 1. Avian Fatalities Detected during Construction-related Activities from January through March 2013.

Date	Species	No.	Location	Observation Details
1/17/13	House finch (*Carpodacus mexicanus*)	1	MVOH Segment 4B UTM: 11S 0234700 3913059	Found dead on a giant kangaroo rat precinct underneath power lines at 2:00 PM.
3/11/13	Mourning dove (*Zenaida macroura*)	1	Western Array 7 UTM 11S 0237568 3911433	Pile of feathers found under panels in western array at 10:30 AM.
3/13/13	Common raven (*Corvus corax*)	1	Ruskovich Well UTM: 10S 0772133 3912664	Found dead with no external injuries under a private transmission line just east of the fence along the east side of the houses at the Ruskovich property at 3:00 PM.
3/16/13	House finch	1	Array 2 UTM: 11S 0234322 3914513	Notified by a construction worker of a dead/dying bird at Production Well-3 at 10:30 AM. Biologist found the bird deceased, with no external injuries, lying on the ground next to a reflective, silver-colored box adjacent to the well, ~10 ft from solar panels. Workers observed bird hopping around the well, sometimes taking short flights, earlier in the morning, but did not see it fly into any panels, equipment, or the well. They reported that it walked to the area next to the silver box where it looked sickly and later died.

Post-Construction Monitoring at the Genesis Solar Energy Project Riverside County, California

2015 Summer Quarterly Interim Report

February 2, 2016

EXECUTIVE SUMMARY

Avian and bat monitoring surveys were conducted from June 01 to August 30, 2015 (the summer season; for logistical reasons, fall monitoring started on Monday, August 31, 2015) at Genesis Solar Energy Project (Project) in accordance with the Project's Bird and Bat Conservation Strategy (BBCS). Specifically, standardized carcass searches, searcher efficiency trials, and carcass persistence trials were conducted. This report represents the second seasonal report for the first year of monitoring, and summarizes monitoring methods and results for those surveys based on the procedures and requirements specified in the BBCS. This report and the other interim quarterly reports are considered preliminary summaries of data and information for the seasonal monitoring periods. Final information from all four quarterly monitoring periods will be included in a comprehensive final annual report.

Standardized carcass searches were conducted 1) in the solar field, consisting of a random stratified 30% sample of solar troughs of both Project units, 2) at each evaporation pond, 3) along the perimeter of each power block and beneath each air condensed cooling (ACC) unit, 4) along inner and outer portions of the "fenceline", resulting in 100% of the length of the perimeter fence surveyed, and 5) along 25% of the total length of generation-tie (gen-tie) and distribution lines (collectively, overhead lines) from the southernmost Project fence to Wiley's Well reststop, which co-occur with the Project access road. Searches were conducted within the summer season at intervals of approximately 21 days, and all components were searched four times. All searches took place during daylight hours from approximately 06:30 to 17:00.

All bird and bat fatalities and injuries that were discovered by observers, referred to as "detections" in this report, including those found incidentally and during standardized carcass searches, were documented. During the reporting period, 55 avian detections and five bat detections were made.

According to specifications of the BBCS, avian detections were categorized by likely diurnal or nocturnal migration behavior, ecological guild (e.g., raptors, songbirds, etc.), facility component, and suspected cause of death. These standardized carcass search results, along with searcher efficiency and carcass persistence rates from bias trials conducted on site, were input into a fatality estimator model (Huso 2010) to provide a preliminary estimate of the number of fatalities that occurred at the Project during the reporting period adjusted for sources of bias. The estimate is considered preliminary because the annual report may pool information from bias trials and other data across seasons which could affect seasonal estimates.

Carcass persistence was influenced by Project component, carcass size, and, in the solar field (solar collector assemblies + perimeter fence), season. In the solar field, small carcasses (0-100 g) had a 52% (90% confidence interval [CI]: 45 – 64%) chance of persisting through the 21-day search interval, medium carcasses (101 – 999 g) had an 92% (90% CI: 76 – 96%) chance, and large carcasses (1000+ g) had a 100% chance. Mean (median) removal time in the solar field was 8.0 (9.0) and 35.1 (30.0) days for small and medium carcasses, respectively. Mean and median removal times for large carcasses in the solar field were not estimated because no removal of large carcasses was observed. Along overhead lines, small carcasses had a 14% (90% CI: 9 – 20%) chance of persisting through the 21-day search interval, medium carcasses had a 59% (90% CI: 42 – 74%) chance, and large carcasses had a 41% (90% CI: 26 – 58%) chance. Mean (median) removal time along overhead lines for small, medium, and large carcasses was 0.8 (0.5), 12.8 (30.0), and 4.6 (3.5) days, respectively. The difference in carcass removal times between Project components is because scavengers likely occur in higher densities outside the perimeter fence.

In the solar field, searcher efficiency averaged over all observers was 92% (86 – 98%) and there was no effect of carcass size, visibility class, or season (n =). Along overhead lines, searcher efficiency averaged over all observers was influenced by carcass size: 54% (90% CI: 39 – 68%) for small birds, 100% for medium birds, and 100% for large birds (n =).

Composition of summer detections included species from 13 avian guilds. No single guild comprised a large number of detections: the most common was blackbirds/orioles (eight detections). Shorebirds and waterbirds/waterfowl were represented by six and seven detections, respectively. Summer was the first season in which bats were detected.

Using the Huso (2010) fatality estimator model, during the summer period 2015, there were an estimated total 100 carcasses (90% CI: 81 - 145) at the Project. Of these, 53 carcasses (53%) were estimated for the SCAs, 8 carcasses (8%) were estimated for the fence, 9 carcasses (9%) were estimated for evaporation ponds, 23 carcasses (23%) were estimated for power blocks, and 7 carcasses (7%; 90% CI: 6 - 21) were estimated for the overhead lines and project road. An estimated 93 (93% CI: 66 - 126) carcasses (50/1000 acres, 0.37/nameplate MW) occurred for all components associated with both solar units (SCAs, power block, evaporation ponds, and along the perimeter fence, combined).

1.0 INTRODUCTION

1.1 Project Background

The Genesis Solar Energy Project (referred to in this report as "Project") consists of two solar power electrical generating facilities (Units 1 and 2) with a combined net capacity of 250 megawatts. The Project facility consists collectively of two power blocks, power generating equipment (solar collector assemblies [SCAs] of mirrored parabolic troughs [solar troughs or troughs]), support facilities, and evaporation ponds. Linear facilities include a transmission line, distribution line, natural gas pipeline, and a main access road that are mostly co-located for approximately 10.5 km (6.5 miles). The Project comprises approximately 1,800 acres (728 hectares [ha]). The solar field and associated structures comprise 1,727 acres (699 ha) and linear facilities comprise 93 acres (38 ha). The Project is located on land managed by the Bureau of Land Management (BLM) 25 miles (40 kilometers [km]) west of Blythe, in Riverside County, California (Figure 1).

1.2 Monitoring Plan Overview and Goals

A Bird and Bat Conservation Strategy (2015; “BBCS”) was prepared by the Project proponent in collaboration with the U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), California Energy Commission (CEC), and Bureau of Land Management (BLM) to guide comprehensive monitoring of impacts to birds and bats associated with operation of the Project. Final agency acceptance of the BBCS occurred in March 2015.

The BBCS details post-construction monitoring to be conducted and the data analysis and reporting processes that will be implemented by Genesis Solar in collaboration with the USFWS, CDFW, CEC, and BLM. As identified in the BBCS, they are:

1. Estimate overall annual avian fatality rate and species composition associated with the Project infrastructure. This estimate will include mortality associated with SCAs, overhead lines including the generation (gen-tie) line, perimeter fence and other features of the Project that may result in injury and fatality.
2. Determine whether there are spatial and temporal/seasonal patterns of mortality associated with project infrastructure (e.g., different fatality rates near SCAs on the edge of the solar field versus the interior area of the solar field).
3. Provide information that will assist the CEC and BLM, in consultation with the USFWS and the CDFW, in understanding which species and potentially which regional populations are at risk.
4. Collect data in such a way that the CEC and BLM, in consultation with the USFWS and CDFW, may make comparisons with other solar sites.

1.3 Purpose of This Report

This report represents the second seasonal report for the first year of monitoring summarizing monitoring methods and results for avian and bat fatalities and injuries based on the procedures and requirements specified in the approved BBCS and as required by CEC Condition of Certification BIO-16. This report covers the 2015 summer season, which includes the period from June 01 to August 30, 2015. For logistical reasons, fall monitoring started on Monday, August 31, 2015. This report and the other interim quarterly reports are considered preliminary summaries of data and information for the seasonal monitoring periods. Final information from all four quarterly monitoring periods will be included in a comprehensive final annual report. As stated in the approved BBCS, this seasonal report includes the observed fatality rates broken out by likely diurnal, and likely nocturnal species, and for ecological guilds of interest (e.g., raptors, water-associated birds, passerines), for each of the facility types and suspected causes of death. Species composition of carcasses and the results of the bias trials are also reported. This report presents information related to the spatial distribution of carcasses, but no formal statistical analysis will be conducted until the end of the monitoring year, given the limited data presently available.

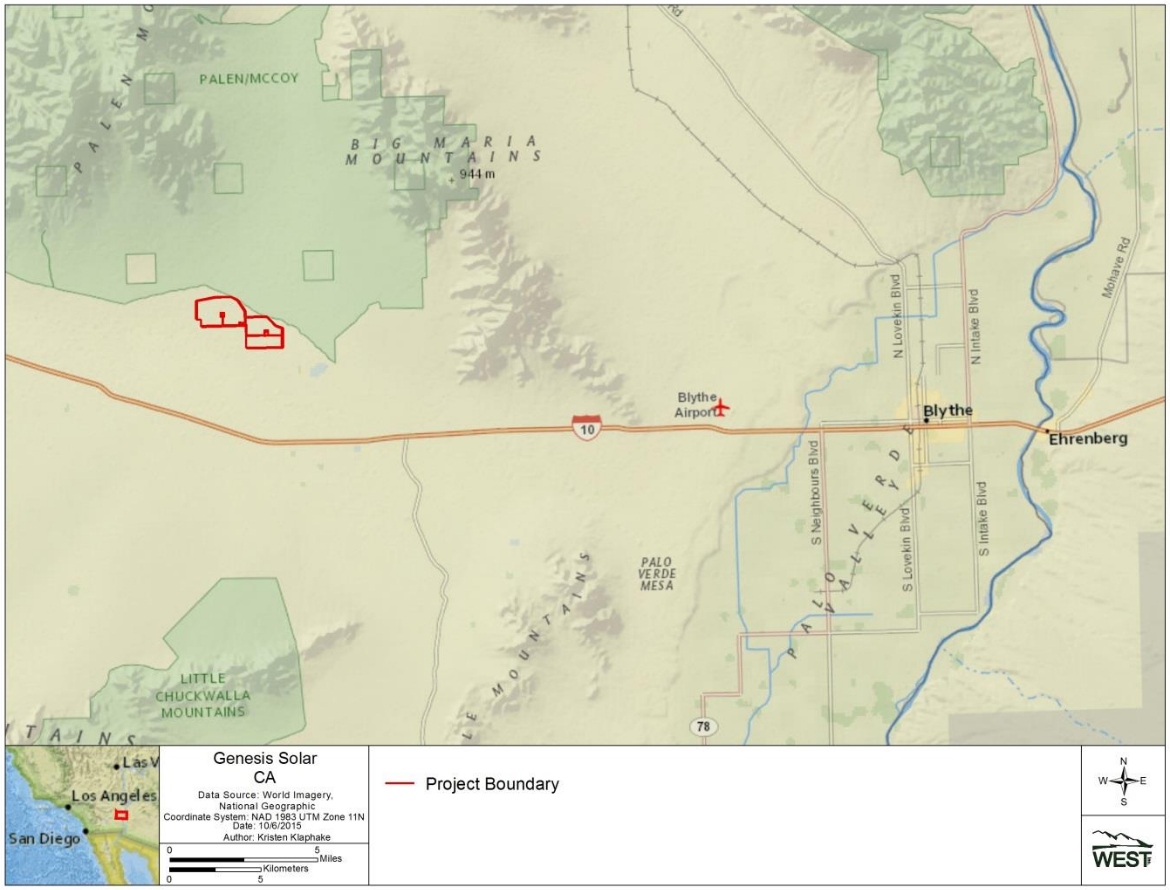

Figure 1. Genesis Solar Energy Project vicinity map, Riverside County, California.

2.0 METHODS

The BBCS describes the methods by which monitoring and certain analyses, including compilation of the overall fatality estimate, will occur. Below is an abridged description (see BBCS for detailed methods).

2.1 Standardized Carcass Searches

This section describes areas surveyed, the timing and frequency of searches, and the methods by which standardized searches were conducted to identify dead/injured birds and bats at the Project. This section also describes the methods for conducting carcass removal and searcher efficiency trials; how data were reported and analyzed; and the methods for producing fatality estimates for the Project.

2.1.1 Areas Surveyed

Standardized carcass searches were conducted at a sample of the solar collector assemblies in each unit; the perimeter of each power block (including the area below each air condensed cooling [ACC] unit; Figures 2 and 3); the “fenceline” defined as the perimeter fences for each unit (100% of the total length of fence; Figures 2 and 3); and the gen-tie and distribution lines (25% of the total length of each line from the Project fence to Wiley’s Well rest stop; Figure 4). Table 1 provides the total area of each component as well as the percent of each component that was searched.

To ensure a balanced distribution of plots in solar collector assemblies, each unit was divided into blocks, and each block was sampled using a systematic sample of 30% of pairs of rows with a random starting point. This sampling design ensures that survey plots were not spatially clumped.

2.1.2 Search Frequency and Timing

The summer survey season includes the period from June 01 through August 30, 2015. Standardized searches occurred at 21-day intervals beginning June 01, 2015. All project components included in standardized searches were surveyed four times. All searches took place during daylight hours from 06:30 to 17:00.

The average summer search interval was 18.9 days (median 21 days) for all Project components included in standardized carcass searches. Slight variation in search interval was anticipated due to weather and logistical delays.

Figure 2. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance) at Unit 1 of the Genesis Solar Energy Project summer (June 01 – August 30) 2015.

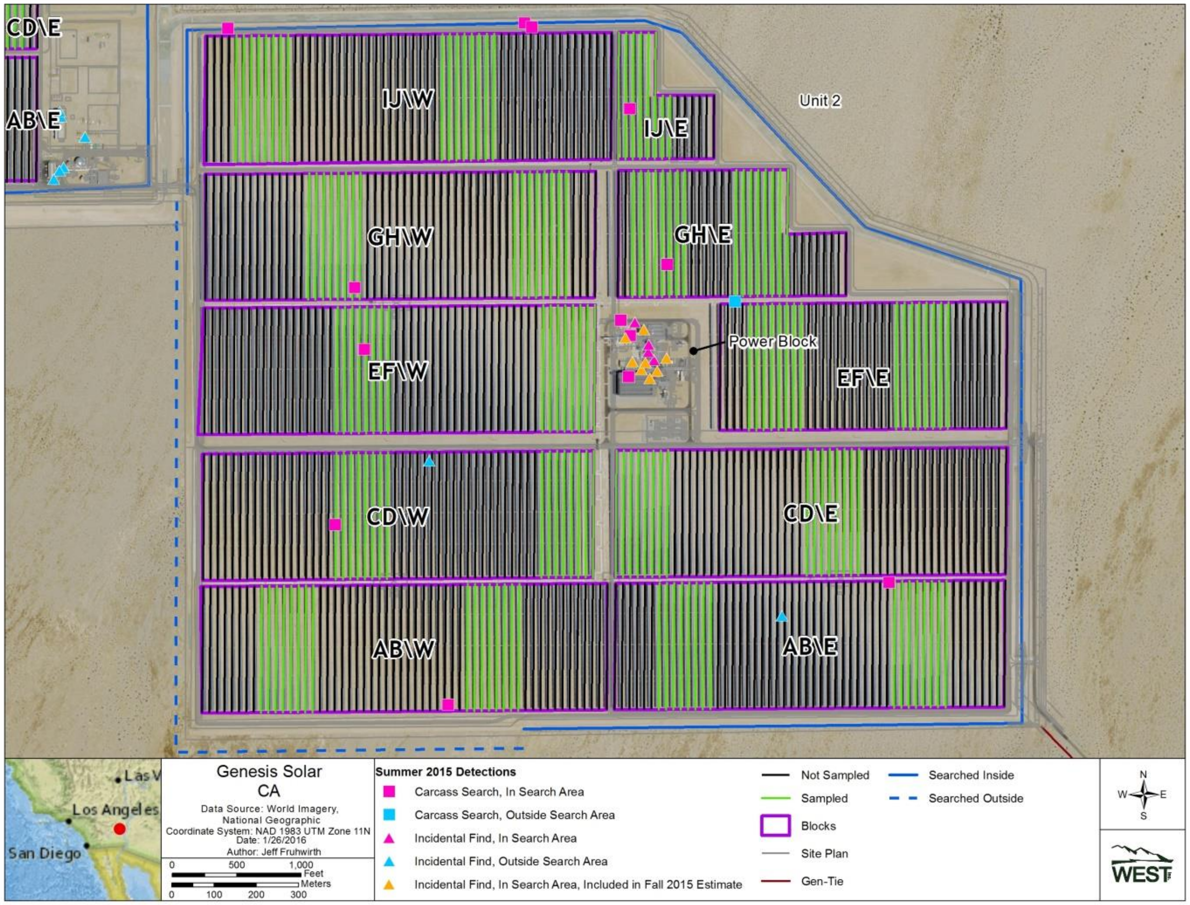

Figure 3. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance) at Unit 2 of the Genesis Solar Energy Project during summer (June 01 – August 30) 2015.

Table 1. Areas included in standardized carcass searches at the Genesis Solar Energy Project during summer (June 01 – August 30) 2015.

Project Component	Total Size	Units	Percent of Component Searched
SCAs	920	rows of solar troughs	30.4
Unit 1	460	rows of solar troughs	27.8
Unit 2	460	rows of solar troughs	33.0
ACC units	0.9	hectares	100
Power block (perimeter)	0.8	kilometers	100 of perimeter
Evaporation ponds	3.1	hectares	100
Distribution line	8.4	kilometers	25.0
Generation Tie line	8.4	kilometers	25.0
Fence	14.5	kilometers	100

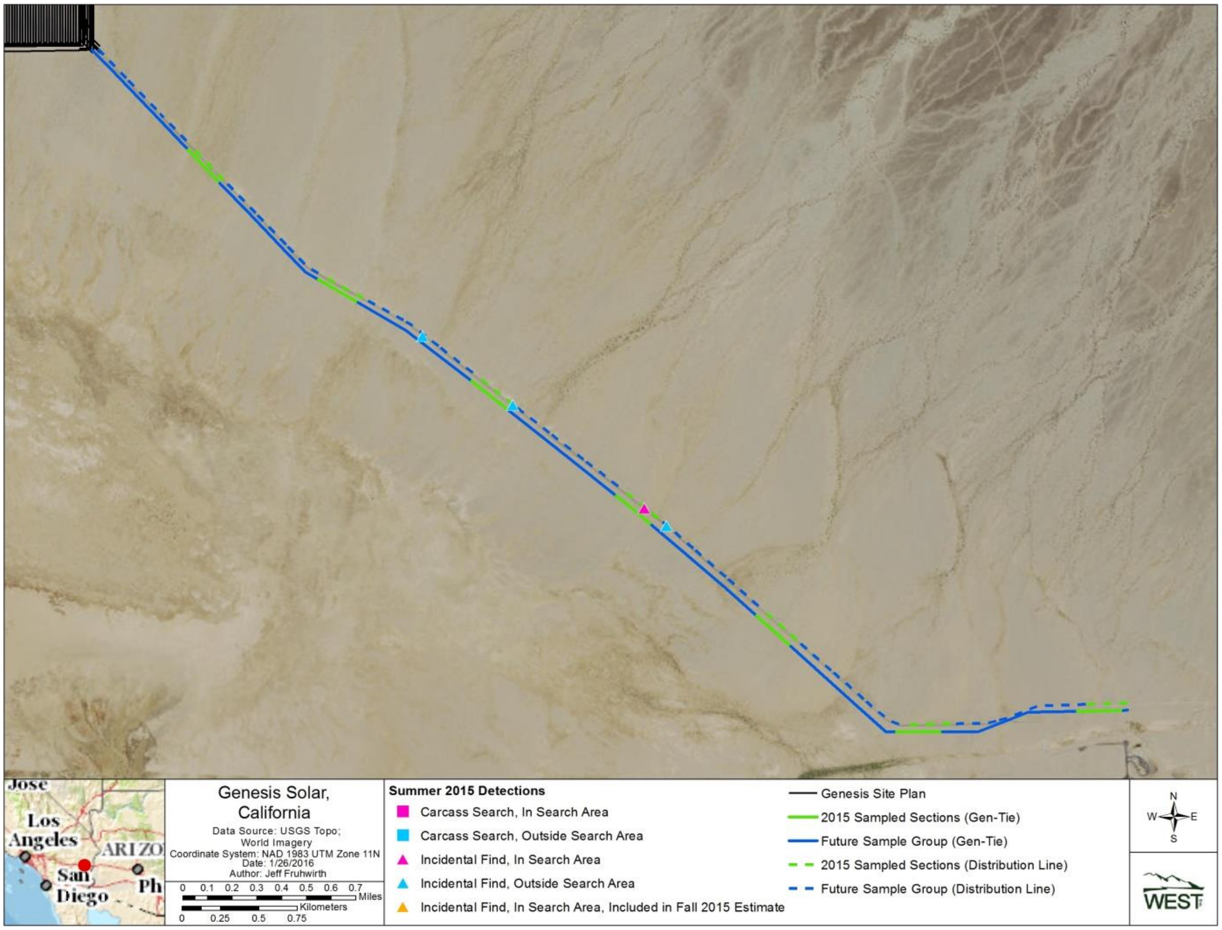

Figure 4. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance activities) along the distribution and generation tie lines and Project access road at the Genesis Solar Energy Project during summer (June 01 – August 30) 2015. Detailed maps of detections are presented in Appendix C.

2.1.3 Search Methods

Standardized carcass searches were performed by CEC- and BLM-approved biologists, in accordance with methods outlined in the BBCS.

Within the solar collector assemblies, 280 solar troughs (30.4% of the total number of troughs) were surveyed by vehicle. Biologists slowly drove (≤5 mph) parallel to troughs and centered between rows, searching ahead and to the driver's side of the vehicle for bird and bat carcasses. Biologists scanned out to a perpendicular distance of approximately 30 m, or the ground area encompassing two rows of solar troughs.

At each power block, biologists slowly walked around the entire perimeter looking for dead and injured birds and bats, and used binoculars to scan interior portions of the powerblock. Per site safety rules, the biologists are not allowed to walk in the interior of the powerblock. However, site personnel do safety inspections and other maintenance on a daily basis within the powerblock. Correction factors for the powerblock Beneath ACC units, biologists walked four evenly-spaced transects (approx. 15-m apart) through the gravel. The search area for the power block is defined as the 0.8-km perimeter of each power block, and the area of the interior power block that was available for visual inspection from the periphery.

At each evaporation pond, biologists walked the entire perimeter looking for dead and injured birds and bats on the ground, in the netting, and in the pond below the netting. Binoculars or a spotting scope were used to scan across the top of the netting and the surface of each pond.

The entire length of fenceline (approximately 12 miles) was searched by vehicle. Biologists searched an approximately 1.5 to 2.5 miles (2.4 km) along drivable sections of the outside of the fence, and the remaining 9.5 to 10.5 miles (16.9 km) were surveyed from the inside of the fence (Figures 2 and 3). Travel speed was below five mph while searching.

The gen-tie and distribution lines were each surveyed using a 30-m wide strip transect (i.e., 15 m of ground on either side of the overhead line). A 25% sample of both lines from the Project fence to the Project outer gate located near the Wiley's Well Road rest stop were searched for carcasses. Biologists slowly walked every fourth 300-ft segment of each line, scanning for dead or injured birds or bats within 15 m (49.2 ft) of the transect line. Given the location of the lines relative to the road, detections found in the strip transects below overhead lines could be caused by collision with an overhead line, vehicles along the road, or some combination of both.

As soon as a carcass was detected, it was then photographed, and data were recorded according to specifications outlined in section 6.7 of the approved Genesis BBCS. Carcasses were then immediately retrieved from their location on the ground, labeled, and placed in a freezer on site.

Suspected cause of death was assigned based on evidence available on the detection, evidence available on the Project infrastructure, and proximity of a detection to Project infrastructure. Detections that had evidence of scavenging and lacked evidence on Project infrastructure were assigned as “unknown” because it can’t be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging), located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines), and had evidence of injury on the detection had a suspected cause of death attributed to the respective Project component. However, it should be noted that there is uncertainty associated with cause of death assignments because no events were directly observed.

2.2 Carcass Persistence Trials

Carcass persistence trials were conducted throughout the summer period. Carcasses from three size classes (small [0-100 g], medium [101-999], and large [1000+ g]) were used for trials. Carcass persistence results from small birds were used as a proxy for bat carcass persistence. The small size class comprised house sparrows (*Passer domesticus*) and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons (*Columba livia*), chukar (*Alectoris chukar*) and older coturnix quail, and the large size class comprised hen mallard (*Anas platyrhynchos*) and hen ring-necked pheasant (*Phasianus colchicus*).

2.2.1 Carcass Persistence Data Collection

To quantify carcass persistence rates, 15 small, 10 medium, and five large carcasses were randomly placed and monitored within the solar field (SCA’s and the fence line), and the same number of each size class were placed along the gen-tie and distribution lines, for a total of 60 carcass persistence trials at Genesis during the summer 2015 season, as specified in section 6.5 of the approved Genesis BBCS. Fifteen carcasses within the Project fence (within SCAs and along the fence and perimeter of power blocks) and four carcasses along the gen-tie and distribution lines were monitored using motion-triggered digital trail cameras, while the remaining carcasses were visited on foot, for 30 days or until the carcass had deteriorated to a condition at which it would no longer qualify as a documentable fatality (i.e., a feather spot). Fewer carcasses along the gen-tie and distribution lines were monitored with cameras because of theft and vandalism concerns. Carcasses without trail cameras were visited and photographed once per day for the first four days, and then every three to five days until the end of the monitoring period. To avoid training scavengers to recognize cameras as “feeding stations”, trail cameras were installed five days before specimens were placed, and fake cameras without bias trial carcasses were also placed (eight within the Project fence, and four along the gen-tie and distribution lines). Periodic ground-based checking of carcasses with trail cameras also occured to guard against misleading indicators of carcass removal, such as wind blowing the carcass out of the camera’s field of view. To minimize potential bias caused by scavenger swamping (Smallwood 2007, Smallwood et al. 2010), carcass-persistence specimens were distributed across the entire Project, not just in areas subject to standard searches, and trials were initiated in small numbers on four different dates throughout the spring season.

2.2.2 Estimating Carcass Persistence Times

Carcass persistence trials were checked daily during the first four days and then every three to five days until the 30-day trial length was reached. Measurements of carcass persistence rates were subject to censoring. In this context, censoring refers to the instance when a value (e.g. days a carcass is present before being removed) may not be known exactly, but is known to be within a finite range. For example, suppose a carcass was checked on day 7 and was present, and was checked again on day 10, but was found to be missing. The exact time until removal is unknown; however, it is known that the carcass became unavailable at some point between 7 and 10 days. This carcass would be considered “interval censored”. Similarly, if a carcass lasts the entire 30-day trial period, that carcass is “right censored”— it is known that the carcass lasted at least 30 days, but it may have persisted longer. Because carcass persistence data were censored, persistence was analyzed using methods that can accommodate censored data and still produce unbiased estimates of the probability of persistence (Therneau 2015, Thernaur and Grambsch 2000). It is beyond the scope of this document to provide statistical foundations of censored-data survival models but functions identical to those provided with the USGS-developed fatality estimator software (Huso et al 2012) were used to fit survival models to the censored carcass persistence data, and some background is available in the documentation provided with that software.

USGS-developed fatality estimator software (Huso et al. 2012) was used to fit survival models to the censored carcass persistence data. There were four distributions implemented in survival models used to estimate the probability a carcass is unscavenged and available to be found at the end of the search interval (*r*): exponential, Weibull, loglogistic, and lognormal. These four distributions exhibit varying degrees of flexibility in order to model a wide variety of distributions of persistence time. Akaike’s Information Criterion adjusted for sample size (AICc; Akaike 1973) was used to rank the fit of each survival model to censored carcass persistence data.

2.3 Searcher Efficiency Trials

Searcher efficiency trials were conducted throughout the summer period. Carcasses from three size classes (small, medium, and large) were used for trials. Searcher efficiency results from small birds were used as a proxy for bat detection. The small size class comprised house sparrows and 2-3 week old coturnix quail, the medium size class comprised rock pigeons, chukar, and older coturnix quail, and the large size class comprised hen mallards and hen ring-necked pheasants.

2.3.1 Searcher Efficiency Data Collection

A total of 60 searcher efficiency trials (15 small birds, 10 medium birds, and five large birds within SCA’s, power blocks, and along the perimeter fence, and the same number of each size class along the gen-tie and distribution lines) were placed at the Project during the 2015 summer season, as specified in section 6.4 of the approved Genesis BBCS. Locations for trials were chosen by taking a randomized sample of all locations included in standardized carcass searches. Trial carcasses were placed in various vegetation heights and in areas that had different soil and vegetation colors and values to represent the range of conditions under which searches occur. They were placed in all areas where standardized searches occur except the evaporation ponds. Trial carcasses were placed in selected search areas the same morning that a search is scheduled to occur in that area. Trial carcasses were retrieved the same day, either by the searcher who found them, or for missed carcasses, by the observer who conducted the searcher efficiency trial.

2.3.2 Estimating Searcher Efficiency

There were not sufficient data for the summer season to assess whether searcher efficiency differed by Project component (e.g., SCAs/fence/power block [solar field] versus gen-tie/distribution line [overhead lines]), so searcher efficiency was assumed to differ between the two areas and was estimated separately for the solar field and overhead lines. The nearly complete lack of vegetation cover in the solar field suggests that searcher efficiency may be higher in the solar field than along the overhead lines where vegetation cover is greater. If this hypothesis is true, accounting for this difference in searcher efficiency across Project components will be important for producing accurate fatality estimates at the end of the monitoring year.

To evaluate hypotheses regarding differences in carcass detectability among carcass size and visibility classes, logistic regression models were fit to searcher efficiency data and AICc was used to compare models. Models including effects of carcass size (3 classes), season (spring, summer) and visibility index (2 classes) were compared to each other and a null model. The two visibility classes present at the Project site are: easy (defined as ≥ 90% bare ground [BG]; vegetation <6” tall) and moderate (defined as 26-89% BG; vegetation <6” tall). However, within the solar field the moderate visibility class has a very limited spatial extent (approximately 10%) due to management aimed at minimizing vegetation cover and thus, was represented by only two trial carcasses during the reporting period. Rather than eliminating the two carcasses in the moderate class from the analysis of searcher efficiency, we assumed there were no differences in searcher efficiency between the two visibility classes in the solar field this summer, and the set of candidate models for searcher efficiency (within the solar field only) did not include tests of the hypothesis that searcher efficiency varied between visibility classes. The spatial extent of the moderate visibility class in the solar field is roughly equal to its representation in the summer sample of searcher efficiency carcasses (8 of 60 or 13.3%).

Once the best model was chosen and appropriate classes identified, searcher efficiency, or the proportion of carcasses detected, *p,* was calculated for each class using the following equation:

$$p = \frac{Number\ of\ Carcasses\ Observed}{Number\ of\ Carcasses\ Available}$$

The data for this analysis included all searcher efficiency trial carcasses from the spring and summer 2015 season, because model selection results indicated no differences in searcher efficiency by season.

2.4 Fatality Estimator

Fatality rate estimation is a complex task due to several variables inherent to every fatality monitoring study. Carcasses may persist for variable amounts of time due to local scavenger activity or environmental conditions leading to carcass degradation over time. Carcasses and feather spots are also detected with varying levels of success based on carcass characteristics and ground cover (e.g., vegetated areas underneath the gen-tie and distribution lines versus cleared areas beneath SCAs). For these reasons, it is generally inappropriate to draw conclusions based on the raw number of fatalities alone. The desire to estimate fatalities given these variables has driven the development of several statistical methods for estimating fatalities (e.g., Smallwood 2007, Huso 2010, Korner-Nievergelt 2011). All of these fatality estimation methods share a similar underlying model. Generally, the fatality estimation for a given site may be written as:

$$F=C/rp,$$

where F is the total number of fatalities, C is the number fatalities detected and included in fatality estimation, r is the probability a carcass is unscavenged and available to be found at the end of the search interval, and p is the probability of detecting a carcass (Huso 2010).

All fatality estimates were calculated using the Huso estimator, as well as 90% confidence using bootstrapping (Manly 1997). Bootstrapping is a computer simulation technique that is useful for calculating point estimates, variances, and confidence intervals for complicated test statistics. A total of 1,000 bootstrap replicates were used for each variable including searcher efficiency (p), probability of a carcass persisting to the next search ($\hat{r}$), adjusted search interval and observed fatalities. From these bootstraps, the probability of available and detected was calculated and applied to the bootstrapped observed fatalities. The lower 5th and upper 95th percentiles of the 1,000 bootstrap estimates provide estimates of the lower limit and upper limit of an approximate 90% confidence interval on all estimates.

2.5 Incidental Reporting

Some detections were outside standardized search areas, or were within search areas but not observed during standardized searches. Such detections were found by WEST avian biologists and operational personnel and were considered “incidental” detections. When found by operational personnel, these detections were reported to WEST avian biologists for documentation. Data on incidental detections are reported here, as well as in the SPUT Avian Injury and Mortality Report Forms June – August 2015. All detections made in search areas were included in fatality estimates, regardless of whether they were detected incidentally or during searches.

3.0 MONITORING RESULTS

3.1 Summary of Avian Detections

During summer 2015, a total of 60 detections (including stranded birds, incidental detections, and bats) of 32 identified species were recorded (Table 2). The most numerous detection of an identified species was of brown-headed cowbird (*Molothrus ater*), and greater roadrunner (*Geococcyx californianus*), each with five detections. Most detections (n = 22, or 36.7% of total detections) occurred at powerblocks (Figures 2, 3; Tables 2, 3, and 4). Twenty-four (40.0%) detections were made during standardized carcass searches and 36 (60.0%) were documented as incidentals with most of these (n = 17) in the powerblock.

Table 2. Number of individual detections (those made during standardized carcass searches and incidentally), by species and component, during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California. SCA = solar collector trough.

3.2 Temporal Patterns of Avian Detections

The number of detections recorded daily during summer 2015 ranged from zero to five (Figure 5). The period from June 01 to August 30 was characterized by peaks in detections with highs on June 29, July 2, and August 17. The fewest detections in any calendar month was July. The number of detections per day represents those discovered during standardized carcass searches and incidentally.

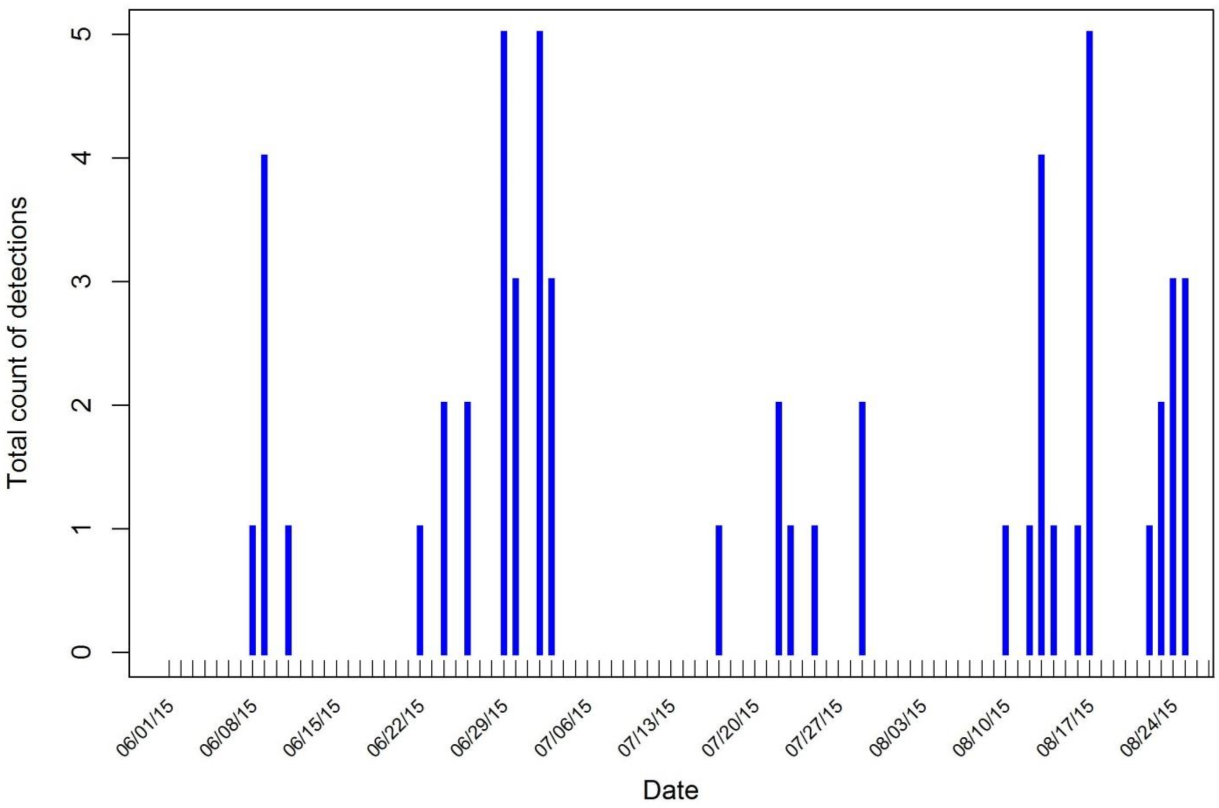

Figure 5. Total number of detections by date during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California.

3.3 Spatial Distribution of Avian Detections

3.3.1 Detections by Project Component

During summer 2015, detections were documented from Project buildings, the perimeter fence, gen-tie and distribution lines (overhead lines), the power block or ACC unit within the power block, evaporation ponds, and SCAs (Tables 2, 3, and 4). Of the 56 detections within the solar units, 27 (48.2%) were detected in Unit 1, and 29 (51.8%) were detected in Unit 2.

Table 3. Total detections by Project component and detection category during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California.

Project Component	Carcass search	Incidental	Percent of Total
Buildings	0	6	10.0
Fence	4	0	6.7
Overhead lines	0	4	6.7
Ponds	5	3	13.3
Power Block	5	17	36.7
SCA	10	6	26.7
Percent of Total	40.0	60.0	100.0

Table 4. Total detections (including incidentals) by Project component and suspected cause of death during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California.

	Suspected Cause of Death*						
Project Component	**Collision**	**Drowned**	**Entangled**	**Other**	**Predation**	**Unknown**	**% of Total**
Fence	0	0	0	2	0	2	6.7
Other	1	0	0	1	0	4	10.0
Overhead lines/road	2	0	0	1	0	1	6.7
Pond	1	0	2	3	0	2	13.3
Powerblock	7	1	0	8	0	6	36.7
SCA	4	0	0	8	1	3	26.7
% of Total	25.0	1.7	3.3	38.3	1.7	30.0	100.0

* Suspected cause of death was assigned based on evidence available on the detection, evidence available on Project infrastructure, and proximity of detection to Project infrastructure. Detections that had evidence of scavenging and lacked evidence on Project infrastructure were assigned as "unknown" because it can't be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) and had evidence of injury on the detection had a suspected cause of death attributed to the respective Project component. However, in the absence of completed necropsy, there is some uncertainty associated with cause of death assignments because no events were directly observed.

3.3.2 Feather Spot Detections

Twelve (20.0%) of the 60 detections made during summer 2015 consisted only of feather spots. Along the fence, three of four total detections (75.0%) were feather spots. No detections along the overhead lines and road or the evaporation ponds were feather spots. Three of 22 total detections (13.6%) at the powerblocks were feather spots. Six of 16 total detections (37.5%) at SCA's were feather spots.

3.4 Detections of Stranded Birds

There were no detections of stranded or injured birds during the 2015 summer season.

3.5 Summary of Bat Detections

Five bats were detected during the summer season. Idenitified species included Mexican free-tailed (*Tadarida brasilinesis*; 1), and canyon bat (*Pipistrellus hesperus*; 2; Table 2).

3.6 Carcass Persistence Trials

Data from carcass persistence trial carcasses were available from spring and summer at the solar field (SCA's, powerblocks, and perimeter fence) and overhead lines (n = 30 each or 120 total). Of these, only seven trials were not in easy visibility habitats, so visibility was not included as a covariate in the carcass removal models. Preliminary analysis using AICc suggested that both season and location (lines vs. solar field) were important predictors of carcass persistence, but when the data were separated by location, season was only important for carcasses within the solar field. Therefore, two carcass persistence models were fitted to two different sets of data: 60 carcasses total from spring and summer were used to estimate carcass persistence along overhead lines, and 30 carcasses total from summer only were used to estimate carcass persistence within the solar field.

Using carcass persistence data from 2015 spring and summer seasons as outlined above, survival models were compared for relative quality using the corrected AICc score, as suggested in Huso (2010). The AICc score provides a relative measure of model fit and parsimony among a selection of candidate models. The model with lowest AICc is typically chosen as the "best" model relative to other models tested; however, any model within two AICc points of the best model is considered competitive with the best model (Burnham and Anderson 2004).

For data collected at SCAs, the top two models had ∆AICc values <2. Ultimately, the loglogistic model that included an effect of carcass size was chosen as the most parsimonious of the top models. The chosen model predicted that 52% (45 – 64%) of small carcasses, 92% (76 – 96%) of medium carcasses, and 100% of large carcasses persisted for a standard 21-day search interval. Mean (median) removal time for small carcasses in the solar field was 8.0 (9.0) days, 35.1 (30.0) days for medium carcasses, and was not estimated for large carcasses given the nearly perfect persistence rate (no removal was observed; Figure 6).

For data collected along the overhead lines, the top six models had ∆AICc values <2. Ultimately the lognormal model with an effect of carcass size was chosen as the most parsimonious top model. The chosen model predicted that 14% (9 – 20%) of small carcasses, 59% (42 – 74%) of medium carcasses, and 41% (26 – 58%) of large carcasses persisted for a standard 21-day search interval. Mean (median) removal time along overhead lines for small carcasses was 0.8 (0.5) days, for medium carcasses was 12.8 (30.0) days, and for large carcasses was 4.6 (3.5) days (Figure 6). The difference in carcass removal times between Project components is because scavengers likely occur in higher densities outside the perimeter fence.

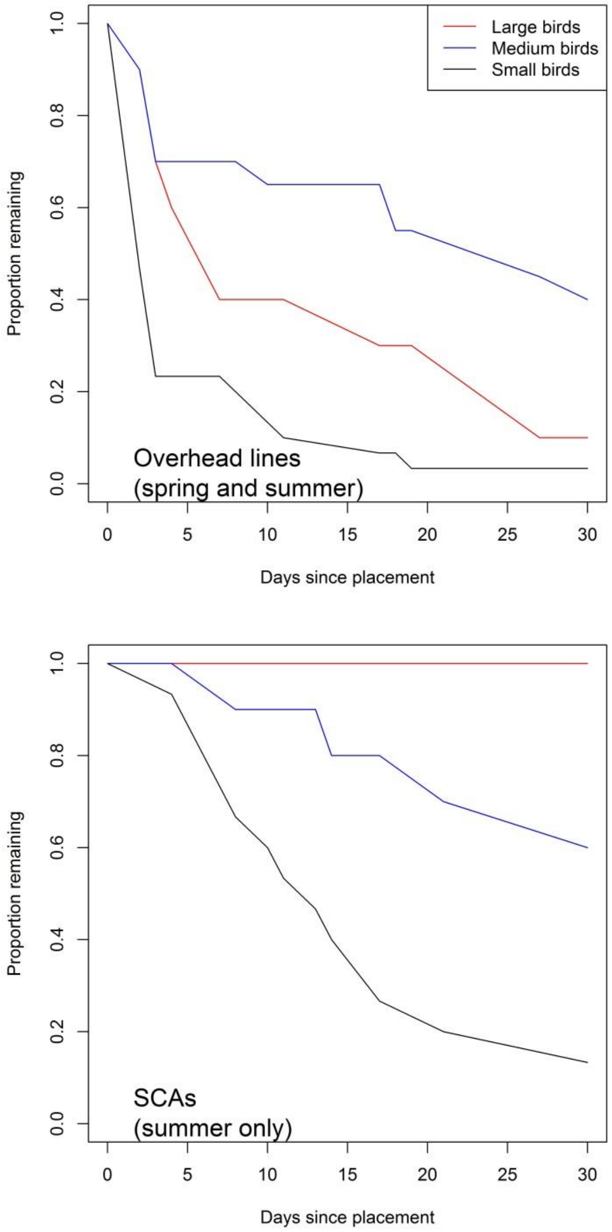

Figure 6. Proportion of trial carcasses remaining as a function of days since placement and carcass size class during the summer 2015 season at the Genesis Solar Energy Project, Riverside County, California. Modeling of carcass persistence data from overhead lines suggested no effect of season, so sample size used to produce the overhead lines panel was n = 30, 20, and 10 for small, medium, and large size classes, respectively. Modeling of carcass persistence data from the solar field (SCAs) suggested an effect of season, so sample size used to produce the SCA panel was n = 15, 10, and 5 for small, medium, and large size classes, respectively.

3.7 Searcher Efficiency Trials

During the 2015 summer season, a total of 60 searcher efficiency trials (30 small, 20 medium, and 10 large birds) were placed at the Project. Details regarding the number of searcher efficiency trial carcasses placed, removed, and available to be found by Project component are provided in Table 5. All carcasses removed by scavengers during searcher efficiency trials are assumed to have been removed before the observer had a chance to detect the trial carcass. Our analysis assumes the trial carcasses are removed at random and that the remaining carcasses provide a fair indication of our searcher efficiency.There was one observer at Genesis during summer; Sarah Nichols was tested throughout the summer season, and there were 51 trial carcasses available for her to find.

Table 5. Searcher efficiency trial carcass locations by Project component during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California.

Project Component	Placed	Removed	Available to be detected
Fence	6	4	2
Gen-tie line	15	1	14
Distribution line	15	1	14
Powerblocks	3	0	3
SCA's	21	3	18
Total	60	9	51

In the solar field (SCAs + fence + powerblocks), the null model was chosen as the best model to estimate searcher efficiency, suggesting no effect of carcass size, season, or visibility class. Thus, data from spring and summer searcher efficiency trials, all carcass class sizes, and both visibility classes were pooled for the following estimate of searcher efficiency. Searcher efficiency rate in the solar field was 91.8% (86.0 – 98.0%), or 45 found of 49 available to be found.

Along overhead lines, the model that included an effect of carcass size, but not season or visibility class, was chosen as the best model. Thus, data from spring and summer trials and both visibility classes were pooled for the following estimates of searcher efficiency along overhead lines: 53.6% for small birds (39.0 – 68.0%; 15 found of 28 available to be found), 100% for medium birds (19 found of 19 available), and 100% for large birds (10 found of 10 available). Although carcass size influenced searcher efficiency, searcher efficiency was relatively high over all carcass size classes (77.1%).

3.8 Fatality Estimates

Fatality estimates were calculated separately for each component (SCAs, power blocks, fence, evaporation ponds, and overhead lines/road). Ultimately, no detection was excluded from the fatality analysis because it was estimated to be older than the 21-day search interval (Huso 2010). Of the 60 detections that occurred in summer, 16 were excluded from the summer fatality estimate because they were found outside standardized search areas, and 12 were excluded because they were found after the last standardized search in summer (to be included in fall 2015 estimates; Table 6, Appendix B).. However, all detections that occurred during summer are reported in Table 2. Detections used in the analysis, bias corrections, summer fatality estimates, and 90% confidence intervals for summer fatality estimates are detailed in Appendix B.

Table 6. Status of detections during the summer (June 01 – August 30) 2015 season at the Genesis Solar Energy Project, Riverside County, California. All detections outside the search area were excluded from the fatality analysis, regardless of whether they occurred during a standardized carcass search or incidentally.

	Carcass search	Incidental detection	*Pushed to next season's fatality estimate	*Pulled from previous season's fatality estimate
Inside search area	22	10	12	0
Outside search area	2	14	0	0

* Incidental detections occurring after the last standardized carcass search in a season are considered for inclusion in the fatality analysis for the following season. This is consistent with the assumption we make throughout the monitoring seasons; that carcasses found incidentally would have been available to be found on the next scheduled search. This assumption may result in some carcasses found during one season but considered in the following season's fatality analysis. Once a carcass has been moved to a different season's analysis it is still subject to the same criteria for inclusion or exclusion based on location (in versus out of a searched area) and carcass age (greater than versus less than the search interval).

Using the Huso (2010) fatality estimator model, during the summer period 2015, there were an estimated total 100 carcasses (90% CI: 81 - 145) at the Project. Of these, 53 carcasses (53%) were estimated for the SCAs, 8 carcasses (8%) were estimated for the fence, 9 carcasses (9%) were estimated for evaporation ponds, 23 carcasses (23%) were estimated for power blocks[1], and 7 carcasses (7%; CI: 6 – 21) were estimated for the overhead lines and project road. An estimated 93 (93%; CI: 66-126) carcasses (0.050/acre, (50/1000 acres, 0.37/nameplate MW)

---

[1] Estimate is based on adjusted mortality from the powerblock perimeter surveys and adding in the incidentals found by operations staff in the interior of the powerblock. The carcasses found by staff in the interior of the powerblock are not adjusted for biases because no trials are conducted in those areas (biologists are not allowed in that area for safety reasons). However, daily surveys are conducted throughout the interior of the powerblock by operations staff for equipment inspections, and several personnel spend time in those areas on a daily basis.

occurred for all components associated with both solar units (SCAs, power block, evaporation ponds, and along the perimeter fence, combined). A complete list of estimates for each Project component and carcass size class with confidence intervals is presented in Appendix B.

4.0 DISCUSSION

The 2015 summer season represented the second season of standardized monitoring at Genesis per the BBCS. Searcher efficiency trials and carcass removal trials were conducted concurrently at the SCAs, power blocks, fencelines, and along the gen-tie and distribution lines. Data from these trials were used to produce fatality estimates adjusted for searcher efficiency and carcass persistence bias. Although these estimates were produced from a statistically robust sample, only limited inference may be drawn from a single season of data. These results should be considered preliminary because estimating carcass persistence, searcher efficiency, and adjusted numbers of fatalities within each season represents information based on a limited sample size. As more data are collected throughout the monitoring year (and additional quality assurance/quality control measures occur, for example characterizing feather spots to species or size class), data from all seasons may be pooled. At that time, data will be tested for seasonal differences retrospectively using an information-theoretic approach, but because seasonal estimates will be produced from the much larger annual data set, they may differ from what is reported here because they are based on a larger, more informative sample.

4.1 Carcass Persistence and Searcher Efficiency Trials

The degree to which carcasses persist on the landscape depends on a variety of factors reflecting seasonal and inter-annual variation in habitat, climate, and the scavenger community. The composition and activity patterns of the scavenger community often vary seasonally as birds migrate, new juvenile birds and mammals join the local population, and mammalian scavengers variably hibernate or estivate. The scavenger community may also vary substantially from year to year because of variation in annual reproduction and survival related to changes in landscape condition. Climatic conditions that vary seasonally and annually also may contribute to variation in carcass decay and removal rates due to variation in temperatures, solar insolation, wind patterns, and the frequency of flooding events. Thus, rates of carcass persistence reported here should be interpreted cautiously as they may change over the coming months.

Fatality estimates are influenced by the relationship between carcass removal dynamics and search intervals. In practical terms, longer search intervals reduce average probability that a carcass persists until the next search. In terms of the analysis, this can manifest as a lower probability of persistence through the effective search interval, or an effective search interval that is shorter than the nominal search interval. In either case, the adjustment to carcass counts due to carcass removal dynamics is calculated as

$$\frac{length\ of\ effective\ search\ interval}{\begin{array}{c} length\ of\ nominal\ search\ interval * average\ probability\ of\ persistence \\ through\ the\ effective\ search\ interval \end{array}}$$

The adjustment to estimated fatality for carcass removal increases with longer search intervals, and the variance in the estimate may increase, also.

Searcher efficiency was influenced by carcass size, but it is not yet clear if there may be an effect of habitat visibility class due to limited sample sizes. In the SCA's, searcher efficiency was high regardless of carcass size and this is likely influenced by the limited vegetation cover beneath solar troughs. Beneath overhead lines outside the Project fence vegetation cover is higher, but our analysis did not support the hypothesis that visibility class is a factor in searcher efficiency along the lines. Carcass size influenced searcher efficiency, but searcher efficiency was relatively high over all carcass size classes (77.1%).

Searcher efficiency trials for this Project will be repeated seasonally. The desert landscape in which this Project is located generally changes little with the seasons, save for brief periods following seasonal rains when floods may occur and blooming plants may flourish. A recent meta-analysis involving data from more than 70 wind-energy projects suggested that including habitat visibility class as a predictive variable generally eliminated any otherwise apparent seasonal effects on searcher efficiency (Smallwood 2013). Further, the possibility exists that searcher efficiency varies seasonally in some cover types but not others. Data from searcher efficiency trials conducted over the coming seasons will therefore continue to be tested for effects of habitat visibility class rather than effects of season.

4.2 Distribution of Fatalities and Fatality Estimates

The number of detections was highest during the early and late summer monitoring period and lowest during July. However, because this report includes detections made during carcass searches and incidental detections reported by Genesis site personnel between searches, patterns may reflect the 21-day search interval during summer more than any patterns in bird activity at the Project.

Composition of summer detections included avian species from 13 guilds. No single guild comprised a large number of detections: the most common was blackbirds/orioles (eight detections or 14.5% of all avian detections). Shorebirds and waterbirds/waterfowl were represented by six (10.9%) and seven (12.7%) detections, respectively. Summer was the first season in which bats were detected.

Detections attributed to an unknown cause accounted for approximately 30% of all detections during the 2015 summer season, and the distribution of the unknown cause detections varied by project component with the highest percentage of unknowns (66.7%, or 4 of 6 total detections) occurring in association with Project components that are not included in standardized carcass searches (e.g., buildings). Of the 18 detections attributed to an unknown cause, 4 (22.2%) were feather spots. Determining a cause of mortality from a feather spot is challenging because there is rarely visible evidence available on which to determine a cause of death. Thus, feather spots with an unknown cause of mortality could be encountered anywhere birds occur, and an unknown cause of a sizeable proportion of the carcasses is not unique to the Project. Further, game cameras trained on carcasses for carcass persistence trials at the Project have documented multiple feather spots originating from a single trial carcass. Ravens and turkey vultures, and possibly roadrunners, dislodge feathers from their attachment to the skin during the scavenging process. There are a very large number of potential feather spots present on a single bird carcass (because a feather spot is defined as at least two or more primary flight feathers, at least five or more tail feathers, or two primaries within five m (16.4 ft) or less of each other, or a total of 10 or more feathers of any type concentrated together in an area of three square m). Thus, the presence of feather spots among the detections for the Project may inflate the fatality estimate based on the potential for multiple feather spots resulting from one fatality to be counted separately if feathers are blown around the site or scattered by predators (e.g., plucking by ravens), feather spots resulting from predation not associated with the facility, or other causes. However, feather spots are included in the analysis here to provide a more conservative estimate of fatality.

[1] Estimate is based on adjusted mortality from the powerblock perimeter surveys and adding in the incidentals found by operations staff in the interior of the powerblock. The carcasses found by staff in the interior of the powerblock are not adjusted for biases because no trials are conducted in those areas (biologists are not allowed in that area for safety reasons). However, daily surveys are conducted throughout the interior of the powerblock by operations staff for equipment inspections, and several personnel spend time in those areas on a daily basis.

Figure C-2. Detailed map sections of detections along the distribution and generation tie lines of the Genesis Solar Energy Project during summer (June 01 – August 30) 2015.

Appendix D. Individual detections made during standardized carcass searches and incidentally, by species, during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California. SCA = Solar collector trough.

Table D-1. Number of individual detections (those made during standardized carcass searches and incidentally), by species, during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California. SCA = Solar collector trough.

Common Name	Scientific Name	Migration Behavior*	Guild	Count	Project Component
American kestrel	*Falco sparverius*	resident	Falcons	1	Powerblock
bank swallow	*Riparia riparia*	diurnal	Swallows	1	Powerblock
belted kingfisher	*Ceryle alcyon*	nocturnal	Kingfishers	1	Powerblock
black phoebe	*Sayornis nigricans*	variable	Flycatchers	1	Powerblock
brown-headed cowbird	*Molothrus ater*	diurnal	Blackbirds/Orioles	1	Other
				2	Powerblock
				2	SCA
California gull	*Larus californicus*	diurnal	Shorebirds	1	SCA
canyon bat	*Pipistrellus hesperus*	nocturnal	Bats	2	Other
cinnamon teal	*Anas cyanoptera*	nocturnal	Waterbirds/Waterfowl	1	Pond
				1	SCA
cliff swallow	*Petrochelidon pyrrhonota*	diurnal	Swallows	1	Powerblock
common nighthawk	*Chordeiles minor*	variable	Goatsuckers	1	Pond
eared grebe	*Podiceps nigricollis*	nocturnal	Waterbirds/Waterfowl	1	Pond
Eurasian collared-dove	*Streptopelia decaocto*	resident	Doves/Pigeons	1	Other
Gambel's quail	*Callipepla gambelii*	resident	Upland Game Birds	1	Fence
greater roadrunner	*Geococcyx californianus*	resident	Cuckoos	1	Overhead lines
				3	Powerblock
				1	SCA
lesser nighthawk	*Chordeiles acutipennis*	diurnal	Goatsuckers	1	Overhead lines
loggerhead shrike	*Lanius ludovicianus*	diurnal	Shrikes	1	SCA
long-billed curlew	*Numenius americanus*	nocturnal	Shorebirds	1	SCA
Mexican free-tailed bat	*Tadarida brasiliensis*	nocturnal	Bats	1	Powerblock
mourning dove	*Zenaida macroura*	variable	Doves/Pigeons	2	Overhead lines
				1	Powerblock
red-winged blackbird	Agelaius phoeniceus	diurnal	Blackbirds/Orioles	1	Fence
				1	SCA
ruddy duck	*Oxyura jamaicensis*	nocturnal	Waterbirds/Waterfowl	1	Pond

Table D-1. Number of individual detections (those made during standardized carcass searches and incidentally), by species, during summer (June 01 – August 30) 2015 at the Genesis Solar Energy Project, Riverside County, California. SCA = Solar collector trough.

Common Name	Scientific Name	Migration Behavior*	Guild	Count	Project Component
snowy egret	*Egretta thula*	nocturnal	Waterbirds/Waterfowl	1	Powerblock
spotted sandpiper	*Actitis macularia*	both	Shorebirds	1	SCA
Townsend's warbler	*Setophaga townsendi*	unresolved	Warblers	1	Powerblock
tree swallow	*Tachycineta bicolor*	diurnal	Swallows	1	Pond
unidentified bat	-	-	Bats	2	Powerblock
unidentified bird (medium)	-	-	Unidentified Birds	1	Pond
unidentified bird (small)	-	-	Unidentified Birds	1	Fence
				1	Powerblock
				3	SCA
unidentified bird (unknown size)	-	-	Unidentified Birds	1	Fence
				1	Powerblock
				1	SCA
unidentified duck	-	-	Waterbirds/Waterfowl	2	SCA
unidentified sandpiper	-	-	Shorebirds	1	Powerblock
western gull	*Larus occidentalis*	resident	Shorebirds	1	SCA
western kingbird	*Tyrannus verticalis*	diurnal	Flycatchers	1	Other
western sandpiper	*Calidris mauri*	both	Shorebirds	1	Pond
white-winged dove	*Zenaida asiatica*	variable	Doves/Pigeons	2	Powerblock
yellow-billed cuckoo	*Coccyzus americanus*	nocturnal	Cuckoos	1	Powerblock
yellow-headed blackbird	*Xanthocephalus xanthocephalus*	diurnal	Blackbirds/Orioles	1	Pond
yellow warbler	*Setophaga petechia*	nocturnal	Warblers	1	Other
Total				**60**	

* See literature cited for migration behavior references; information for most species was taken from the respective species accounts found in Birds of North America (BNA) Online (http://bna.birds.cornell.edu/bna/); where information on migration behavior was lacking in BNA accounts, Evans and Mellinger (1999), Newton (2008), or Murray (2004) were used.
