MIGRATORY BIRD SPECIAL PURPOSE UTILITY PERMIT - SOLAR

10. LOCATION WHERE AUTHORIZED ACTIVITY MAY BE CONDUCTED
Records Location: 1148 Liebert Road El Centro, CA 92243
Carcasses Collection Location: 11S E 620265 N 3622752
Carcasses Stored: 1601 Drew Road, Unit 16 El Centro, CA 92243

11. CONDITIONS AND AUTHORIZATIONS:

A. GENERAL CONDITIONS SET OUT IN SUBPART D OF 50 CFR 13, AND SPECIFIC CONDITIONS CONTAINED IN FEDERAL REGULATIONS CITED IN BLOCK #2 ABOVE, ARE HEREBY MADE A PART OF THIS PERMIT. ALL ACTIVITIES AUTHORIZED HEREIN MUST BE CARRIED OUT IN ACCORD WITH AND FOR THE PURPOSES DESCRIBED IN THE APPLICATION SUBMITTED. CONTINUED VALIDITY, OR RENEWAL, OF THIS PERMIT IS SUBJECT TO COMPLETE AND TIMELY COMPLIANCE WITH ALL APPLICABLE CONDITIONS, INCLUDING THE FILING OF ALL REQUIRED INFORMATION AND REPORTS.

B. THE VALIDITY OF THIS PERMIT IS ALSO CONDITIONED UPON STRICT OBSERVANCE OF ALL APPLICABLE FOREIGN, STATE, LOCAL, TRIBAL, OR OTHER FEDERAL LAW.

C. VALID FOR USE BY PERMITTEE NAMED ABOVE.

This permit does not supersede any State Requirements. You are responsible for ensuring that you are in compliance with all State laws, including but not limited to California Fish and Game Code 3511 (fully protected species) 3503.5 and 3513. For additional information on State requirements please contact: California Department of Fish and Wildlife, Magdalena Rodriguez, 909-945-3294.

D. **Possession and transport.**

1) You and subpermittees are authorized to handle, collect, transport and temporarily possess carcasses and partial remains of birds protected under the Migratory Bird Treaty Act, **except Bald Eagles and Golden Eagles (Eagles)** and species listed as **Threatened or Endangered** under the U.S Endangered Species Act (see 50 CFR § 17.11), found at the location/property specified in Block 10 for monitoring bird mortality associated with operation of the solar facility. To accurately determine species fatality rates, the monitoring study must include standardized carcass searches, searcher efficiency trials, and carcass removal by scavenger trials. For **Eagles and federally listed Threatened or Endangered Species** you must call a U.S. Fish and Wildlife Service (Service), Office of Law Enforcement (OLE) special agent for instructions and approval before collecting or moving the carcass or its parts. It may be necessary to preserve the carcass or its parts onsite until an agent or other Service or State representative

☒ ADDITIONAL CONDITIONS AND AUTHORIZATIONS ALSO APPLY

12. REPORTING REQUIREMENTS
ANNUAL REPORT DUE: 01/31
You must submit an annual report to your Regional Migratory Bird Permit Office each year, even if you had no activity. Form: www.fws.gov/forms/3-202-17.pdf.

ISSUED BY
Heather Beele

TITLE
MIGRATORY BIRD PERMIT SPECIALIST

DATE
09/11/2014

arrives to collect it. **Your OLE point-of-contact is Resident Agent Erin Dean, email: erin_dean@fws.gov , phone: 310-328-1516**

2) Except for take caused by your infrastructure and operations, you may not collect or disturb and must immediately report to OLE any dead migratory birds that appear to have been poisoned, shot, or otherwise killed or injured as the result of potential criminal activity.

3) With prior approval from your Migratory Bird Permit Office, you are authorized to receive lawfully acquired carcasses and parts to use for standardized carcass searches, searcher efficiency trials, and carcass removal by scavenger trials from federally permitted rehabilitation centers or other lawful sources. You must maintain records of all acquisitions, including source (name of permittee and permit number), species, description (carcass or type of part), date of receipt, and final disposition.

E. **Data Collection.**

Mortality monitoring data should be compiled in the attached Excel spreadsheet and submitted to the Service on a monthly basis until directed differently by permit official. It includes but is not limited to the collection of the following information:

1) All relevant and applicable data associated with each carcass or part collection, or injured bird, should be recorded, including the information below. Required data are designated with an asterisk (*).

   a) discovery date*
   b) collection date*
   c) species*
   d) sex and age (juvenile/adult), if known
   e) condition of bird (alive or dead) *
   f) condition of carcass (entire, partial, scavenged)*
   g) description of carcass (e.g., intact, feather spot, headless, wing sheared, blood in mouth, entanglement)*
   h) interval since last search*
   i) observer*
   j) search method used, including opportunistic discovery of carcasses*
   k) weather conditions at likely time of death, if known*
   l) identifying information for the infrastructure element, e.g. solar panel, evaporation pond, fencing, building
   m) the GPS coordinates in decimal degrees for the location where carcass/part found*
   n) ground distance of carcass from pole, line, panel, or other structure (e.g pond or building)
   o) azimuth of carcass from solar panel or infrastructure (including GPS coordinates in decimal degrees), if known
   p) apparent cause of mortality/injury (collision, electrocution, drowned, other) *
   q) estimated date of mortality or estimate of time since death (e.g., <1 day, 1 day, 2-3 days)*
   r) habitat surrounding carcass (*e.g.*, desert, grassland, rural, urban, cropland, bare ground, tall grass)
   s) information on carcass or injured bird disposition*
   t) any special notes or additional information

2) All carcasses and partial remains that are collected should be digitally photographed, bagged, and labeled with the following information:
   1) date collected
   2) a unique specimen number
   3) the information listed in E(1)(l and m) above
   4) facility name

3) Migratory birds, **other than Eagles and federally listed Threatened or Endangered Species**, may be used for searcher efficiency trials and carcass removal trials AFTER a mortality report has been submitted to Regional Migratory Bird Permit Office per condition H(1)(e) documenting their death, all data collected in condition E(2), and the unique specimen number assigned to that carcass in condition E(3) above.

F. **Injured birds.** Injured migratory birds, including **eagles and federally listed threatened or endangered species,** must be transferred to a federally permitted migratory bird rehabilitator or a licensed veterinarian for care. Rehabilitation and/or veterinary costs are the utility's responsibility. See condition H for reporting instructions.

G. **Take and collection of live, non-injured migratory birds, eggs, or nests is not authorized by this permit.** In addition, this permit does not authorize the take, capture, harassment or disturbance of **eagles or federally listed endangered or threatened species** (see 50 CFR 17.11).

H. **Reporting.**

1) You must report bird injuries and deaths in accordance with the time frames specified below (a-c).

a. You must submit a written report of avian mortality and injury **monthly** to OLE, the Regional Migratory Bird Permit Office (RMBPO), the Ecological Service's Field Office (Field Office) and California Department of Fish and Wildlife (CDFW). Your report must include as much of the data listed in condition E above that is available for each incident. In addition, we request that you voluntarily report bat injury and mortality information.

- OLE SA: Your OLE point-of-contact is Resident Agent Erin Dean, (erin_dean@fws.gov , phone 310-328-1516)
- RMBPO: Heather Beeler (heather_beeler@fws.gov, phone: 916-414-6651)
- Field Office- Palm Springs: Pete Sorensen (pete_Sorensen@fws.gov, phone: 760-431-9440 x293)
- CDFW: Email to Armand Gonzales (Armand.Gonzales@wildlife.ca.gov), and Justin Garcia, (Justin.Garcia@wildlife.ca.gov)

b. In addition to the monthly reports, you must report any **bald eagle or golden eagle or threatened or endangered species** found dead or injured to the OLE and each contact listed in H(1)(a) immediately if possible, but no later than **24 hours after discovery.** Your report must include as much of the information from condition E that is available for each incident. A written mortality or injury report specific to the eagle or listed species must be submitted to all contacts listed in condition H(1)(a), to include the data in condition E, no later than **one week (7 days)** from the date of discovery of the carcass.

A list of Threatened and Endangered species by State may be found in the Service's Threatened and Endangered Species System (TESS) database at: <http://www.fws.gov/endangered>.

c. In the event that you discover 6 or more migratory birds that have been injured or killed within a 24 hour period, you must report the event to RMBPO and the Field Office listed in condition H(1)(a) above immediately if possible, but no later than the **next business day**. This summary must list the number of events by species. Within 14 days of carcass/injury discovery, a written mortality or injury report specific to the incident must be submitted to your FWS contacts, and should include as much of the data in E above as possible. This reporting requirement is intended to inform the Service of events or other variables that may have contributed to the mortality event.

2) You must submit an **Annual Report** of dead and injured birds, **including Eagles and Threatened and Endangered Species**, discovered and/or collected to your Migratory Bird Permit Office by January 31 following each calendar year in which the permit is in effect. Your written annual report is due by 1/31/14. The traditional report form 3-202-17 is available at <http://www.fws.gov/forms/3-202-17.pdf>. Please submit a Special Purpose

Utility Excel Data Sheet we provided in lieu of using form 3-202-17. All of the information requested on the 3-202-17 form, including the signed certification statement, must be included.

I. **Disposition of Carcasses and Parts.**

1) In accordance with Condition D(1) above, the Service will advise you on disposition of **Eagles and federally listed Threatened or Endangered Species** specimens. The special agent will advise if they will recover an eagle carcass or if you need to ship the carcass to the Service. With PRIOR written authorization from an OLE special agent, you may contact the U.S. Fish and Wildlife Service, National Eagle and Wildlife Property Repository (NER) at (303) 287-2110 for shipping instructions. The written authorization from the special agent must accompany the Eagle if it is shipped to the NER. Disposition must be reported in your annual report to your migratory bird permit issuing office.

2) Unless otherwise specified in this permit, **Migratory Bird carcasses** and parts (**other than Eagles and federally listed Threatened or Endangered Species**) collected during the calendar year (ending Dec 31) that have been documented in your records must be stored in the freezer at the facilities at the location specified in Block 10 **until January 15** of the following year in which they were collected. Unless otherwise specified by your migratory bird permit issuing office or OLE, after **January 15** and after your annual report has been submitted to the migratory bird permit issuing office (due January 31), carcasses and parts may be:

(a) used for searcher efficiency and scavenger removal trials; provided carcasses used in trials have been reported to the Service prior to use as outlined in Condition F and I(1)(c) above;

(b) turned over to the State wildlife agency for official purposes, or,

(c) donated to a public scientific or educational institution or to an individual or entity authorized by Federal permit to acquire and possess migratory bird specimens.

After all permit requirements have been met, carcasses and parts (**except Eagles and federally listed Threatened or Endangered species**) that you do not transfer to another authorized party must be disposed of by burial or incineration.

J. **Renewal**. In addition to an updated monitoring protocol, any request for renewal of this permit must include information on the fatality rates of affected species or fatality patterns, analysis of those rates/patterns, whether any adjustments or measures were taken to avoid or minimize mortalities, and if so, any preliminary results of those modifications.

K. **Subpermittees.** Any person who is employed by or under contract to the permittee for the activities specified in this permit, or is otherwise designated as a subpermittee in writing by the permittee may exercise the authority of this permit.

L. **Standard Conditions.** You and any subpermittees must comply with the attached **Standard Conditions for Migratory Bird Special Purpose Utility Salvage Permits. These standard conditions are a continuation of your permit conditions and must remain with your permit.**

This permit does not supersede any State Requirements. You are responsible for ensuring that you are in compliance with all State laws, including but not limited to California Fish and Game Code 3511 (fully protected species) 3503.5 and 3513. For additional information on State requirements please contact: California Department of Fish and Wildlife, Deborah Hawk, 760-872-1126.

This permit does not, nor shall it be construed to, authorize lethal take or injury of migratory birds or limit or preclude the U.S. Fish and Wildlife Service from exercising its authority under any law, statute, or regulation, or from taking enforcement action against any individual, company, or agency. This permit is not intended to relieve any individual, company, or agency of its obligations to comply with any applicable Federal, State, Tribal, or local law, statute, or regulation.

This permit may be amended at any time in response to changes in national guidance or take reported.

Attachment A. Standard Conditions

Migratory Bird Special Purpose
Utility Salvage Permits
50 CFR 21.27

All of the provisions and conditions of the governing regulations at 50 CFR part 13 and 50 CFR 21.27 are conditions of your permit. Failure to comply with the conditions of your permit could be cause for suspension of the permit. The standard conditions below are a continuation of your permit conditions and must remain with your permit. If you have any questions regarding these conditions, refer to the regulations or, if necessary, contact your migratory bird permit issuing office. For copies of the regulations and forms, or to obtain contact information for your issuing office, visit: http://www.fws.gov/migratorybirds/mbpermits.html.

1. **Personal use.** This permit does not authorize personal use of any migratory birds, parts, nests or eggs salvaged, transported, or temporarily possessed under the authority of this permit.

2. **Banded Birds** (carcasses collected and injured birds) must be reported to the U.S. Geological Survey Bird Banding Laboratory at 1-800-327-2263 or *http://www.reportband.gov*. Information provided must include, as accurately as possible, species of bird, band number, date recovered, recovery location, and name and contact information of the person who recovered the carcass or bird.

3. **Subpermittees.** A subpermittee is an individual to whom you have provided written authorization to conduct some or all of the permitted activities in your absence. Subpermittees must be at least 18 years of age. As the permittee, you are legally responsible for ensuring that anyone conducting activities under your permit is adequately trained and adheres to the terms of your permit. You are responsible for maintaining current records of who you have designated as a subpermittee, including copies of designation letters you have provided.

4. **Carrying your permit.** You and any subpermittees must carry a legible copy of this permit and display it upon request of any duly authorized federal, state or tribal officer whenever exercising its authority. Subpermittees must also carry your written subpermittee designation letter.

5. **Records.** You must maintain complete and accurate records of the activities conducted and the data collected under this permit. You must keep all required records and collected wildlife parts relating to permitted activities at the location you identified in writing to the migratory bird permit issuing office. (50 CFR 13.46 and 21.27)

6. **Site inspections.** Acceptance of this permit authorizes the Director's agent to enter the utility property at any reasonable hour as necessary to inspect the wildlife, records, facilities, property, and associated infrastructure for wildlife impacted by the utility, and for compliance with the terms of this permit and governing regulations. (50 CFR 13.47)

7. **Applicable laws.** You may not conduct the activities authorized by this permit if doing so would violate the laws of the applicable State, county, municipal or tribal government or any other applicable law.

8. **Other permissions.** This permit does not authorize salvage of specimens on Federal, State, tribal, or other public or private property without additional prior written permits or permission from the agency/landowner/custodian.

CC: Daniel Steward (BLM), Sharon Tyson (BLM), Pete Sorenson (USFWS),
and Patricia Valenzuela (Imperial County)

Date: 11/22/2011

Re: Imperial Solar Energy Center (ISEC) South – Burrowing Owl (BUOW) Mortality

---

On November 20, 2011 UltraSystems biologists conducted another 30-day Preconstruction Burrowing Owl Survey at the Imperial Solar Energy Center South (ISEC South) project, due to construction delays. A second preconstruction survey is necessary to meet 30-day permit requirements. This preconstruction survey was completed by UltraSystems biologists James Castle (Designated Biologist) and Charlene Burge (biological Monitor), in coordination with Marie Barrett (biological specialist) of Barrett Biological Services.

During the second round of pre-construction surveys (11/20/2011), one BUOW mortality was observed by the biologists on the northern edge of the project site. The mortality was located along a minor agricultural road. No evidence except feathers were present (See photo below). No determination as to cause of mortality was made by the biologists. The adjacent agricultural fields have been recently cultivated, where field equipment had turned up the edges into an unlined, shallow drainage ditch.

It should be noted that **no mobilization** has occurred on the ISEC South project site; therefore, **no equipment** is onsite.

An amended letter report for this most recent BUOW Preconstruction Survey is forthcoming, and will be sent to the agencies and Imperial County as soon as possible.

In addition to the wildlife species previously reported during the first 30-day Preconstruction Survey, four new raptor species, two songbird species, one fisher, and two game bird species were observed by the biologists, during this second survey.

The species include: Sharp-shinned Hawk, Peregrine Falcon, Ferruginous Hawk, Osprey, Verdin, King Fisher, Savannah Sparrow, Snow Goose and Canadian Goose.

Should you have any questions, please contact me at (949) 788-4900.

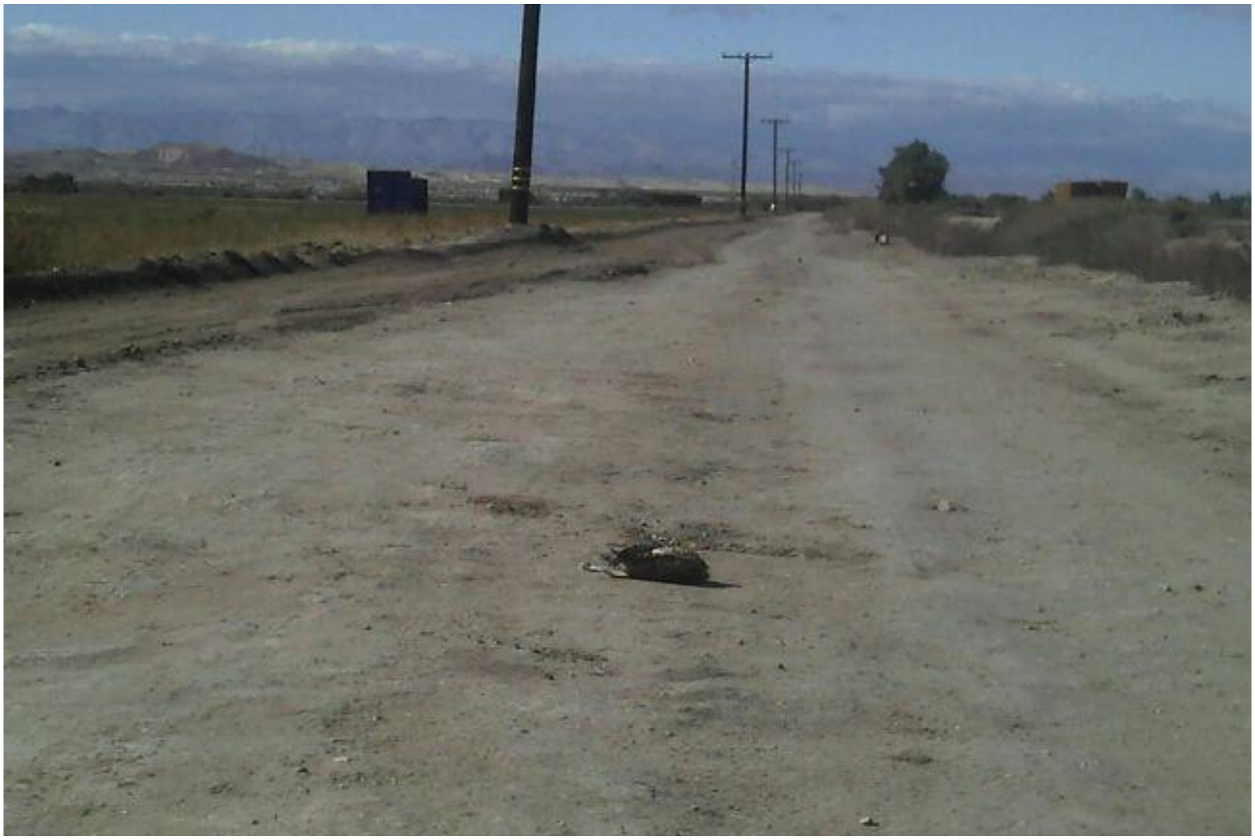
Re: Imperial Solar Energy Center (ISEC) South – Burrowing Owl (BUOW) Mortality

On November 27, 2011 the project Designated Biologist, Jim Castle (UltraSystems) was notified of a BUOW mortality at the ISEC South project by site security personnel. The mortality was discovered along a minor agricultural road. An assessment was completed by UltraSystems' biologist Michael Crouse (biological monitor) that included locating the discovery using GPS coordinates, and taking photographs. No determination as to cause of mortality could be ascertained by Mr. Crouse.

It should be noted that construction at ISEC South has not begun. Mobilization is expected to occur on or about December 6, 2011.

Should you have any questions, please contact me at (949) 788-4900.

BUOW Mortality – observed on November 27, 2011.



GPS Coordinates: 32 ° N 39.868 minutes, 115 ° W 39.424 minutes (road along central agricultural area).

ACKNOWLEDGEMENTS

This project was funded by the California Energy Commission's Public Interest Energy Research (PIER) Program under Award No. PIR-08-028, with matching funds provided by the U.S. Fish and Wildlife Service under Grant # F11AP00016/13410BG006. NextEra Energy Resources, LLC, provided substantial in-kind match support in the form of raw field survey datasets with accompanying avian and bat work study plans and monitoring reports, in-kind labor, extensive site access, and bird and bat carcasses. Acciona Energy North America Corporation also provided substantial in-kind match support in the form of raw field survey datasets with accompanying avian and bat work study plans and monitoring reports, in-kind labor, and site access. The Michigan Department of Community Health, the Texas Christian University Department of Biology, and the Idaho State Department of Agriculture provided additional bat carcasses. Cardno ENTRIX provided additional in-kind communications support, and the Altamont Pass Wind Resource Area Scientific Review Committee provided feedback on the research team's study design.

The authors thank Energy Commission staff Linda Spiegel for overseeing the project and Joe O'Hagan and John Mathias for managing it, as well as U.S. Fish and Wildlife Service staff Mark Miller, Jim Michaels, Mark Ostwald, Ken Berg, Steve Desimone, and Pamela Kosonen for the additional resources to expand this research. In addition to the primary authors listed, numerous staff and contractors of the California Wind Energy Association contributed to the project, including Executive Director Nancy Rader, Project Manager Heather Rhoads-Weaver, Editor Susan Savitt Schwartz, Siting Policy Director Ashley Richmond, and Assistant Project Managers Chris Amado and Alma Correa-Holmes. Additional EcoStat staff contributors included Song Qian, Sandra Menzel, Brandi Gartland, Casey Greenstein, Achille Clendenning, Andrea Torres, Jolie Hendrix, Felix Ratcliff, Derek Jansen, and Natalie Archambault. Additional Normandeau staff contributors included Crissy Sutter, Christian Newman, Alexis Hampton, and Jenny Carter.

The authors are grateful to their Project Advisory Committee members who spent a significant amount of time providing advice and reviewing documents: Dr. Eric Smith of Virginia Tech, Dick Anderson, formerly with the California Energy Commission, Bronwyn Hogan of U.S. Fish and Wildlife Service, Dr. John Hayes of the University of Florida, Kevin Martin of Terra-Gen Power, and Renee Culver of NextEra Energy Resources. The authors also appreciate the thoughtful review and comments from their peer reviewers: Dr. Lyman McDonald of Western EcoSystems Technology, Inc., and Dr. Amanda Hale of Texas Christian University.

PREFACE

The California Energy Commission Public Interest Energy Research (PIER) Program supports public interest energy research and development that will help improve the quality of life in California by bringing environmentally safe, affordable, and reliable energy services and products to the marketplace.

The PIER Program conducts public interest research, development, and demonstration (RD&D) projects to benefit California.

The PIER Program strives to conduct the most promising public interest energy research by partnering with RD&D entities, including individuals, businesses, utilities, and public or private research institutions.

PIER funding efforts are focused on the following RD&D program areas:

- Buildings End-Use Energy Efficiency
- Energy Innovations Small Grants
- Energy-Related Environmental Research
- Energy Systems Integration
- Environmentally Preferred Advanced Generation
- Industrial/Agricultural/Water End-Use Energy Efficiency
- Renewable Energy Technologies
- Transportation

Improving Methods for Estimating Fatality of Birds and Bats at Wind Energy Facilities is the final report for the Energy Commission, Project Award Number PIR-08-028, conducted by California Wind Energy Association (CalWEA). The information from this project contributes to PIER's Energy-Related Environmental Research Program.

For more information about the PIER Program, please visit the Energy Commission's website at www.energy.ca.gov/research/ or contact the Energy Commission at 916-654-4878.

ABSTRACT

The California Wind Energy Association (CalWEA) evaluated the procedures in the *California Guidelines for Reducing Impacts to Birds and Bats from Wind Energy Development* (the Guidelines) for estimating fatality of birds and bats associated with wind energy facilities. The research sought to improve the accuracy of methods for estimating the number of bird and bat fatalities by evaluating the effect of time dependency on the probability of scavenging and removal of bird and bat carcasses (carcass persistence) and detection by searchers (searcher proficiency).

Researchers used data collected from the Altamont Pass Wind Resource Area from January 7 to April 30, 2011, to calculate traditional carcass persistence and searcher proficiency functions and to create new functions in which searcher proficiency and carcass persistence are modeled as a function of time and carcass age. This study is the first to document quantitatively that searcher proficiency and carcass persistence are time-based processes. The report offers lessons and implications for experimental designs and the field monitoring recommendations provided in the Guidelines.

The study also investigated the fatality estimation equation provided in the Guidelines and three other prominent equations from the literature that are used to adjust fatality observations for searcher proficiency and carcass persistence. The report examines both the common and equation-specific assumptions inherent in these fatality estimators, evaluates them in light of data from the field experiment, and finds that each of the fatality estimation equations can result in positive or negative bias, depending on the length of search interval relative to carcass persistence time. A new equation incorporating carcass persistence from one search interval to the next is proposed. This project will help reduce conflict in the siting process and make sound wind project permitting decisions easier by improving the accuracy of fatality estimates and the ability to accurately compare them with those from other wind facilities.

Keywords: Estimation methods, birds and bats, wind energy facilities, time dependence, searcher proficiency, carcass persistence, monitoring design, equations, statistical bias

TABLE OF CONTENTS

EXECUTIVE SUMMARY

Introduction

Wind energy holds great promise as a clean, renewable energy resource, provided that siting and development can reasonably avoid or reduce impacts on already stressed wildlife resources. In 2007, the California Energy Commission and California Department of Fish and Game released *California Guidelines for Reducing Impacts to Birds and Bats from Wind Energy Development* (the Guidelines) to provide recommended procedures for assessing and minimizing impacts from wind energy development on birds and bats. The Guidelines provide an equation, attributed to Dr. Kenneth Pollock of North Carolina State University, that estimates the true number of fatalities at the wind facility from the number of bird or bat carcasses visually observed during a monitoring survey. The equation corrects for the inability of a searcher to locate all carcasses on the survey plot at the time of observation (searcher proficiency), and for the probability of removal by scavengers (such as crows and coyotes) or other processes before the time of observation (carcass persistence).

The California Wind Energy Association (CalWEA) rigorously evaluated the methods and procedures proposed by the Energy Commission for estimating the true number of fatalities of birds and bats (including the equation in the Guidelines) associated with collisions with wind turbines in California.

Purpose

This project sought to improve the accuracy of methods for estimating the number of bird and bat fatalities at wind energy facilities.

This report describes the sites selected for study, the experimental design for evaluating and testing approaches for estimating the true bird and bat fatalities at a wind facility from observational evidence of collision mortality, and the data collection procedures. This report also looks at the fatality estimation equation provided in the Guidelines and at three other prominent equations from the literature that are used to adjust mortality observations (hereafter referred to by their respective authors: Erickson & Johnson, Shoenfeld, and Huso). It examines the assumptions common to all four estimation equations as well as those assumptions specific to each. It then evaluates the validity of the assumptions with data from the field experiment, given various field conditions, and fatality observation parameters. Based on the field study findings and a thorough analysis of assumptions underlying the published equations, this report offers lessons and implications for experimental designs and the field monitoring recommendations provided in the Guidelines.

Objectives and Findings

The project was designed to meet the following objectives:

- Refine and test experimental designs, under representative actual field conditions, that accurately generate site-specific data for estimating survey error rates.

- Rigorously evaluate the ability of various equations to accurately estimate fatalities of birds and bats at a variety of wind energy facilities within California.

The Field Study: Design and Findings

CalWEA rigorously designed and implemented a field survey to collect site-specific data under a variety of environmental conditions. Researchers obtained bird and bat carcasses from various labs and agencies and placed them at selected locations within the Altamont Pass Wind Resource Area near Livermore, California. Over periods of up to 60 days, independent and experienced biologists without prior knowledge of carcass placements searched strings of turbines weekly and recorded the location of marked bird and bat carcasses that project field managers had placed in the study area, as well as carcasses not associated with the study. Project field managers recorded the movement and removal of trial bird and bat carcasses roughly every three days during the study when trial birds and bats were on the ground, so that the true number and location of the trial carcasses were known. Consistent with current practice, it was assumed that carcass persistence and detection rates for marked carcasses placed at the site are representative of rates for bird and bat fatalities otherwise occurring at the wind energy facility.

Researchers used data generated by the field study to calculate traditional carcass persistence and searcher proficiency functions and to create new functions in which both carcass persistence and proficiency are modeled as a function of time and carcass age. Of the 104 small bird carcasses placed in the field, 32 unique carcasses (31 percent) were found over the course of 223 search opportunities (number of placed carcasses times the number of searches in which a trial carcass was present). However, field biologists detected carcasses in only 17 percent of all small bird search opportunities. Of the 78 bat carcasses placed, 15 unique bat carcasses (19 percent) were found over the course of 248 search opportunities, but only 8.1 percent of search opportunities yielded detections. All six of the large birds were detected, with 68 percent of 31 search opportunities yielding detections.

Researchers examined the rate of carcass removal by scavengers in strings (a group or row of adjacent wind turbines), blocks of strings with similar ecological conditions, and the entire study area. They also examined relationships between carcass persistence and key variables. The carcass removal rate followed a Weibull distribution, with the highest removal rates early in the trial. Scavengers removed most small birds and bat carcasses within six weeks of placement. The data also show that it was common for a carcass to persist into subsequent search intervals beyond the interval during which it was deposited (called "bleed-through").

The study found both searcher proficiency and carcass persistence to depend on time. Other key findings with implications for selection of fatality-estimating equations and equation input variables include:

- Carcass persistence fits better with a Weibull distribution, where the attractiveness of a carcass to scavengers declines as it ages, than with an exponential distribution where fresh and old carcasses are equally likely to be attractive to scavengers.
- Vegetation height affects searcher proficiency. Therefore, when creating a survey design, researchers may want to consider random selection of turbines within blocks. The study found that topographical (for example, slope) and meteorological variables (for example, precipitation) were not correlated with mortality at the study site. They may be important predictors at other sites, however.
- Searcher proficiency was considerably lower for bats than for small birds during the study, pointing to the need for extensive long-term searcher proficiency trials for bats to ascertain if this holds true at other sites.
- Small bird carcasses are removed by scavengers more quickly than bat carcasses. This finding supports the need for long-term carcass persistence trials for both small birds and bats.

Evaluation of the Fatality Estimation Equations

As proposed, the second part of this project was to use the field study data to test how accurately the Pollock equation recommended in the Guidelines and the three other prominent equations estimate the true number of fatalities from observed fatalities. Because the equations assume that fatalities occur at random times, while this study involved placing all carcasses at the beginning of each experimental time block, a direct “test” of the equations using the study data was not appropriate. Instead, the authors analyzed the estimating equations (“estimators”) mathematically and tested the validity of their common and individual assumptions against the findings from the field study.

Key findings from this analysis were that:

- All of the four traditional fatality estimation equations examined assume constant searcher proficiency, rather than the observed condition that searcher proficiency is a function of time, as carcasses age. The inconsistent ability to detect a bird or bat over time can greatly affect the expected accuracy of resulting mortality estimates.
- Three of the equations examined (Erickson & Johnson, Shoenfeld, and Huso) assume an exponential distribution), whereas a Weibull statistical distribution fits the data best.
- Current estimators either assume that “bleed-through”– whether carcasses not removed during one search interval are considered “discoverable” during later searches – occurs all of the time or none of the time. Incorrect bleed-through assumptions can distort estimates.
- In the general case, and for exponential removal, the equations will generate mortality of the following order from lowest to highest: Erickson & Johnson < Shoenfeld < Pollock≤

Huso. When choosing a single equation, investigators should keep the expected rank order in mind.

- The degree of systematic error or "bias" among the equations is a function of many issues, but in all cases, it is a function of the inherent assumptions underlying the equation characteristics. Even when biased, if search intervals are *long* relative to mean persistence times, all four estimators give about the same answers. But if search intervals are *short* relative to mean persistence times, large differences among the equations are possible. In fact, with the condition of short interval relative to mean carcass persistence, the results of the equations could differ by a factor of 3 or 4.
- Even correcting for the biases, the relationship of the results of the estimators to true mortality is unknown. However, if the assumptions in the equations are wrong (that is, where exponential distributions and constant searcher proficiencies have been assumed), then the results of the equations could differ significantly from actual mortality.
- Short search intervals increase the chance of bias:
  (a) Short intervals do not allow the system to reach equilibrium, which is inconsistent with the Erickson & Johnson equation. Erickson & Johnson assume the number of carcasses remains relatively constant over the long-term.
  (b) The Huso and Pollock equations assume zero percent bleed-through; therefore, bias will occur if true bleed-through is greater than zero.
  (c) Shoenfeld assumes 100 percent bleed-through; therefore, bias will occur if true bleed-through is less than 100 percent.

- The new partially periodic equation proposed in this report allows for the estimation of a site-specific bleed-through rate. Paired with new field sampling procedures to generate time-dependent carcass persistence and searcher proficiency probabilities, this new equation will produce unbiased results using either short or long search intervals.

Conclusions and Recommendations

CalWEA's study provides new insights that could enhance the existing methods and procedures found in the Guidelines and other pre- and post-construction fatality monitoring guidelines used in the United States and internationally. Four major implications of this work and the corresponding recommendations are outlined here.

(1) Traditional fatality estimators do not account for time-dependence of carcass persistence and searcher proficiency, or for "bleed-through."

Recommendation: Use the proposed new Partial Periodic Estimator and integrated detection probability trial method (proposed in Appendices A and B, respectively).

(2) Traditional estimators can have high degrees of bias depending on the search interval, mean carcass persistence, and bleed-through rate of the field data collected.

Recommendation: Do not use traditional estimators in conditions that produce levels of bias that are unacceptable for the intended purpose. Caution is particularly warranted where short search intervals have been used.

(3) Use of traditional estimators has resulted in an unknown degree of bias in the literature.

Recommendation: Carefully consider the value of metrics like "industry average" before applying them in policy or project-specific decisions.

(4) Previously generated fatality estimates used for project evaluation or broader purposes could be recalculated using the proposed new Partial Periodic Estimator, provided the key input variables (search interval, mean carcass persistence, and so forth) can be collected from the original studies and reasonable assumptions made about searcher proficiency probability distributions and bleed-through values.

Recommendation: Going forward, use a standardized approach to generate unbiased, project-specific results that may be compared with each other, and to generate meaningful and unbiased industry averages and totals.

This project will help reduce conflict in the siting process and make sound wind project permitting decisions easier by:

- Providing guidance on methods for generating observer bias and carcass removal rates and reducing ambiguity in recommended avian study methods.
- Exploring time-dependent relationships, including observer bias and carcass removal.
- Providing guidance leading to improved field procedures for mortality monitoring and improving efficiency and efficacy of surveys.
- Enabling better forecasting of anticipated mortality at wind facilities based on site characteristics.

CHAPTER 1: Research Plan

Statement of Need

California pioneered large-scale wind energy development beginning in the 1970s. As a clean, renewable energy resource, wind energy holds great promise provided that it can be sited and developed in such a way as to reasonably avoid and (if necessary) mitigate impacts on already stressed wildlife resources. To this end, wind energy and wildlife stakeholders have collaborated to survey avian/bat activity and study the impacts of wind project operations, and policymakers have incorporated research protocols into the permitting process.

In 2007, the California Energy Commission (Energy Commission) and California Department of Fish and Game released *California Guidelines for Reducing Impacts to Birds and Bats from Wind Energy Development* (the Guidelines) to provide recommended protocols for assessing and minimizing impacts from wind energy development to birds and bats. The Guidelines recommend protocols for assessing, evaluating, and determining the effects of wind projects on birds and bats, and also recommend impact avoidance, minimization, and mitigation measures. In addition, the Guidelines provide an equation, suggested by Dr. Kenneth H. Pollock (personal communication, 2012), that can be used to adjust the number of bird or bat carcasses that are visually observed during an environmental monitoring survey of a wind facility, in an attempt to estimate the true fatalities at the wind facility. The equation, one of four analyzed in this report, adjusts for the inability of a searcher to locate all carcasses on the survey plot at the time of observation, and for the probability of removal by scavengers or other processes before the time of observation.

The California Wind Energy Association (CalWEA) received funding from the Energy Commission to rigorously evaluate the equations and associated procedures and studies recommended in the Guidelines for estimating fatalities of birds and bats associated with collisions with wind turbines in California. Information gathered from this study will apply to wind development projects in California, and the fundamental principles evaluated and discovered in this project may apply to wind development in other parts of the United States and internationally.

CalWEA's study provides new insights leading to improvements in the methods and procedures for estimating fatalities at wind facilities. This report offers recommendations on methods, including computations and data requirements, for estimating the true bird and bat fatalities at wind facilities. This section of the report details the goals of CalWEA's project and reviews statistical and ecological considerations in the project design.

Study Goal and Objectives

The overall goal of this project was to conduct research to improve the accuracy of methods for estimating the number of bird and bat fatalities at wind energy facilities. The project was designed to meet the following objectives:

1. Empirically test and calculate the influence of carcass removal and searcher proficiency under representative actual field conditions.

2. Mathematically evaluate the inherent characteristics and assumptions of existing equations to accurately estimate fatalities of birds and bats at representative wind energy facilities within California.

The study generated information to enable the evaluation of existing fatality estimation methods and the development of advanced models.

To meet the first project objective, CalWEA implemented a rigorously designed field survey at a wind facility within the Altamont Pass Wind Resources Area (APWRA) near Livermore, California. Site-specific data were collected under a variety of environmental conditions. Simply stated, birds and bats were placed at selected locations within the site. The implicit assumption in this approach is that marked birds and bats are representative of birds and bats killed at the wind facility. Over periods of up to 60 days, "blind" independent and experienced biologists without prior knowledge of carcass placements searched turbine strings and recorded the location of both marked bird and bat carcasses that project field managers had placed in the study area as well as carcasses not associated with the study.

Data generated during the experiment were collected and stored in a quality assured data set. The research team then analyzed the resulting data and evaluated the relationships among the number of found birds, bats, and environmental conditions over time. A description of the available statistical models evaluated in this study is found in the following discussion. The models and methods were evaluated for their inherent ability to accurately estimate the true number of bird and bat carcasses.

Once the study team evaluated the data, tested existing models and created new models, the team developed general guidance for (1) generating site-specific data used to parameterize equations, (2) selecting existing or new equations based on site-specific conditions, and (3) interpreting the results generated by the statistical methods.

This project provides insights into several other issues that are important to risk assessments of wind facilities. Specifically, this project generates information that can be used to:

- Evaluate existing fatality estimation methods.
- Test and evaluate the shape of carcass persistence curves (those not removed by scavenging, weather and other processes) under a variety of environmental conditions, as represented during the January – April grass height and weather conditions at the Altamont.
- Evaluate the effect of time-dependency on the probability of bird and bat carcass persistence and on the probability of detection by searchers (searcher proficiency).
- Develop recommendations for advanced models that link observational data with measurements of ecological conditions.

Success Measures

This project succeeded by achieving the following goals.

- Evaluation of the existing fatality equations provides practitioners information useful for choosing an estimating equation, and an understanding of the advantages and disadvantages of various equations with differing survey designs.
- Data generated from the project are of such quality that guidance for implementing site-specific studies leading to effective fatality adjustment procedures can be developed.
- Peer-reviewed publications can be generated that enhance the existing state of the science.
- Effective communication of the project findings was undertaken.
- Observational data at the planned wind turbine strings were obtained in a cost-effective manner within the timeframe of the project.

The following narrative discusses the statistical and ecological issues that influenced the design of the study, and presents the experimental design.

Statistical Considerations in the Experimental Design

Although standardized long-term monitoring procedures are available in the literature, there is currently no standard operating procedure for generating and evaluating data used to estimate fatalities at wind project sites. Statistical simulations of this issue have been conducted (*e.g.*, Huso 2010). In practice within the industry, searcher bias and scavenger removal studies are generally implemented in conjunction with long-term monitoring studies. However, based on an informal review and the experience of the authors of this report, there is little consistency in survey design and analysis of the resulting data among agencies, industry, or their consultants. Searcher bias studies are typically implemented independently from studies of removal by scavenging and other processes, and the study timeframes generally differ. In some cases, searcher bias studies are conducted once under site-specific conditions, and are not repeated during the course of a year. Carcass persistence studies are generally implemented over a few days to several weeks; however, the study time period is not standardized within the industry.

For both study types, fresh (or sometimes frozen) carcasses of various sizes are placed on an experimental plot at the beginning of the experiment. During searcher bias experiments, searchers search plots where trial carcasses have been placed and record the number of carcasses found. The searcher proficiency rate is then calculated and recorded. During scavenger removal studies, the known locations of the carcasses are observed frequently and removals are noted. Analysis of the resulting data generally provides a simple constant representing the probability that a bird or bat is removed by scavenging and other processes, although some time-series models resulting in the probability of scavenger removal as a function of time have been proposed (Smallwood 2007).

There is little consistency across searcher bias and scavenger removal studies in terms of plot area, number of carcasses used, carcass species, number of searchers tested, size of carcasses used, habitat considerations, or study timeframes. The relationship between searcher proficiency and carcass persistence is not evaluated. Finally, the monitoring techniques employed during the searcher studies (*e.g.*, random searches, transect searches, search interval, etc.) are sometimes inconsistent with those employed during long-term site-specific monitoring studies at operating wind turbine facilities.

A number of equations are found in the peer-reviewed literature for adjusting the observable fatality counts to estimate the true number of killed birds and bats. This report reviews selected equations found in the literature, compares the properties of each of the estimators, and provides recommendations for improving their accuracy. The equations were chosen based on a review of literature that indicated that these equations have been commonly used within the wind industry. The equations are heavily cited in past and current peer-reviewed literature.

Ecological Considerations in the Experimental Design

The following discussion reviews the importance of key ecological variables in the estimation of survey error. In addition, key procedural and other experimental design variables are described.

Ecological Variation

Ecological variation associated with specific wind energy development sites within the State of California was an important consideration in the design of the experiments. Variation in habitat condition was considered a key variable affecting the change in survey error among locations. Variation in vegetation type and density, scavenger species and associated activity levels, climate conditions, geographic conditions associated with turbine placement, and a host of other site-specific variables also could influence the overall survey error rate for a specific site.

Size of the Carcasses

Carcass size is a key variable that influences both searcher detection proficiency and carcass persistence. Generally, larger birds (*e.g.*, golden eagles) are easier to see and are considered to have smaller survey error rates than smaller birds (or bats). The smaller birds (or bats) are more difficult to see over large distances, and may be more easily covered by vegetation. Also, smaller carcasses are more subject to removal by scavengers (see references found at http://www.altamontsrc.org/alt_rl.php).

The study's experiments were focused on smaller birds and bats based on the assumption that those carcasses are harder to find and therefore will have higher error rates. Carcasses representing similar size classes were used in the experiments.

Scavenger Type and Density

The activity level of scavengers at the test site(s) was an important consideration in the selection of the locations in which the experiments were conducted. Types of scavengers noted at the Altamont include birds (*e.g.*, ravens, crows, golden eagles, turkey vultures), and mammals (*e.g.*, foxes, coyotes, bobcats, raccoons, skunks, opossums, shrews, deer mice). Although scavenger activity was not monitored, the large number of scavenger species at the Altamont is expected to be representative of wind facilities across the United States.

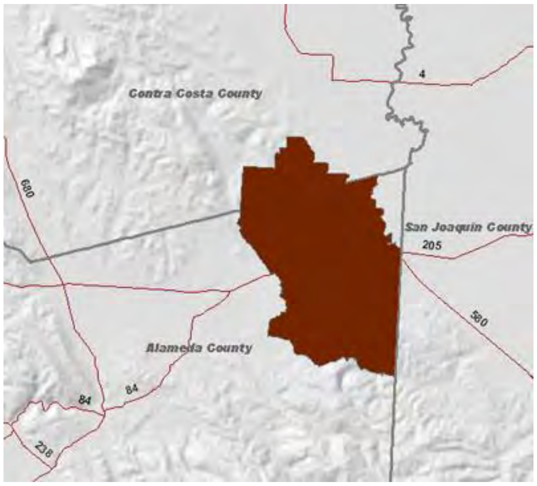
CHAPTER 2: Field Sampling Procedures and Results

As discussed in detail below, field sampling involved marking bird and bat carcasses, placing them randomly at turbine strings at an operating wind farm, and collecting information on carcass persistence and searcher proficiency. Turbine strings were selected to represent varied environmental conditions, including vegetation type and height and slope.

Description of Study Area

The field study was conducted in NextEra Energy's Contra Costa County portion of the Altamont Pass Wind Resource Area (APWRA), which is located in north-central California approximately 56 miles (908 kilometers) east of San Francisco (Figure 1). Steady winds of 15–30 miles (25–45 kilometers) per hour blow across the APWRA during the mid-afternoon and evening periods between April and September, when 70–80 percent of the wind turbine power is generated in the APWRA (Smallwood and Thelander 2004).

Figure 1: Location of Altamont Pass Wind Resource Area (APWRA)



Source: NextEra Energy Resources

The Altamont landscape consists of rolling hills ranging mostly between 150 and 300 feet (61-91 m) in elevation above sea level. Permits have been granted for a total of 5,400 wind turbines in the APWRA, rated at a capacity of approximately 580 megawatts (MW), distributed over 50,000 acres (150 square kilometers) of rolling grassland hills and valleys. Turbines are arrayed along ridgelines and other geographic features. The actual number of turbines available at any one time for power generation is thought to range from 4,500 to 5,000.

The APWRA supports a broad diversity of resident, migratory, and wintering bird species that regularly move through the wind turbine area (Orloff and Flannery 1996). Diurnal raptors (eagles and hawks), in particular, use the prevailing winds and updrafts for soaring and gliding during daily movement, foraging, and migration. Multiple studies of avian fatality at the APWRA show that golden eagles, red-tailed hawks, American kestrels, burrowing owls, barn owls, and a diverse mix of small birds and non-raptor species have been killed in turbine-related incidents (Howell and DiDonato 1991; Orloff and Flannery 1996; Howell 1997; Smallwood and Thelander 2004). All native species are protected by either federal and state wildlife legislation or both.

From an experimental perspective, the geographical unit of interest at the Altamont is a turbine string (a line of turbines). More than 400 of these strings have been monitored on a regular basis. The monitored strings are located over the extent of the APWRA, and therefore cover a variety of vegetation types and topological conditions.[1] Figure 2 shows the heterogeneity of the habitats around the field study wind turbines and strings.

Overview of Field Sampling Procedures

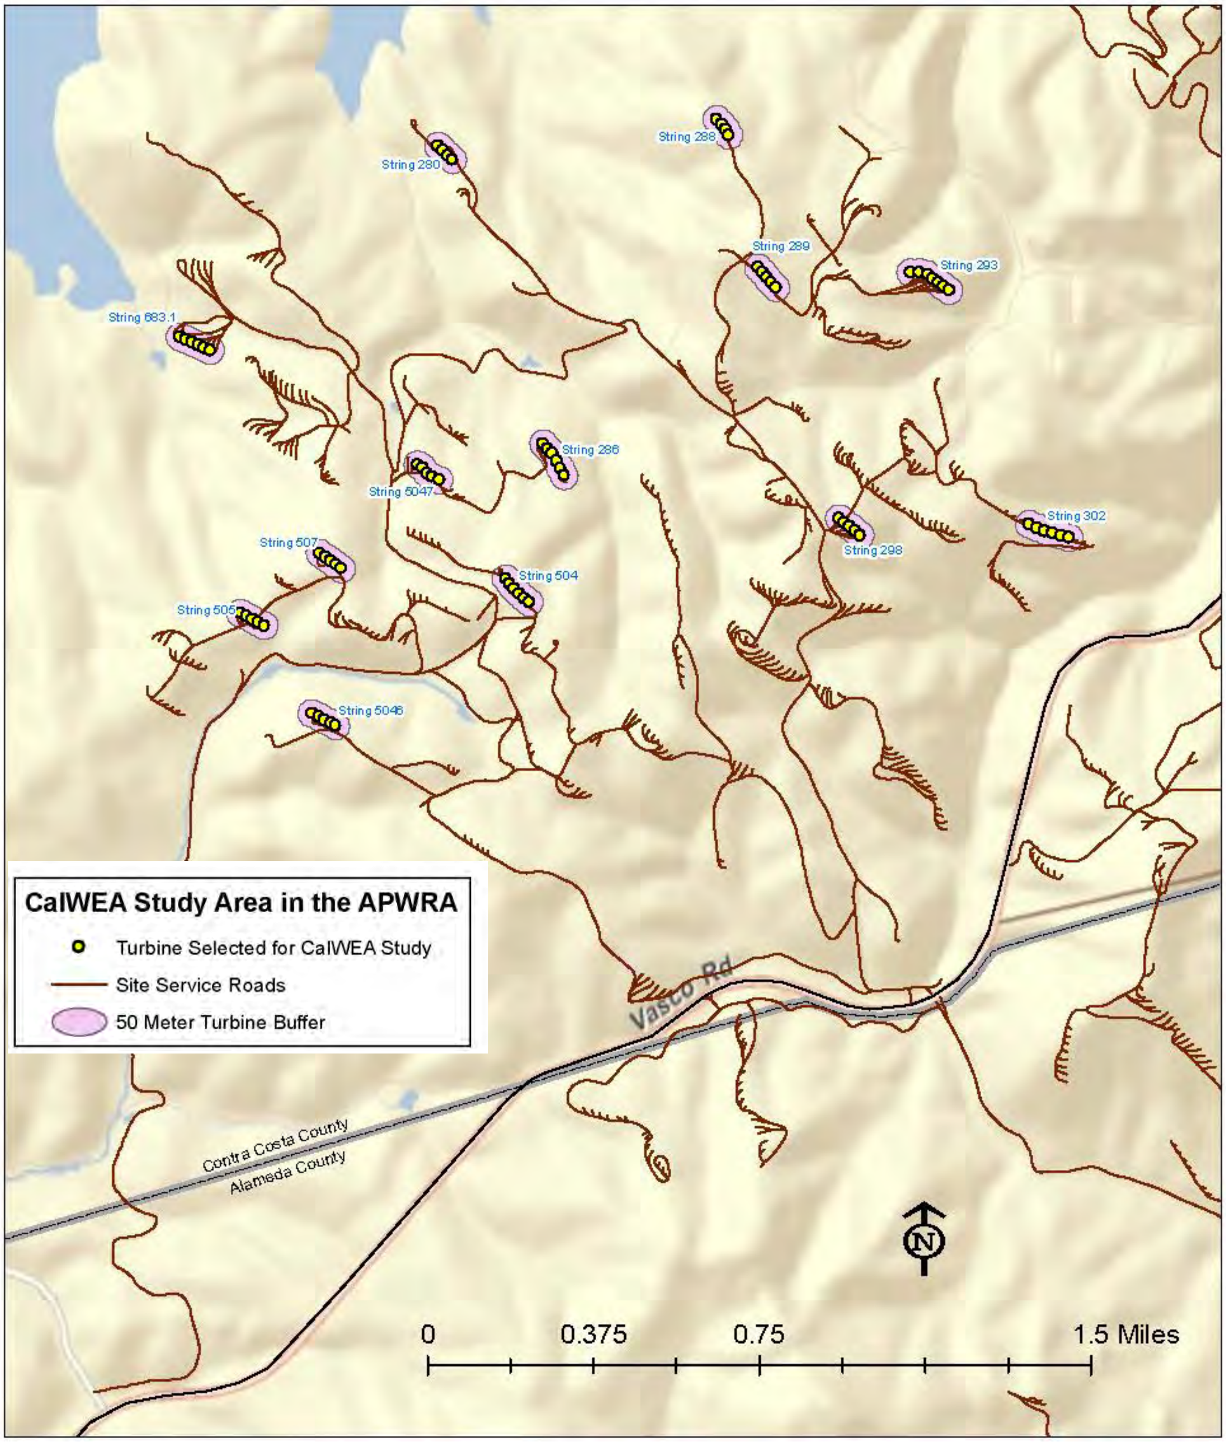
Figure 3 shows the turbine strings where the field study was conducted. A total of 13 strings (four to seven turbines per string) were searched from January to April 2011. Strings were selected primarily so that search plots would not be mutually visible to ensure that searchers did not know the location of trial carcasses. Strings were also selected to represent the range of topological conditions and vegetation types in the Altamont. Strings were grouped into four blocks in which carcasses were concurrently placed and then monitored for four to six weeks. Blocks also served as a surrogate for vegetation and meteorological conditions over time. All strings monitored during the study's field trials as detailed below were located in the APWRA north of Vasco Road.

Before conducting the field study, a pilot study was conducted. This pilot study phase was used to test the work flow to fit the project resources and schedule and to test the field methods. The first block (Block 1) of the study area was used for the pilot study. Most of the same personnel were employed for block 1 as for other blocks. Block 1 was conducted at the same study site as the other blocks but with four strings instead of three. After the pilot study, the number of strings per block was set to three, and the number of placed trial carcasses was set to six bats and eight small birds per string.

---

[1] The natural communities and land cover types identified in the Natural Community Conservation Plan (NCCP) for the APWRA include agricultural land, annual grassland, alkali grassland, seasonal wetlands, alkali wetlands, perennial wetlands and ponds, riparian woodland and streams, chaparral, oak woodland, and conifer forest.

Figure 3: Field Study Wind Turbine Strings



Source: NextEra Energy Resources

Project field managers marked and randomly placed birds and bats and oversaw the recording of the carcasses and reporting of the data collected. The project field managers visited the strings every two days in order to verify the presence or absence of individual birds and bats. All birds and bats were uniquely marked, and any displacement of a bird or bat from the original location was observed and the new location noted for future reference. At the location of each bird or bat, project field managers took measurements of vegetation height. Project field manager observations provided an independent measure of the "true" number of birds and bats available for detection. Generally, six bats and eight birds were placed along each string. Halfway through the study, one large-sized bird was placed at each string within the block along with the standard six bats and eight small birds.

Once a week, a field technician searched an area around the study strings at a typical sampling walking pace, looking for any bird or bat carcasses.[2] On a typical day, a field technician conducted two string searches, averaging two to three hours per string, covering three to six acres. The field technicians were ignorant of the presence or absence of birds and bats at any specific string location. The field technicians recorded the position of observed carcasses. Project field manager status checks were timed to include checks on days that field technicians searched study strings in order to establish the true presence of carcasses available for detection by the field technicians. (To minimize false negative detections while maintaining field technician "blindness," a cryptic system of marking carcass positions for project field managers was used.) Table 1 lists the field equipment used by the 11 field staff employed in the study.

Table 1: Equipment Used in the Field Study

Study Field Equipment

The Data Dictionary in Appendix C lists all the variables recorded, including weather information collected from January 1, 2011 through May 1, 2011 from the weather station at the Livermore, California, airport, and topographical variables recorded at each sampling location.

---

[2] Variable walking speed and direction across or along the ridge were not taken into account in this study, but would be interesting to consider in a future study.

Specific Study Sampling Procedures

Three procedures comprised the field study sampling methods:

- The placement of carcasses at study strings by project field managers.
- Blind carcass searches of study strings by field technicians.
- Status checks of placed carcasses at study strings by project field managers.

Carcass Placement

The purpose of the carcass placement procedure is to generate known random positions of marked carcasses at study strings.

Sources of Carcasses

Carcasses were provided by the following. For a variety of reasons, not all carcasses received were used during the field study.

- ***Bat*** carcasses: the Michigan Department of Community Health, Lansing, Michigan; Texas Christian University Department of Biology, Fort Worth, Texas; the Idaho State Department of Agriculture, Boise, Idaho.
- ***Brown-headed cowbird*** (*Molothrus ater*) carcasses: TW Biological Services, Fillmore, California; U.S. Department of Agriculture Animal and Plant Health Inspection Service/Wildlife Service, National Wildlife Research Center, Bismarck, North Dakota; Griffith Wildlife Biology, Calumet, Michigan.
- ***Large bird*** carcasses: Altamont Infrastructure Company, Livermore, California.

Carcass Position

The search area was defined by a 50 meter buffer created around turbines at study strings. A grid of 10-meter by 10-meter cells was projected over this search area. Topographical information was recorded for each cell (see Data Dictionary, Appendix C).

Grid cells were randomly selected for carcass placement. After grid cell selection, a project field manager would go to the approximate position of the selected grid cell and toss the marked carcass. The precise location of the carcass was recorded, including distance and bearing to the nearest turbine including the Global Positioning System (GPS) coordinates. In addition, the vegetation height immediately around the carcass position was measured. To help the project field managers find these selected carcass positions on future visits, a marker (small wooden stake) was cryptically placed 10 meters away from the carcass in such a way that a line segment was created by the position of the nearest turbine, carcass, and the marker.

Marked Carcasses

In order to maximize the project field managers' ability to identify individual trial carcasses, trial bird and bat carcasses were marked. Bird carcasses had a small amount of black tape attached to each leg marked with a unique obscured carcass identification number. In addition, the tips of the trial birds' flight feathers were cut. The tips of the trial bat carcasses' wings were taped and marked with a unique carcass identification number.

Table 2 shows the schedule for monitoring of the strings. The project field managers placed six bats and eight brown-headed cowbirds – referred to below as "small birds" – at each string, and placed one additional large bird at each string in Blocks 3 and 4. The goal was to run each block experiment for a six-week period, but logistical constraints sometimes shortened the time period, so that the actual durations ranged from 29 to 47 days. The first block experiment started on January 7, 2011, and the last block experiment ended on April 30, 2011.

Table 2: Summary of Sampling Design

Block #	String #	Turbine Address Range	Small bird carcasses placed at start of trial	Bat carcasses placed at start of trial[1]	Incidentally found carcasses added to study[2]	Trial dates (2011)	Trial Length (days)
1	280	2206-2209	8	6	2	Jan 7-Feb 12	36

Carcass Searches

The purpose of the carcass search procedure was to generate detection events of placed carcasses over time.

Field Technician Searches

Each study string was searched six times (once a week) over as many as six weeks. Each string search was conducted by one field technician who searched the entire 50-meter buffered search area using parallel transects, with an inter-transect distance of 6 to 8 meters depending on vegetation height and terrain (Figures 4, 5, and 6). Strict survey blindness was maintained by having each field technician search every study string only once over each six-week period, instructing the field technicians to not communicate found carcasses with each other, and to keep the number and position of marked carcasses a secret. Field technicians used range finders, compasses, and hand-held GPS receivers to navigate the search plots.

Figure 4: Conducting a Search

Photo Credit: EcoStat, Inc.

Figure 5: Searching in Short Grass

Photo Credit: EcoStat, Inc.

Figure 6: Searching in Tall Grass

Photo Credit: EcoStat, Inc.

In general, winter in the APWRA exhibits short vegetation starting to green due to rain. As temperature rises and precipitation continues, vegetation height increases and peaks in May.

Carcass Records

When a field technician detected a complete or partial carcass, or a collection of 10 or more feathers, a carcass record was created (Figures 7 and 8). In addition to placed marked carcasses, field technicians also found "natural" or incidental fatalities, which were also recorded. The Data Dictionary (Appendix C, Table C-1) lists all the variables contained in the final data set, including the data field technicians recorded when a carcass was found.

Figure 7: Fresh Bird Carcass

Figure 8: Partially Removed Carcass

Photo Credit: EcoStat, Inc.

Carcass Status Checks

The purpose of the carcass status check procedure is to rigorously verify the true status (presence, position, and condition) of known marked carcasses, both placed and incidentally found, at study strings.

Status Checks

Project field managers checked the status of all known carcasses every 48 hours and on days that field technician searches occurred (Figure 9). A project field manager found the last known location of a carcass utilizing a range finder, a compass, a GPS receiver, and a carcass marker. If an unknown carcass was found during a status check, the project field manager would collect and record data on its position and condition. (See Appendix C for complete list of data recorded for unknown carcasses.)

Project Field Manager Detection Types

Project field managers used range finders, compasses, and GPS receivers to find the approximate location of a placed carcass. If the carcass was not immediately detected, the carcass marker was sought out. The marker and turbine indicated a more precise carcass position. If the carcass was still not found, the position, the marker and turbine address became the point of origin for an intensive survey around this carcass to investigate if the carcass had been moved by scavengers, degraded due to abiotic weathering processes such as wind and rain, or was removed. This intensive survey was typically conducted as a flushing search, a tight spiral transect out to 20 meters from the assumed last carcass position and again back to the point of origin reversing direction to maximize the view shed around obstructions such has high vegetation and rocks.

In addition to finding a placed carcass by its GPS position, marker, or a flushing search, new carcasses or carcass positions were found incidentally when project field managers walked between carcass positions or by field technicians during their carcass searches.

Figure 9: Project Field Manager Conducting a Status Check

Photo Credit: EcoStat, Inc.

Fractured Position, New, and Unknown Carcass Identification Numbers

Carcass scavenging sometimes fractured the carcass sign into multiple positions. If these carcass parts were distinct and more than 10 meters away from the initial carcass position, an additional carcass position was established and identified by a lettered suffix added to the carcass identification number (*e.g.,* 0121B). These newly established carcass positions were then checked along with other known carcass positions.

Occasionally new fatalities were found by field technicians during carcass searches or when Project field managers conducted status checks. These new carcasses were identified with a carcass identification number including the string number, the letter U, and the number of new fatalities found at that string (*e.g.,* 302U-01). These new fatalities were checked along with all other known carcass positions.

Sometimes a marked carcass was found but its carcass identification number was unknown because the identifying tape was missing due to scavenging actions. These unknown marked carcasses were identified with a carcass identification number including the string number, the letter M, and the number of marked carcasses found at that string (302M-01). These unknown marked carcass positions were checked along with all other known carcass positions. Later a known carcass identification number was assigned to the carcass position based on its proximity to plausible known marked carcass positions.

Negative Detections

In order to maximize the certainty of a carcass position's removal, project field managers checked the negative presence (absence) multiple times before recording the removal of a carcass position. After a project field manager conducted three consecutive status checks, including flushing searches, with negative presence outcomes, the carcass position was declared removed and no longer part of future status checks. Once the carcass was confirmed removed, the time of removal was set consistent with the first observation time (this time is needed for the determination of the carcass persistence curve).

Quality Assurance/Quality Control

High frequency of data entry and field checks helped to assure the data was accurate:

- Data sheets from field technicians were collected after they completed their searches the same day and checked for completeness. The positions of any fatalities they found were also verified in the field on the same day by project field managers.
- Project field managers entered data into an Excel spreadsheet two to three times a week, because the data was needed to determine the status checks schedule.

If any questions arose when entering data, the data was rectified by asking the observer, using photos and GIS.

Results of the Field Sampling

Carcass Detections

Table 2 shows the number of trials in which a bird or bat carcass was truly on the ground, and a searcher had a chance of detecting the carcass. Carcasses that persisted over time contributed more to the number of trials than those that were removed from the study quickly.

Differences in the habitat types of the blocks may account for differences in carcass persistence, as well as the number of days on which a search occurred. Blocks are representative of changes in grass height over time; however, blocks were not selected based on specific ecological or habitat conditions. The chance of detecting a bird or bat was not equal for each search, and was found to be a function of vegetation height and carcass age. Topographical variables (*e.g.*, slope) and meteorological variables (*e.g.*, precipitation) were evaluated in addition to vegetation height, but were not found to be correlated to mortality at this site.

Table 3 summarizes the percentage of search opportunities with carcasses detected over the entire study. In practice, a single trial is implemented in which a fixed number of carcasses are observed. Each carcass has one chance of observation.

Table 2: Percent of Birds and Bats Observed for Each Block

Block	Species	Number of individual observations where the carcass was truly present[1]	Percent Detected	Average Vegetation Height (inches)
1	Bat	83	16.9	2.2
2	Bat	63	4.8	3.4
3	Bat	60	1.7	5.6
4	Bat	42	4.8	7.6
1	Small Bird	72	18.1	2.6
2	Small Bird	63	17.5	3.5
3	Small Bird	38	7.9	6.1
4	Small Bird	50	22.0	6.1
3	Large Bird	17	58.8	6.3
4	Large Bird	14	78.6	8.4

[1] Note: individual carcasses could have several chances for observation during the study

Source: EcoStat, Inc.

Table 3: Percent of Birds and Bats Observed in Study

Species	Number of individual observations where the carcass was truly present[1]	Average Vegetation Height (inches)	Percent Detected
Bat	248	4.3	8.1
Small Birds	223	4.2	17.0
Large Birds	31	7.2	67.7

[1] Note: individual carcasses could have several chances for observation during the study

Photo Credit: EcoStat, Inc.

Table 4 shows the chance that a carcass was observed on the first observation date. The number of bat carcasses observed on the first observation date is 14 percent. Note that the percentages observed on the first date are larger than found over all possible observation dates. This finding could be linked to increased difficulty with observing older carcasses.

Table 4: Percent of Birds and Bats Observed on First Observation Date

	Percent Detected
Bat	**14.1**
Small Birds	**22.1**
Large Birds	**83.3**

Carcass Persistence Probability

In this section, the scavenging rate at the level of string, block, and entire study area is examined. Relationships between carcass persistence and key covariates, such as vegetation height, are also examined. The persistence of a carcass on the field was modeled using a two-parameter Weibull distribution with the following model structure.

The density function for Weibull[3] distributed carcass persistence times is the following:

$$p(t_i|\alpha,\lambda_i) = \alpha {t_i}^{\alpha-1} \exp(\lambda_i - \exp(\lambda_i)\, {t_i}^{\alpha})$$

Where λ is the scale parameter, t_i is the time of event i, and α is the shape parameter of the Weibull probability density function.

The corresponding carcass persistence function can be written as follows:

$$S(t_i|\alpha,\lambda_i) = \exp(-\exp(\lambda_i)\lambda_i^{\alpha})$$

Where S is the probability of carcass persistence (survival or non-removal from the field), and t_i is the time (days) that the carcass was observed on the field since the start of the study.

If covariates (*i.e.*, grass height, distance to bird or bat from the searcher, topographical features, etc.) are linked to λ with $\lambda_i = x_i'\beta$, where x_i is a vector of covariates corresponding to the *i*th observation (here, an observation is a survey date) and β is a vector of random parameters, the log-likelihood function is written as:

$$l(\alpha,\beta|t,x) = \sum_{i=1}^{n} v_i(\log(\alpha) + (\alpha-1)\log(t_i) + x_i'\beta) - \exp(x_i'\beta)\, t_i^{\alpha}$$

The above model was implemented using a Bayesian paradigm with prior distributions:

$$\beta\text{: N}(0,10000)$$

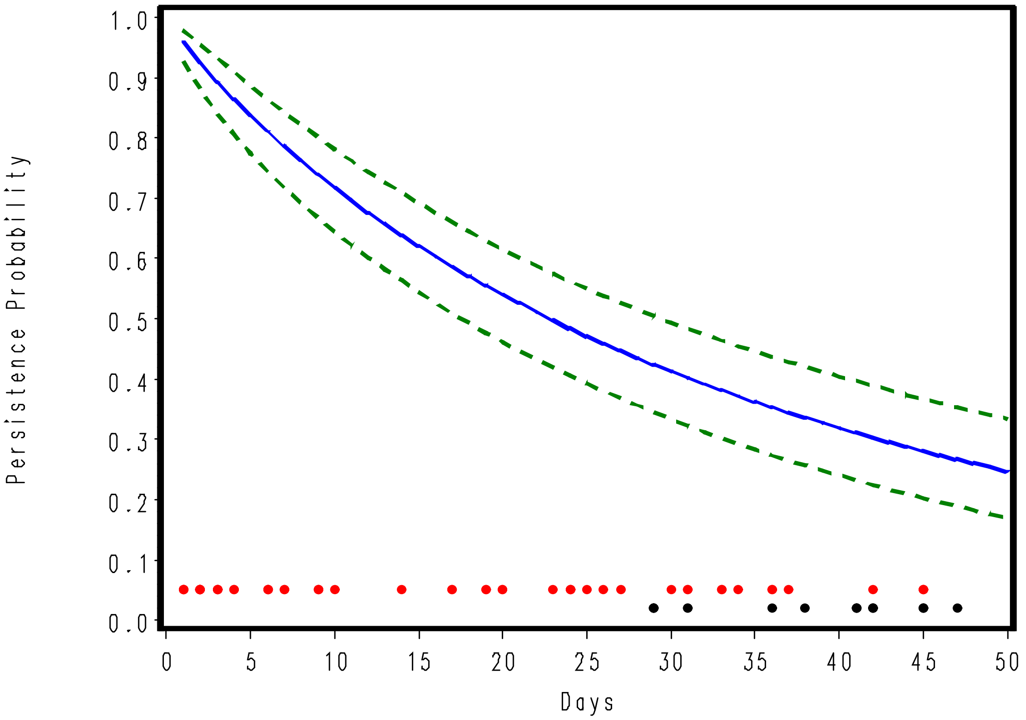
$$\alpha\text{: Gamma}(0.001, 0.001)$$

Also, in some cases, the model was implemented without λ linked to covariates. Note that v indicates whether the observation is an actual failure time (v=1) or a censoring time (v=0). An observation is considered censored if the event of interest (in this case, the carcass is removed) does not occur within the timeframe of the study. A censored observation is defined as a record where the event (removal), has yet to occur (but, may occur if the record was tracked through time for a longer period). Results of the carcass persistence modeling exercise are shown below in Figures 10-13. These graphical presentations of the carcass persistence curves display the variability in probability within the data base. The curves are not adjusted for grass height, or other possible covariates.

---

[3] The Weibull distribution is a continuous probability distribution used in survival analysis, which involves the modeling of time to event data.

Figure 10: Carcass Persistence Probability for All Bats in the Study



With 90 percent Credible Intervals, dashed line

Two-Parameter Weibull Survival Model

Red dots indicate a removal; Black dots indicate a censored[4] record
Note: A single bat can be viewed more than once during the course of the study

Source: EcoStat, Inc.

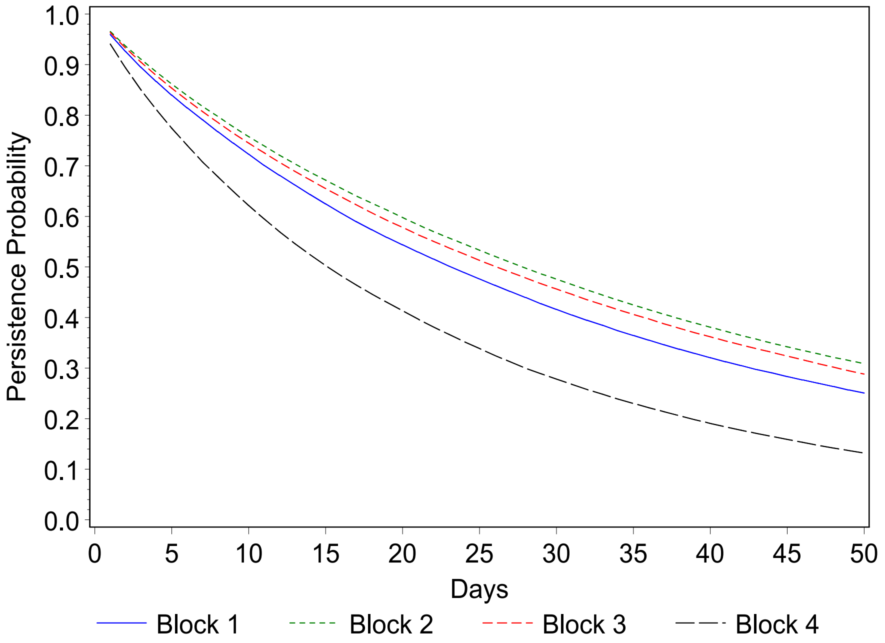
The carcass removal rate was high over the first two weeks and then the removal rate exponentially decreased. Red dots in Figure 10 indicate a constant rate of removal. Approximately 30 percent of bats were not removed (black dots).

Changes to grass height and other biological metrics over the study period may explain some of the differences in Figure 11. (However, no formal analysis of this subject is possible due to lack of rigorous field measurements). The statistical model does not result in a probability curve for large birds due to the low removal rate (one carcass).

---

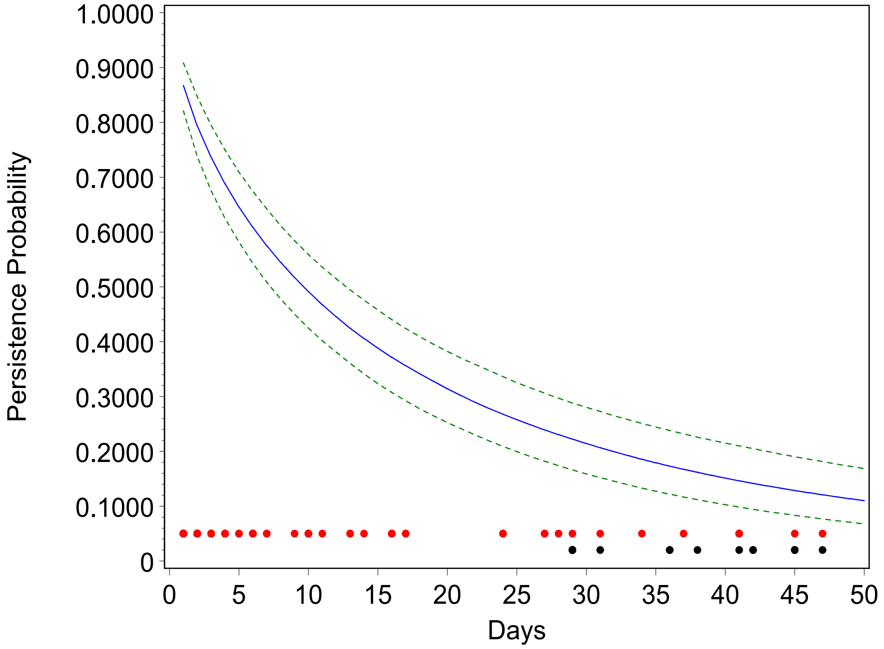
[4] "Censored" means that the carcass remained on the ground (was not removed) when the trial ended.

Figure 11: Block-Specific Persistence Probability for All Bats in the Study



Source: EcoStat, Inc.

Figure 12: Persistence Probability for Small Birds in the Study

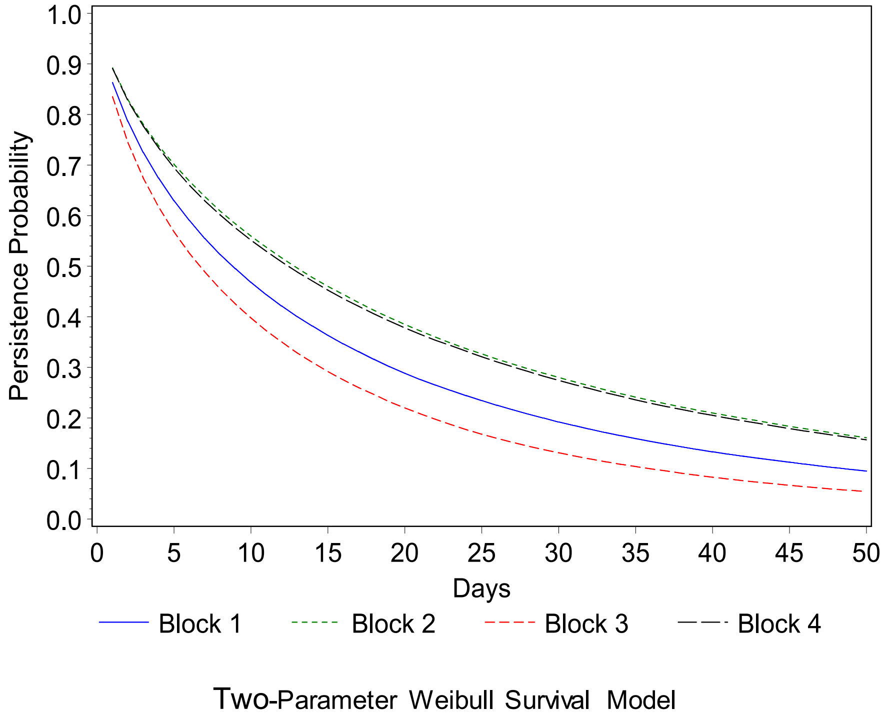


Dashed lines show 90 percent credible intervals

Red dots indicate a removal; Black dots indicate a censored record

Source: EcoStat, Inc.

Figure 13: Block Specific Persistence Probability for Small Birds in the Study



Source: EcoStat, Inc.

These curves confirm that the rates of carcass removal were greater in the first two weeks, and that most carcasses were removed within six weeks.

Searcher Proficiency

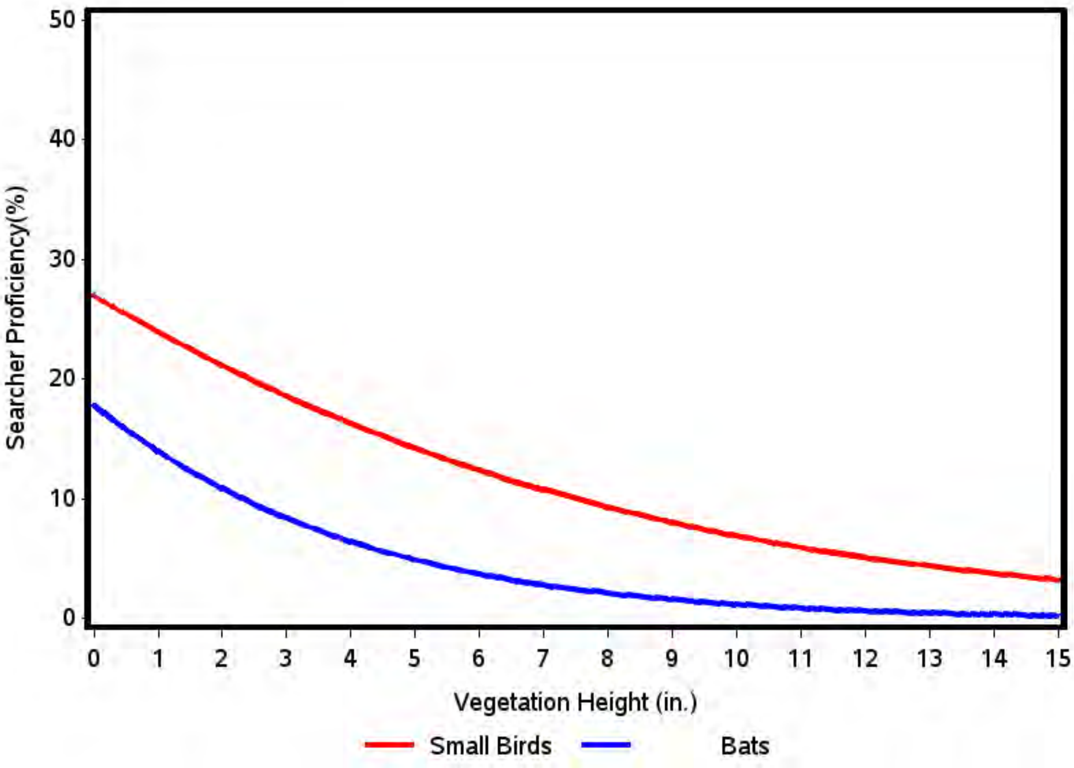
The magnitude of the searcher proficiency rate will be site specific, and will be a function of environmental and topological variables. In this study, searcher proficiency was significantly related to vegetation height (Figure 14). In addition to showing that searcher proficiency is a time-dependent process, Figures 14 and 15 clearly indicate that the shape of the searcher proficiency curves (with time and vegetation height) differ for birds and bats, and for small and large birds.

A key contribution of this study is the findings associated with bats. Statistics derived from this study indicate that, on average, searcher proficiency of bats is roughly half that of small birds. Large birds in this study were detected approximately 70 percent of the time. From a specific carcass perspective, approximately 30 percent of all small birds in the study were detected at least once, while only 19 percent of the bats were detected at least once.

The above rates for small birds are consistent with published literature values. For bats, however, the incorporation of time-based functions of searcher proficiency will have a significant impact on the resulting bat fatality estimation.

In this study, the searcher proficiency for small birds and bats was found to be similar after approximately 25 days, with the largest difference seen initially after carcass placement when the carcasses were fresh. An approximate 15 percent difference is seen between searcher proficiency in birds and bats with fresh carcasses. The searcher proficiency for birds and bats approached 2 percent after 30 days. This finding has implications for interval length in post-monitoring studies, where this study points to shorter intervals in order to maximize the chance of detecting a carcass on the ground.

Figure 14: Searcher Proficiency as Function of Vegetation Height for Brown-Headed Cowbirds and Bats, Integrated Across All Other Possible Covariates

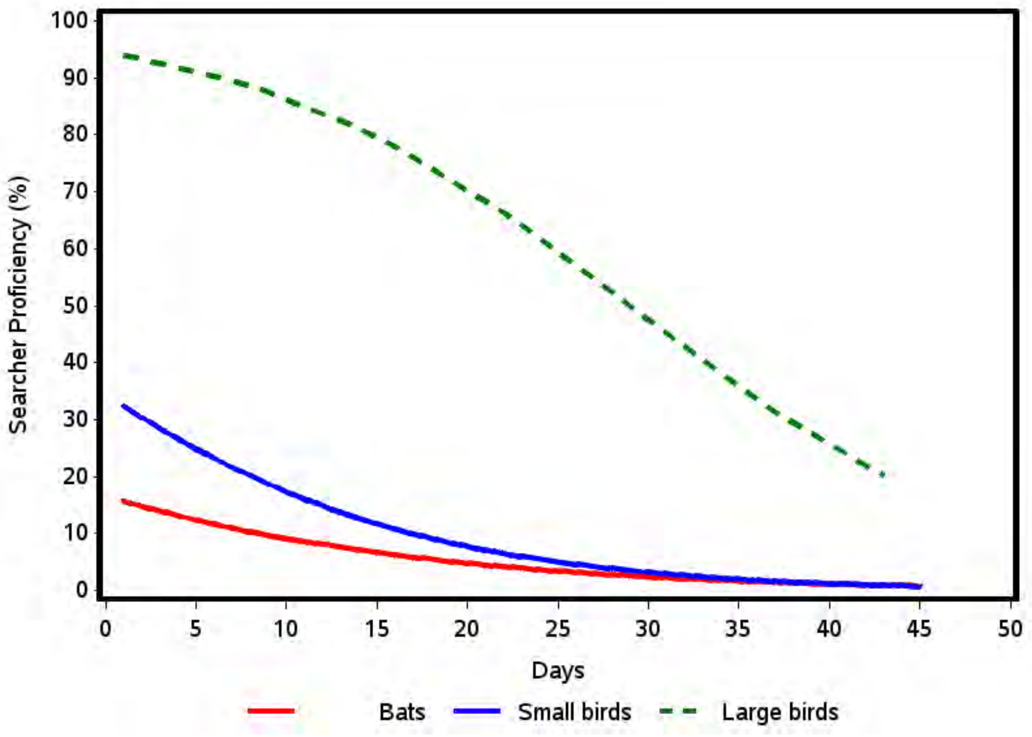


Source: EcoStat, Inc.

Bats are harder to find than birds, and all carcasses have low probability (less than 10 percent) of detection by field technicians after three weeks. The study's finding that carcasses have the highest chance of being detected during the first two weeks has implications for study design. (Note that Figure 15 includes carcasses that have been scavenged but not removed.)

Table 7 presents the distance between the observed bird or bat, and the field technician. Statistics are calculated for the entire study, using all possible observations. Smaller carcasses are clearly shown to be found closer to the observer, on average. The distance sighted suggests that transects should be closer together; this study shows that 6 to 8 meters (a standard distance used by many investigators) is too far apart for many small bird and bat detections.

Figure 15: Searcher Proficiency of Small Birds and Bats Over Time, Integrated Over All Other Covariates



Source: EcoStat, Inc.

Table 7: Distance Between Observed Carcass and Field Technician

Species	Minimum Distance (meters)	Mean Distance (meters)	Maximum Distance (meters)
Bat	1.0	1.7	8.0
Small Birds	1.0	2.2	10.0
Large Birds	1.0	9.0	41.0

Source: EcoStat, Inc.

One problem with most estimators is that they must address a mix of species and ages of carcasses, which is complex. The time and age of carcasses matter for detection; the data reveal an often overlooked time dependency to searcher bias, combined with persistence.

Questions that could be explored with further research include whether increasing the searcher time per string (decreasing walking speed) results in higher detection rates, and whether it would be better to search one area thoroughly or search more areas.

CHAPTER 3: Fatality Estimation Equation Analysis

The objective of this section of the compare commonly used equations. Based on the assumptions underlying each equation, and the mathematics inherent in the equations, computer simulation is used to compare and contrast the expected true fatality rates among the equations evaluated. The equations are explored and evaluated using the concept of statistical bias and variance.

Description of Analysis

Estimating the true (or actual) fatalities of a specific species of bird or bat, related to a particular wind power generating facility during a specified time period, is a challenging task. Typical data supporting such estimates consist of collections $\{C_{ij}\}$ of counts of carcasses discovered by search teams in delineated search areas near a number of turbines (here indexed by i) at the end of successive search periods (here indexed by j), of varying length $\{I_{ij}\}$ (in days).

The simplest approach to estimating the total number M_{ij} of fatalities due to turbine i in time period j would be the raw count, $\widehat{M}_{ij} = C_{ij}$. This would be exactly correct under the simplistic assumptions:

- S_1 Each period begins with no carcasses in the search area;
- S_2 Each fatality caused by turbine j during period i leads to a (unique, single) carcass in the study area;
- S_3 There are no other sources of carcasses in the study area;
- S_4 Each carcass remains throughout the period;
- S_5 The search team discovers and removes every carcass.

Under these assumptions the total number M_{ij} of fatalities could be estimated perfectly by

$$\widehat{M}_{ij} := C_{ij}.^{5}$$

Each of the assumptions above is false to at least some degree, leading C_{ij} to be a badly distorted estimate of M_{ij}. Some of the reasons include:

- Experiments (for example, see http://www.altamontsrc.org/alt_rl.php) have shown that search teams usually discover only a fraction of existing carcasses (estimates ranging from 13 percent to 88 percent have been reported in the literature), violating S_5. The undiscovered carcasses will be present in the search area at the beginning of the subsequent period, violating S_1.
- Fatalities from turbine j may lead to carcasses outside the search area, violating S_2.

---

[5] Note the equals sign (=) indicates "defined as."

- Carcasses from fatalities caused by another turbine or from an unrelated source may fall into the search area, or carcasses from fatalities preceding the test period may persist into the period, violating S_3.
- Scavengers may remove carcasses before they are discovered by the search team, or carcasses may degrade so much that they elude discovery, violating S_4.

A number of authors have published more sophisticated estimation formulas for the number M_{ij} of birds or bats killed, intended to correct the biases induced by these issues. The following discussion is intended to explain the implicit assumptions that underlie four of these formulas, illustrating how they differ, and to offer suggestions for choosing among them or alternatives for the purpose of making reliable estimates of fatality.

The Estimating Equations

The authors study fatality by constructing a mathematical model in which the number C_{ij} of turbine-related carcasses discovered in the i^{th} spatial region at the end of the j^{th} temporal period is treated as a random variable. Each of the estimation formulas considered here begins as an equation expressing the *expected number* of carcasses counted, $\mathrm{E}[C_{ij}]$, as a function of the actual number M_{ij} of fatalities and of some other factors (or estimates of them), under some assumptions about how scavenging and fatality proceed. This section considers what implicit assumptions lie behind these equations, offering some perspective on them and also some generalizations.

The authors differ in their choice of which letters to use as variable names for which quantities. To simplify comparing their estimation formulas, this report assigns common notation for all of them. Upper-case letters denote quantities which are (or could be, in principle) observed; lower-case letters denote model parameters. Table 8 presents the notation used here. "Hatted" quantities such as "$\widehat{M}_{ij}$" denote estimates of the corresponding quantities.

Even though observations are taken only at a few discrete times, it is useful to think of fatality and removal as processes that occur progressively over the time interval. Time is treated as a continuously-varying quantity t, measured in days, ranging from zero to I_{ij} during each study interval. The instantaneous rates of fatality and removal, and the levels of searcher proficiency, may vary in time and may depend on a variety of covariates. In a more detailed modeling effort the proficiency s_{ij} (the probability of discovery of a particular carcass) would depend on the searcher's skill, the time lapse from fatality to search, and various covariates including the vegetation height and lighting conditions. Carcass removal rates r_{ij} would also change as carcasses age, and might depend on other covariates, leading to time and covariate dependence for persistence probabilities p_{ij} and average durations t_{ij}.

Table 8: Common Notation for Observable Quantities (Upper Case) and Parameter Values (Lower Case) for All Estimation Formulas

At turbine i in time interval j		
C_{ij}	(count)	= number of carcasses counted
I_{ij}	(search interval)	= search interval length (in days)
M_{ij}	(mortality)	= true number of carcasses during interval
p_{ij}	(persistence probability)	= probability a carcass remains unremoved until next search
r_{ij}	(removal rate)	= probability per day of carcass removal by scavengers and other processes
s_{ij}	(search proficiency)	= probability a carcass will be discovered
t_{ij}	(persistence time)	= average number of days a carcass remains unremoved

Source: Dr. Robert Wolpert

In this discussion, each of these parameters is treated as constant during each search interval, set to their $average$ values in region i and epoch j. Models reflecting their dependence on time and covariates are under development and will be described elsewhere.

Common Assumptions

All four of the estimation equations below embody some common simplifying assumptions, most of them approximately correct or easily addressed:

A_1: Each fatality caused by turbine j during period i leads to a carcass in the study area.

- In each of the approaches below this can be relaxed by including an additional factor $1/\hat{\pi}_{ij}$, where $\hat{\pi}_{ij}$ is an estimate of the fraction π_{ij} of carcasses from the j^{th} turbine that fall into the study area during the i^{th} time period. Most authors adjust for this.

A_2: There are no other sources of carcasses in the study area.

- Searchers are trained to distinguish turbine fatalities from others, and search areas are sufficiently widely separated to ensure that few if any inappropriate carcasses will be counted.

A_3: Carcass arrival times are uniformly distributed over the interval $[0, I_{ij}]$.

- Actual fatality rates will vary over time due to diurnal patterns, weather dependence, migratory patterns, and for other reasons, but the effects should average out over time with no significant effect on estimates.

A_4: Quantities that vary over the time interval or that depend on covariates are adequately represented by their average values.

- This leads to considerable simplification, and holds approximately if the variation is small. See Discussion below for notes on how it may affect estimates if variation is not small, and on how it could be addressed.

Implicit assumptions specific to each particular estimation approach are described below.

Erickson & Johnson's Equation

An early attempt to reduce bias, attributed by Shoenfeld (2004, Equation (2)) to Erickson, Strickland, Johnson and Kern (1998) and by Huso (2011, §3.2) to Johnson, Erickson, Strickland, Shepherd, Shepherd and Sarappo (2003) is

$$\widehat{M}_{ij}^{\mathrm{EJ}} = \frac{C_{ij} I_{ij}}{\hat{s}_{ij} \hat{t}_{ij}}. \tag{1}$$

If, on average, carcasses persist unremoved for only a fraction $t_{ij} < I_{ij}$ of the search interval, and if the search team's proficiency is $s_{ij} < 1$, it is reasonable to expect them to only discover a portion

$$C_{ij} \approx (t_{ij}/I_{ij})(s_{ij})M_{ij}$$

of the carcasses, leading to the estimator (1) when the uncertain quantities s_{ij} and t_{ij} are replaced with estimates and the equation is solved to construct an estimate of M_{ij}.

Exploring this in more detail, in the absence of intervention (*i.e.*, removal of carcasses by searchers) and under unchanging conditions, the long-term average number of carcasses present on the ground in the study area would reach a steady state with no systematic increase or decrease; denote the average number of carcasses at steady state by g_{ij}^{∞}. Since each of those carcasses is present for an average of t_{ij} days, the average daily fatality rate necessary to maintain that equilibrium is $m_{ij} = g_{ij}^{\infty}/t_{ij}$, so

$$g_{ij}^{\infty} = m_{ij} t_{ij}.$$

On average the total fatality in a period of I_{ij} days is $M_{ij} \approx m_{ij} I_{ij}$, so

$$g_{ij}^{\infty} \approx (M_{ij}/I_{ij}) t_{ij}$$

and on average a search team that succeeds in discovering carcasses with probability $s_{ij} < 1$ (the team's proficiency) would discover a fraction s_{ij} of these,

$$\mathrm{E}[C_{ij}] \equiv s_{ij} g_{ij}^{\infty} = M_{ij} s_{ij} t_{ij}/I_{ij}. \tag{2}$$

Replacing s_{ij} and t_{ij} by their estimates $\hat{s}_{ij}$ and $\hat{t}_{ij}$ and solving for M_{ij} leads to estimator (1), $\widehat{M}_{ij}^{\mathrm{EJ}} = (C_{ij}I_{ij})/(\hat{s}_{ij}\hat{t}_{ij})$. Because of its steady-state assumption, the validity of Erickson and Johnson's estimator $\widehat{M}_{ij}^{\mathrm{EJ}}$ (1) requires the additional assumption:

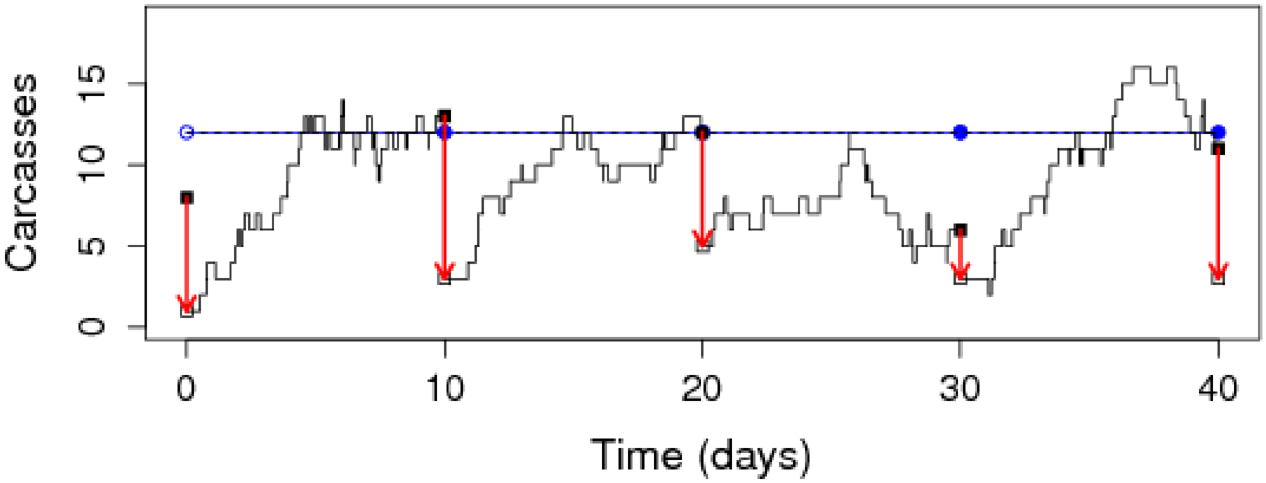
$\mathrm{A}_1^{\mathrm{EJ}}$:The system is in equilibrium at each search.

This will hold approximately whenever $I_{ij} \gg t_{ij}$, since the removal process then brings the system to equilibrium quickly, but in general it will be violated by any intervention such as the removal of discovered carcasses by search teams. If $\mathrm{A}_1^{\mathrm{EJ}}$: fails (as in Figure 16) because of interventions that remove carcasses, then $C_{ij} < s_{ij}g_{ij}^{\infty}$ on average, leading to systematic underestimation with $\widehat{M}_{ij}^{\mathrm{EJ}} < M_{ij}$ (see Discussion below).

Figure 16 illustrates four $I_{ij} = 10$-day periods. Simulated counts $G_{ij}(t)$of carcasses currently in the study area are shown as a stair-step curve, for Poisson fatality at constant average daily rate $m_{ij} = 3\mathrm{d}^{-1}$ and exponential persistence times averaging $t_{ij} = 4\mathrm{d}$. The equilibrium average value $g_{ij}^{\infty} = m_{ij}t_{ij} = 12$ is shown as a horizontal line.

The curve $G_{ij}(t)$ increases by one with each new fatality (at random times chosen uniformly from each interval $[0, I_{ij}]$), decreases by one with each removal by scavengers (after independent exponentially-distributed persistence times), and decreases at the time of each search by the number of carcasses discovered and removed. Search team proficiency for the simulation is $s_{ij} = 0.70$. Search team carcass counts appear as downward arrows, and undiscovered carcasses remain for the subsequent search period.

Figure 16: Steady-State Value $g_{ij}^{\infty} = 12$ for Erickson & Johnson's Estimator $\widehat{M}_{ij}^{\mathrm{EJ}}$ (1)



Horizontal line, beginning and ending each period at open and filled circles, respectively. One draw from random distribution (stair-step, beginning and ending each period at open and closed squares, respectively) is also shown, with discovered carcasses removed (in violation of $\mathrm{A}_1^{\mathrm{EJ}}$).

Source: Dr. Robert Wolpert

A Variation: Shoenfeld's Periodic Equation

Huso (2011, §3.2) attributes to Dr. Peter S. Shoenfeld (2004) the "modified" estimation formula

$$\widehat{M}^{s}_{ij} = \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}}\left[\frac{e^{I_{ij}/\hat{t}_{ij}} - 1 + \hat{s}_{ij}}{e^{I_{ij}/\hat{t}_{ij}} - 1}\right] \qquad (3)$$

Shoenfeld describes this estimator as a "periodic" variation on (1), specifically intended to address that estimator's systematic underestimation, which he suggests is about 15–20 percent in practice. The next section reviews the assumptions implicit in Equation (3).

Each period begins with carcasses that were *not* discovered and removed by the previous search team still on the ground. As the number t of days into the period increases, the number of carcasses $G_{ij}(t)$ is increased by new fatalities and decreased by the removal process, with expected value $g_{ij}(t) = \mathrm{E}\left[G_{ij}(t)\right]$ tending toward the equilibrium limit g^{∞}_{ij}. Under the assumptions listed below, the mean satisfies a linear Ordinary Differential Equation:

$$\frac{d}{dt} g_{ij}(t) = m_{ij} - r_{ij} g_{ij}(t) = m_{ij} - g_{ij}(t)/t_{ij} \qquad (4a)$$

where $m_{ij} = M_{ij}/I_{ij}$ is the daily fatality rate and $t_{ij} = 1/r_{ij}$ is the average persistence time. The well-known solution with initial value g^{0}_{ij} is

$$g_{ij}(t) = g^{0}_{ij} e^{-t/t_{ij}} + m_{ij} t_{ij}\left(1 - e^{-t/t_{ij}}\right), \qquad (4b)$$

which begins at $g_{ij}(0) = g^{0}_{ij}$ and converges exponentially at rate $1/t_{ij}$ to the equilibrium value of $g^{\infty}_{ij} = m_{ij} t_{ij}$. The value at the time of the search ending the j^{th} time period is $g_{ij}\left(I_{ij}\right)$.

Shoenfeld's idea is to use this relation *periodically* for search scenarios where the search intervals, search proficiencies, and removal rates are approximately constant for consecutive time periods. In that case each period will end on average with the same number $\mathfrak{g}_i = g_{ij}\left(I_{ij}\right)$ of carcasses as the preceding period. By periodicity, each must begin on average with $g^{0}_{ij} = \left(1 - s_{ij}\right)\mathfrak{g}_i$ carcasses, those undiscovered by the previous search team, leading to the equation

$$\mathfrak{g}_i = \left(1 - s_{ij}\right)\mathfrak{g}_i e^{-I_{ij}/t_{ij}} + m_{ij} t_{ij}\left(1 - e^{-I_{ij}/t_{ij}}\right). \qquad (5)$$

Collecting terms, this is easily solved for:

$$\mathfrak{g}_i = \frac{m_{ij} t_{ij}\left(1 - e^{-I_{ij}/t_{ij}}\right)}{1 - \left(1 - s_{ij}\right)e^{-I_{ij}/t_{ij}}} = \frac{M_{ij} t_{ij}}{I_{ij}} \frac{e^{I_{ij}/t_{ij}} - 1}{e^{I_{ij}/t_{ij}} - 1 + s_{ij}}$$

(using $m_{ij} = M_{ij}/I_{ij}$ for the average daily fatality). The expected carcass count will be less by a factor of the proficiency s_{ij},

$$\mathrm{E}\left[C_{ij}\right] = M_{ij} \frac{s_{ij} t_{ij}}{I_{ij}}\left[\frac{e^{I_{ij}/t_{ij}} - 1}{e^{I_{ij}/t_{ij}} - 1 + s_{ij}}\right].$$

Solving for M_{ij} and replacing s_{ij} and t_{ij} with their estimates leads to Shoenfeld's (2004, Equation (1)) estimation equation,

$$\widehat{M}^{s}_{ij} = \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}}\left[\frac{e^{I_{ij}/\hat{t}_{ij}} - 1 + \hat{s}_{ij}}{e^{I_{ij}/\hat{t}_{ij}} - 1}\right].$$

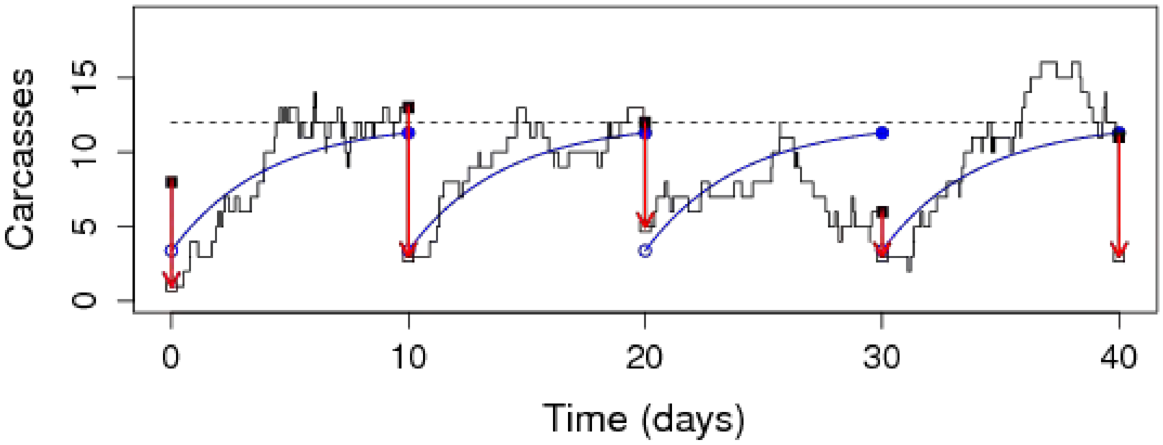
Shoenfeld's periodic approach was based on three new assumptions (as inferred from the characteristics of the equation):

A^{S}_{1}: Carcass persistence times have exponential distributions.

A^{S}_{2}: All carcasses (both old and new) have the same probabilities of discovery s_{ij}.

A^{S}_{3}: The lengths I_{ij}, rates of mortality m_{ij} and removal r_{ij}, and the proficiencies s_{ij} are approximately constant over consecutive time intervals.

Figure 17: Mean Function $g_{ij}(t)$ for Shoenfeld's "Periodic" Estimator $\widehat{M}^{s}_{ij}$ (3)



Smooth solid curve, beginning and ending each period at open and filled circles, respectively

Steady-state limit (dashed curve at $g^{\infty}_{ij} = 12$), and one draw from random distribution (stair-step, beginning and ending each period at open and closed squares, respectively) are also shown. True mortality rate is $m_{ij} = 3\mathrm{d}^{-1}$, persistence is $t_{ij} = 4\mathrm{d}$, and searcher proficiency is $s_{ij} = 0.70$.

Source: Dr. Robert Wolpert

Assumption A^{S}_{1} was needed to justify the Ordinary Differential Equation (4). Assumption A^{S}_{2} ensures that undiscovered carcasses from an earlier period are just as likely to be removed by scavengers and weathering or discovered by future search teams as are fresh carcasses (see Discussion below), justifying their inclusion for the current period. Assumption A^{S}_{3} justifies the recursion of Equation (5).

If the sampling intervals I_{ij} are long compared to the average removal times t_{ij}, then the last factor in square brackets above is close to one and (3) reduces to (1), so $\widehat{M}^{s}_{ij} \approx \widehat{M}^{\mathrm{EJ}}_{ij}$. If searches are more frequent, so search intervals I_{ij} are not long compared to residence times t_{ij}, then the estimate $\widehat{M}^{\mathrm{S}}_{ij}$ of (3) always exceeds $\widehat{M}^{\mathrm{EJ}}_{ij}$ of (1), to compensate for the smaller number of carcasses on the ground following the previous search.

Figure 17 illustrates the model implicit in Shoenfeld's estimation equation for four I_{ij} = 10-day periods. The mean value $g_{ij}(t)$for the count $G_{ij}(t)$ of carcasses in the region is shown as a solid curve, beginning and ending each search period with an open or filled circle respectively, approaching but not quite attaining the steady-state $g^{\infty}_{ij} = 12$ shown as a dashed line. One random draw of the numbers $G_{ij}(t)$ of carcasses currently in the study area is shown as a stair-step curve for constant daily mortality rate $m_{ij} = 3\mathrm{d}^{-1}$ and persistence times $t_{ij} = 4\mathrm{d}$. Search team carcass counts appear as downward arrows; undiscovered carcasses remain for subsequent search period. As before, search team proficiency is $s_{ij} = 0.70$.

Pollock's Equation

It is worth questioning *why* in practice search teams find only a modest fraction s_{ij} of carcasses. Under Shoenfeld's assumption $\mathrm{A}^{\mathrm{S}}_2$ the undiscovered carcasses are no harder or easier to find than those that were discovered— discovery failures are entirely random. But another possibility to consider is that some carcasses are more difficult to find than others, perhaps because they fell in deeper grass, or in an area with poorer light or less contrast, and that search teams find all of the most accessible carcasses. If so, then carcasses remaining on the ground after a search should *not* be included among those that might be found during subsequent periods. The next equations considered are based on an assumption that each period begins with no discoverable carcasses present.

The estimator recommended in Guidelines, suggested by Dr. Kenneth H. Pollock of North Carolina State University (2007), is

$$\widehat{M}^{\mathrm{P}}_{ij} = \frac{C_{ij}}{\hat{p}_{ij}\hat{s}_{ij}}. \qquad (6)$$

This is the estimator one would derive from a model in which the expected carcass count for the j^{th} period could be expressed as the product $\mathrm{E}[C_{ij}] = M_{ij}p_{ij}s_{ij}$ of the mortality count M_{ij}, reduced by the "persistence probability" p_{ij} and the searcher proficiency s_{ij}.

The difficulty in interpreting this equation and assessing its validity lies with interpreting the persistence probability parameter "p_{ij}", described by this study as the "probability that a carcass persists and is observable until the next search" and by the Guidelines as the "probability that a carcass has not been removed in an interval." Because some carcasses appear much earlier in the interval than others, some will be subject to removal by scavengers and weathering for longer times than others and so some will face a higher probability of removal.

Exponential Persistence Times

If persistence times have *exponential* distributions, then the probability of persisting unremoved from any time $0 \le t \le I_{ij}$ to the end of the interval is $\mathsf{P}[\tau_k > (I_{ij} - t)] = e^{-r_{ij}(I_{ij}-t)}$. Under

Common Assumption A3 of uniformly-distributed arrival times, the average probability p_{ij} that a carcass persists until the next search at time I_{ij} and the average persistence time t_{ij} is given by

$$p_{ij} = \frac{1}{I_{ij}} \int_0^{I_{ij}} e^{-r_{ij}(I_{ij}-t)}\, dt = \frac{1}{r_{ij}I_{ij}} \left[1 - e^{-r_{ij}I_{ij}}\right] \qquad (7a)$$

$$t_{ij} = \int_0^{\infty} e^{-r_{ij}\tau}\, d\tau \quad = 1/r_{ij.} \qquad (7b)$$

Combining these with (6), Pollock's estimator for exponential persistence is

$$\widehat{M}_{ij}^{\mathrm{P:E}} = \frac{C_{ij}}{\hat{p}_{ij}\hat{s}_{ij}} = \frac{C_{ij}I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}} \left[1 - e^{-I_{ij}/\hat{t}_{ij}}\right]^{-1} \quad \text{(with exponential persistence).} \qquad (7c)$$

Weibull Persistence Times

For exponentially-distributed persistence times, the probability of a carcass's removal during a day (assuming it is still present at the start of that day) does not vary with the age of the carcass. This feature of the distribution, sometimes called "memorylessness" and sometimes called "constant hazard", may not be realistic if older carcasses appear less attractive to scavengers. An alternative probability distribution commonly used to model failure times with decreasing hazard is the *Weibull* family.

Pollock's estimator $\widehat{M}_{ij}^{\mathrm{P}}$ of Equation (6) can be used with a Weibull probability distribution for persistence times exhibiting decreasing hazard, by introducing a new parameter $\alpha > 0$ (the Weibull "shape" parameter). The case $\alpha = 1$ reduces to the exponential distribution as before, but for $0 < \alpha < 1$ the hazard (*i.e.*, removal rate) falls off like the power $r_{ij} \propto \tau^{\alpha-1}$ with increasing persistence time τ. The persistence distribution is then given by

$$\mathrm{P}[\tau > t] = e^{-(r_{ij}t)^{\alpha}}, \ \mathrm{t} > 0$$

with average persistence probability and average persistence time given by

$$p_{ij} = \frac{1}{I_{ij}} \int_0^{I_{ij}} e^{-[r_{ij}(I_{ij}-t)]^{\alpha}}\, dt \ = \frac{1}{r_{ij}I_{ij}} P\left(\frac{1}{\alpha}, \left[\Gamma\left(1 + \frac{1}{\alpha}\right) r_{ij}I_{ij}\right]^{\alpha}\right), \qquad (8a)$$

$$t_{ij} = \int_0^{\infty} e^{-[r_{ij}\tau]^{\alpha}} d\tau \ = \Gamma\left(1 + \frac{1}{\alpha}\right)/r_{ij} \qquad (8b)$$

where $\Gamma(a)$ and $P(a,x)$ denote the Gamma and incomplete Gamma functions, respectively (Abramowitz and Stegun, 1964, §6.5). The resulting estimator from (6) is

$$\widehat{M}_{ij}^{\mathrm{P:W}} = \frac{C_{ij}}{\hat{p}_{ij}\hat{s}_{ij}} = \frac{C_{ij}I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}} P\left(\frac{1}{\alpha}, \left[\Gamma\left(1 + \frac{1}{\alpha}\right) I_{ij}/\hat{t}_{ij}\right]^{\alpha}\right)^{-1} \text{(with Weibull persistence),} \qquad (8c)$$

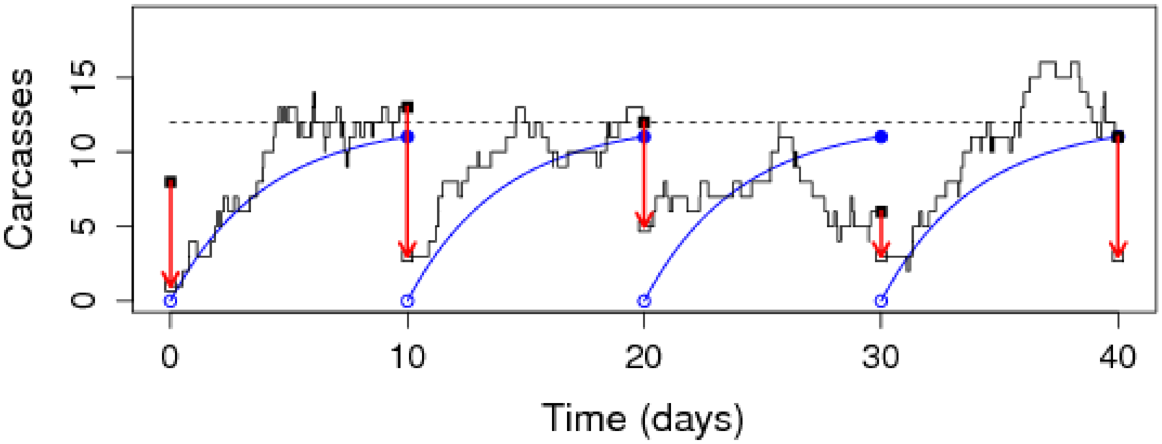
not much less tractable than the exponential version (7c).

Other interpretations of p_{ij} (for example, the probability a carcass present at the beginning of the interval will persist to the end) or other persistence distributions lead to different expressions and may require different assumptions for validity. For any persistence distribution, Pollock's estimator requires the assumption:

A_1^P: Each period begins with no discoverable carcasses.
If A_1^P: fails then $\widehat{M}_{ij}^P$ will consistently overestimate M_{ij}.

Figures 18 and 19 illustrate the model implicit for $\widehat{M}_{ij}^P$ with exponential persistence for four I_{ij} = 10-day periods. The mean value $g_{ij}(t)$ for the count $G_{ij}(t)$ of carcasses in the region is shown in each as a solid curve, beginning each search period with an open circle at $g_{ij}(t) = 0$ and ending each at a filled circle somewhat below the steady-state level of $g_{ij}^{\infty} = 12$, indicated by a dashed line. One random draw of the numbers $G_{ij}(t)$ of carcasses currently in the study area is shown as a stair-step curve for constant mortality rate $m_{ij} = 3\text{d}^{-1}$ and mean persistence times $t_{ij} = 4\text{d}$. Search team carcass counts appear as downward arrows, for proficiency is $s_{ij} = 0.70$. Following searches undiscovered carcasses remain discoverable for future searches in Figure 18, in violation of A_1^P, to illustrate possible bias, but search intervals are sufficiently long ($I_{ij} = 2.5t_{ij}$) that estimator $\widehat{M}_{ij}^P$ has a bias of only 2.5 percent.

Figure 18: Mean Function $g_{ij}(t)$ for Pollock's Estimator $\widehat{M}_{ij}^P$ (7c) with Exponential Carcass Persistence Distributions



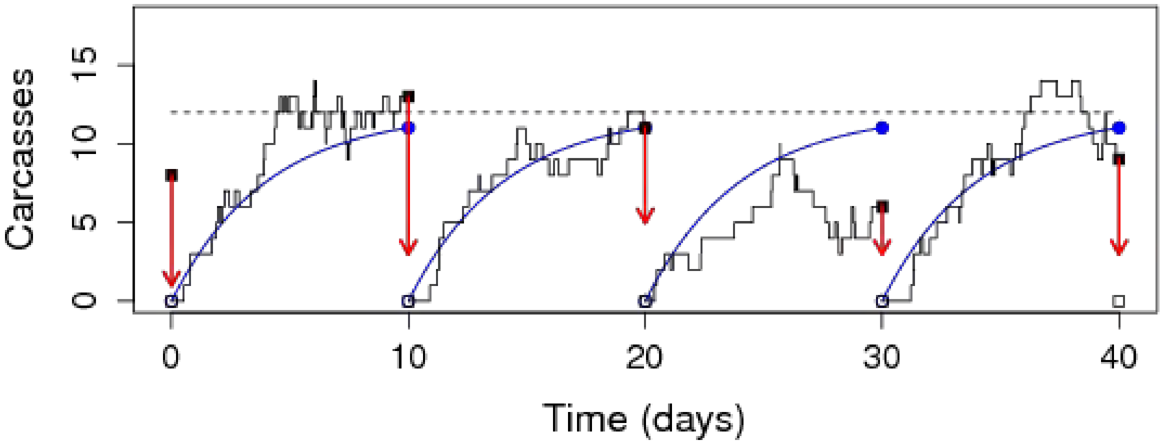
Smooth solid curve, beginning each search period with an open circle at $g_{ij}(t) = 0$ and ending each period at a filled circle

Steady state limit (dashed curve at $g_{ij}^{\infty} = 12$), and one draw from random distribution (stair-step, beginning and ending each period at open and closed squares, respectively) are also shown. True mortality rate is $m_{ij} \equiv 3\text{d}^{-1}$, persistence is $t_{ij} = 4\text{d}$, and search team proficiency is $s_{ij} = 0.70$. Undiscovered carcasses are allowed to remain following searches, in violation of A_1^P.

Source: Dr. Robert Wolpert

For contrast, all carcasses are removed following searches in Figure 19, consistent with A_1^P.

Figure 19: Simulation Illustrating $\widehat{M}_{ij}^{\mathrm{P}}$ (7c) with Exponential Persistence Distributions with Carcasses Removed Following Searches, so $\mathrm{A}_1^{\mathrm{P}}$ Holds



Source: Dr. Robert Wolpert

Huso's Equation

Huso (2011) expresses the concern that in some study designs the interval I_{ij} between successive searches may far exceed the expected persistence time t_{ij} of carcasses. In that case she proposes to reduce the value used for I_{ij} to an "effective" time interval length $\tilde{I}_{ij} < I_{ij}$, sufficiently long that the random persistence times $\{\tau_k\}$ (with mean t_{ij}) will only exceed this effective time with small probability $\mathsf{P}[\tau_k > \tilde{I}_{ij}] \le 1\,percent$, and regard the carcass count as appropriate for just the last $\tilde{I}_{ij}$ days of the interval. The resulting estimate is then scaled by the factor $(I_{ij}/\tilde{I}_{ij})$ to achieve an estimate $\widehat{M}_{ij}^{\mathrm{H}}$ for the full interval of I_{ij} days. Under her assumption of exponential distributions for persistence times $\{\tau_k\}$, $\hat{I}_{ij} \equiv \hat{t}_{ij}\log(100)$ (about 4.6 times the estimated mean persistence time $\hat{t}_{ij}$), leading to Huso's estimator

$$\widehat{M}_{ij}^{\mathrm{H}} = \begin{cases} \dfrac{c_{ij}I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}\left(1-e^{-I_{ij}/\hat{t}_{ij}}\right)} & I_{ij} < \hat{I}_{ij} \\ \dfrac{c_{ij}I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}(0.99)} & I_{ij} > \hat{I}_{ij} \end{cases} = \frac{c_{ij}I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}\left[0.99 \wedge \left(1-e^{-I_{ij}/\hat{t}_{ij}}\right)\right]}. \tag{9}$$

This is expressed quite differently, but is mathematically identical to the "Proposed Estimator" of (Huso, 2011, §3.2, $p.$7). This estimate always exceeds Pollock's estimator $\widehat{M}_{ij}^{\mathrm{P:E}}$ (7c) for exponential persistence

$$\widehat{M}_{ij}^{\mathrm{H}} \ge \widehat{M}_{ij}^{\mathrm{P:E}} = \frac{c_{ij}I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}\left[1-e^{-I_{ij}/\hat{t}_{ij}}\right]}. \tag{10}$$

The two never differ by more than one percent, and coincide whenever $I_{ij} < 4.6\hat{t}_{ij}$, so $\widehat{M}_{ij}^{\mathrm{H}}$ may be viewed simply as a complicated way of expressing $\widehat{M}_{ij}^{\mathrm{P}}$ for exponential persistence times. Huso's estimator will be valid and nearly unbiased under the assumptions:

$\mathrm{A}_1^{\mathrm{H}}$: Each period begins with no discoverable carcasses.

$\mathrm{A}_2^{\mathrm{H}}$: Carcass persistence times have exponential distributions.

The estimation equations considered here –

$$
\begin{aligned}
\widehat{M}_{ij}^{\mathrm{EJ}} &= \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}} && (1)\\
\widehat{M}_{ij}^{\mathrm{S}} &= \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}}\left[\frac{e^{I_{ij}/\hat{t}_{ij}} - 1 + \hat{s}_{ij}}{e^{I_{ij}/\hat{t}_{ij}} - 1}\right] && (3)\\
\widehat{M}_{ij}^{\mathrm{P}} &= \frac{C_{ij}}{\hat{p}_{ij}\hat{s}_{ij}} && (6)\\
&= \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}}\left[1 - e^{-I_{ij}/\hat{t}_{ij}}\right]^{-1} \quad \text{for exponential persistence} && (7c)\\
&= \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}} P\left(\frac{1}{\alpha}, \left[\Gamma\left(1 + \frac{1}{\alpha}\right) I_{ij}/\hat{t}_{ij}\right]^{\alpha}\right)^{-1} \text{for Weibull persistence} && (8c)\\
\widehat{M}_{ij}^{\mathrm{H}} &= \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}\left[0.99\,\Lambda\left(1 - e^{-I_{ij}/\hat{t}_{ij}}\right)\right]} \approx \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}}\left[1 - e^{-I_{ij}/\hat{t}_{ij}}\right]^{-1} && (9)
\end{aligned}
$$

– are all intended to adjust for the gross underestimation of mortality M_{ij} by simple carcass counts C_{ij}. Each of them relies on the Common Assumptions A1–A4 (see p. 31) and each is a valid estimator of M_{ij} under some additional assumption ($\mathrm{A}_1^{\mathrm{EJ}}$, $\mathrm{A}_1^{\mathrm{S}} - \mathrm{A}_3^{\mathrm{S}}$, $\mathrm{A}_1^{\mathrm{P}}$ and $\mathrm{A}_1^{\mathrm{H}}$ & $\mathrm{A}_2^{\mathrm{H}}$, respectively).

Discussion

The Figures

Figures 16-19 illustrate the models for fatality and removal implicit in the estimators. Each figure shows simulated counts $G_{ij}(t)$ of carcasses in the area as solid black stair-step curves that increase by one with each new fatality, decrease by one with each scavenger removal, and decrease by C_{ij} at the end of the j^{th} interval upon the discovery and removal of C_{ij} carcasses by the search teams (each C_{ij} is indicated by a red downward arrow). In Figures 16–18, undiscovered carcasses remain present and may be discovered by later searches. To simplify comparison by focusing attention on what is different about the models (and not just random variation), the same fatality and removal times are used for each, so the functions $G(t)$ are identical in Figures 16-18. (In Figure 19, necessarily featuring different removal times, carcasses are removed following searches.)

The mean value functions $g_{ij}(t)$ implicit in the models are shown as solid blue curves, beginning each interval at an open circle and ending it at a filled circle (these overlap in Figure 16, where $g_{ij}(t)$ takes a constant value). Simulations and mean value calculations all use a daily fatality rate of $m_{ij} = 3\mathrm{d}^{-1}$, so $10\mathrm{d} \times 3\mathrm{d}^{-1} = 30$ fatalities would be expected in each interval, or 120 overall (113 appeared in the simulation). Rate of removal by scavengers was $r_{ij} = 0.25\mathrm{d}^{-1}$, so persistence times averaged $t_{ij} = 1/r_{ij} = 4\mathrm{d}$ and, at steady-state, $m_{ij}t_{ij} = 3\mathrm{d}^{-1} \times 4\mathrm{d} = 12$ carcasses would be present. The search teams, whose proficiency was $s_{ij} = 70\,percent$, discovered 35 carcasses in the four intervals of the simulation.

Comparing the Estimators

The estimators fall into two groups. Estimators $\widehat{M}_{ij}^{\mathrm{EJ}}$ and $\widehat{M}_{ij}^{\mathrm{S}}$ each assume that some or all carcasses remain across searches, and that undiscovered carcasses from earlier time periods are removed or discovered at the same rates as fresh carcasses. In contrast, estimators $\widehat{M}_{ij}^{\mathrm{P}}$ and $\widehat{M}_{ij}^{\mathrm{H}}$ assume that each search period begins with no discoverable carcasses. For a fixed searcher proficiency and carcass persistence rate under the same site-specific characteristics, the ordering of the estimators is consistently:

$$\widehat{M}_{ij}^{\mathrm{EJ}} < \widehat{M}_{ij}^{\mathrm{S}} < \widehat{M}_{ij}^{\mathrm{P}} \le \widehat{M}_{ij}^{\mathrm{H}} \tag{11}$$

for exponential persistence probability distributions. Note that then $\widehat{M}_{ij}^{\mathrm{H}} \equiv \widehat{M}_{ij}^{\mathrm{P}}$ unless $I_{ij} > 4.6\hat{t}_{ij}$, in which case they differ by at most 1.01 percent.

Choosing an Estimator

Which group of estimation equations is more appropriate for a particular species and experimental design— one of those ($\widehat{M}_{ij}^{\mathrm{EJ}}$, $\widehat{M}_{ij}^{\mathrm{S}}$) in which carcasses from earlier periods persist? Or one of those (like $\widehat{M}_{ij}^{\mathrm{P}}$) in which each period is assumed to begin with no carcasses present?

Imagine sending two search teams with the same proficiency (say, 50 percent) into the same area in which, say, 20 carcasses are present, one after the other. The first team should find about 50 percent × 20 = 10 carcasses, on average — but what would the *second* team find?

If they would be expected to find nothing, because all the discoverable carcasses would have been removed by the first team, then the Erickson & Johnson and Shoenfeld estimators ($\widehat{M}_{ij}^{\mathrm{EJ}}$, $\widehat{M}_{ij}^{\mathrm{S}}$) would not be appropriate. Both would underestimate M_{ij} by a factor of about $\left[1 - e^{-I_{ij}/\hat{t}_{ij}}\right]$, leading to a negative bias.

If they would find about 50 percent × 10 = 5 carcasses (half those not found by the first team), then Pollock's and Huso's estimators would be inappropriate. Both would overestimate M_{ij} by a factor of about $\left[1 - (1 - \hat{s}_{ij})e^{-I_{ij}/\hat{t}_{ij}}\right]^{-1}$, leading to a positive bias.

Bias from Inappropriate Equation

These biases are apparent in the figures. In Figure 16, the stair-step simulated curves $G_{ij}(t)$ typically lie well below the Erickson & Johnson mean function $g_{ij}(t) \equiv g_{ij}^{\infty}$, and their endpoints (the filled squares) lie below g_{ij}^{∞} on average, leading to underestimation (by −5.9 percent on average, for the parameters in this simulation). In Figure 18, the stair-step simulated curves typically lie above Pollock's mean function $g_{ij}(t)$ and the period endpoints, the filled squares, lie above $g_{ij}(t)$ on average, leading to overestimation (but only by +2.5 percent for the parameters used here). In Figure 17, the simulated curves $G_{ij}(t)$ coincide on average with Shoenfeld's mean function $g_{ij}(t)$, leading to accurate estimates. Figure 19 shows the degradation-based estimator $\widehat{M}_{ij}^{\mathrm{P}} = \widehat{M}_{ij}^{\mathrm{H}}$ with a simulation consistent with their assumptions (exponential persistence times and carcass removal following searches), so there is no bias.

The biases would be larger with more frequent searches, possibly considerably larger. Daily searches, for example, with the same residence time $t_{ij} = 4\mathrm{d}$ and searcher proficiency $s_{ij} =$

70 $percent$, would lead to −71.1 percent bias for estimator $\widehat{M}_{ij}^{\mathrm{EJ}}$ and +30.5 percent bias for $\widehat{M}_{ij}^{\mathrm{H}}$ or $\widehat{M}_{ij}^{\mathrm{P}}$, while $\widehat{M}_{ij}^{\mathrm{S}}$ would remain unbiased.

In the scenario of Figure 19, where undiscovered carcasses remain undiscoverable as if they were removed, Pollock's estimator (and Huso's which is identical) is unbiased while Shoenfeld's and Erickson/Johnson's underestimate M_{ij} by factors of $\left[1-(1-s_{ij})e^{-I_{ij}/t_{ij}}\right]^{-1}$ and $\left[1-e^{-I_{ij}/t_{ij}}\right]$, respectively, for biases of −2.46 percent and −8.21 percent, respectively, with the 10-day search periods and 4-day persistence assumed here. For daily searches these biases would grow to −23.6 percent and −77.9 percent, respectively.

Bias Affecting All Equations

Each of the estimation formulas is based on an expression of the expected carcass count $\mathrm{E}\left[C_{ij}\right]$ as a function of the fatality count M_{ij} and some other variables, such as the average persistence time t_{ij} and the search team's proficiency s_{ij}. An estimator is then constructed by solving this equation for M_{ij} as a function of $\mathrm{E}\left[C_{ij}\right]$.

Consider, for example, estimator $\widehat{M}_{ij}^{\mathrm{EJ}}$ of Eqn. (1), derived from Equation (2), *i.e.*, the relation

$$\mathrm{E}\left[C_{ij}\right]I_{ij} = M_{ij}s_{ij}t_{ij}.$$

If both s_{ij} and t_{ij} are uncertain or variable, perhaps because they depend on covariates (grass height, etc.) that themselves are variable or perhaps simply because they must be estimated from data, then there is still a linear relation for the expectations

$$\mathrm{E}\left[C_{ij}I_{ij}\right] = \mathrm{E}\left[M_{ij}\hat{s}_{ij}\hat{t}_{ij}\right]$$

for independent unbiased estimators $\hat{s}_{ij}$ of s_{ij} and $\hat{t}_{ij}$ of t_{ij}. Bias enters, however, when one makes the *non*-linear transformation of solving for M_{ij}:

$$M_{ij} \approx \widehat{M}_{ij} = \frac{C_{ij}I_{ij}}{\hat{s}_{ij}\hat{t}_{ij}}.$$

Because the function *x* ~~>1/*x* is convex (its graph curves upward), the expectation of $1/\hat{s}_{ij}$ will *always* exceed $1/\mathrm{E}\left[\hat{s}_{ij}\right]$, and that of $1/\hat{t}_{ij}$ will always exceed $1/\mathrm{E}\left[\hat{t}_{ij}\right]$, so uncertainty or variability in s_{ij} and t_{ij} will lead each of these estimators to *over*estimate fatality to some extent, with $\mathrm{E}[\widehat{M}_{ij}] > M_{ij}$. But how large is this positive bias?

If a positive random variable X has a log-normal distribution (commonly used to model uncertain positive quantities such as s_{ij} or t_{ij}) with mean $\mathrm{E}\,[X]=M$ and variance $\mathrm{V}[X]=V$, then $1/X$ also has a log-normal distribution, but the mean is *not* $1/M$. It is always larger:

$$\mathrm{E}\,\frac{1}{X} = \frac{1}{M}\left[1+\frac{V}{M^2}\right],$$

more than $1/M$ by a fraction V/M^2.

Thus if $\hat{s}_{ij}$ is an unbiased estimator of s with standard error ϵ, then $(1/\hat{s}_{ij})$ is a positively biased estimator of $(1/s_{ij})$ with bias given by:

$$\mathrm{E}\left[1/\hat{s}_{ij}\right] = (1/\hat{s}_{ij})\left[1 + \left(\epsilon/s_{ij}\right)^2\right]$$

with a similar formula for t_{ij}. If s_{ij} and t_{ij} are known to within a small proportional error, *i.e.*, if their standard errors are small fractions of their values, then little bias is introduced; if not, then more sophisticated statistical approaches may be warranted.

Variability

All the estimators considered here are of the form $\widehat{M}_{ij}$=κC_{ij}, proportional to the carcass count with a proportionality coefficient κ which will depend on I_{ij}, $\hat{s}_{ij}$, $\hat{t}_{ij}$, and perhaps other quantities. The value of κ is determined by solving for M_{ij} an equation for the expected number $\mathrm{E}[C_{ij}] \propto M_{ij}$ of carcasses counted. The resulting *variability* of the estimators $\widehat{M}_{ij}$ can be quite large.

Because C_{ij} has a Poisson distribution under the models justifying all four of the estimators under consideration, and Poisson random variables have variance equal to their means, the variance of each such estimator $\widehat{M}_{ij}$=κC_{ij} will be $\kappa^2 V[C_{ij}] = \kappa^2 \mathrm{E}[C_{ij}] = \kappa \mathrm{E}[\widehat{M}_{ij}]$. Even an unbiased estimator $\widehat{M}_{ij}$ with expected value $\mathrm{E}[\widehat{M}_{ij}] = M_{ij}$ will have variance κM_{ij} that may be quite large. For counts high enough to justify a central limit approximation, one should expect typical estimation errors to be on the order of $\sqrt{\kappa M_{ij}}$,

$$\left|\widehat{M}_{ij} - M_{ij}\right| \leq 1.645\sqrt{\kappa M_{ij}} \approx 1.645\sqrt{\kappa \widehat{M}_{ij}}$$

with probability about 90 percent (and similar formulas for other quantiles). For counts C_{ij} too small to justify the central limit theorem, the Anscombe transformation

$$Z := 2\sqrt{C_{ij} + 3/8} \sim No\left(2\sqrt{c_{ij} + 1/8}, 1\right)$$

for $c_{ij} := \mathrm{E}[C_{ij}]$ (Anscombe, 1948) leads to reliable interval estimates for M_{ij} for counts as low as $C_{ij} \geq 4$. Exact Poisson confidence intervals are available for all counts $C_{ij} \geq 0$.

For example, at the end of the second period of the simulation shown in Figure 17, $C_{i2} = 11$ carcasses were counted. With $s_{i2} = 0.7$ and $t_{i2} = 4$ estimated perfectly, Shoenfeld's estimator is $\widehat{M}^{s}_{i2} = \kappa C_{i2}$ with

$$\kappa = \frac{I_{i2}}{\hat{s}_{i2}\hat{t}_{i2}}\left[\frac{e^{I_{i2}/\hat{t}_{i2}} - 1 + \hat{s}_{i2}}{e^{I_{i2}/\hat{t}_{i2}} - 1}\right] = \frac{10}{0.7 \times 4}\left[\frac{e^{2.5} - 1 + 0.7}{e^{2.5} - 1}\right] = 3.795$$

so a 90 percent Central Limit interval estimate is $\widehat{M}^{s}_{i2} = 41.745 \pm 10.6 = [31.145, 52.345]$. The more accurate Anscombe approximation is [24.21, 66.31] and the exact Poisson interval is [23.41133, 69.09737]. In the simulation $M_{i2} = 30$ fatalities occurred, exactly the expected number $I_{i2} m_{i2} = 10 \times 0.3 = 30$, but the 90 percent interval for this estimator ranges from -21.9 percent below the true value to +130.3 percent above it.

What if the Common Assumptions Fail?

Common Assumption A_1, that all fatalities lead to carcasses within the study area, is usually false because some carcasses may fall outside the designated study area, and some birds may be crippled but able to make it outside the study region. If unaddressed, this "crippling bias" would lead to underestimation of fatality. It is usually addressed simply by estimating the probability π_{ij} that a fatality will lead to a carcass in the study area, then scaling any of the estimators ($\widehat{M}_{ij}^{\mathrm{EJ}}$, $\widehat{M}_{ij}^{\mathrm{S}}$, $\widehat{M}_{ij}^{\mathrm{P}}$, $\widehat{M}_{ij}^{\mathrm{H}}$) by a factor of $1/\hat{\pi}_{ij}$.

Common Assumption A_2 that all counted carcasses in the study region arise from encounters with the indicated turbine, is only approximately correct. Fatalities are usually assumed to be turbine related unless there is evidence to the contrary, but because the fatality rates from other causes are thought to be small enough this is not believed to lead to significant over-counting. A related problem is that some encounters with turbines may dismember a carcass into multiple pieces deposited in multiple discrete locations with the search area. Searchers attempt to prevent double-counting by matching parts, but this process is subject to error.

Search areas are generally established by rules of thumb, because of incomplete experimental data to suggest the true area of influence a turbine exerts, and may overlap. This could lead to misattribution, violating either A_1 or A_2.

Common Assumption A_3, that carcasses arrive uniformly over the time interval, will not be satisfied exactly. Actual fatality rates will vary over time with diurnal patterns, weather dependence, and other factors. If there are significant *trends* in fatality over the time period then this would affect each of the estimators, but haphazard variation on a rapid time-scale compared to search intervals will not. Some birds and bats have migratory behavior that may lead to widely differing rates from year to year or period to period, but if search intervals I_{ij} are short compared to migratory time scales then A_3 can still apply separately on each interval, but fatality and removal rates may vary for different time periods j.

Common Assumption A_4, that quantities are either constant or are sufficiently well represented by their averages, is also false. Both discovery by search teams and removal by scavengers are more difficult in areas or time periods within the study region where and when grass is taller, or light less available. Fortunately, these too are somewhat compensatory, but more elaborate modeling would be required to remove their effects entirely. Estimating s_{ij} and t_{ij} by imperfect estimators $\hat{s}_{ij}$ and $\hat{t}_{ij}$ does introduce some bias for all the estimators considered here, a rather technical issue.

Some estimators ($\widehat{M}_{ij}^{\mathrm{S}}$, $\widehat{M}_{ij}^{\mathrm{H}}$, and sometimes Pollock's $\widehat{M}_{ij}^{\mathrm{P}}$) also assume that carcass persistence times have exponential distributions. This distribution features a constant "hazard rate," so its use implies that carcasses remain equally attractive to scavengers over time. Evidence suggests that this is false. Over time carcasses do deteriorate, with two effects: they become less attractive to scavengers, reducing the removal rate r_{ij}; and they become more difficult for search teams to discover, reducing the proficiency s_{ij}. These two effects are somewhat compensatory, the first increasing and the second decreasing estimates of M_{ij}. If degradation is sudden and thorough enough it may be viewed simply as another form of removal by scavengers, maintaining validity for all the estimators, but if degradation is sufficient to deter scavengers but not enough to affect discovery that would lead to a positive bias.

Extensions

Each of the estimation approaches may be embellished to allow the rates of removal, fatality, or discovery to depend on meteorological, topographical, or other covariates, taken to be constant covariates for each turbine i and time interval j, at the cost of a considerable increase in computational complexity.

Coupled Degradation Models

In each of the models considered above the removal process and discovery are treated as "independent," even for those underlying estimators $\widehat{M}_{ij}^{\mathrm{P}}$ and $\widehat{M}_{ij}^{\mathrm{H}}$ that feature degradation. If in fact carcasses differ in their appeal to scavengers and the ease with which they are detected by search teams, and if the same carcasses that are easy for search teams to discover are those that are rapidly removed by scavengers, then each of these estimators will be biased. Each on average will underestimate M_{ij}, because the easily discovered carcasses will have been removed preferentially. Equation (12) shows an extension of Pollock's Weibull persistence equation (8c) for the most extreme case, where the removal and discovery processes are "coupled" in the sense that those carcasses with the longest persistence times are precisely those most difficult for search teams to discover:

$$\widehat{M}_{ij}^{\mathrm{x}} = \begin{cases} \dfrac{C\, I/\hat{t}_{ij}}{P\left(\frac{1}{\alpha}, \left[\Gamma\left(1+\frac{1}{\alpha}\right) I/\hat{t}_{ij}\right]^{\alpha}\right) - \left(1-\hat{s}_{ij}\right) I/\hat{t}_{ij}} & \hat{s}_{ij} > 1 - e^{(I/\hat{t}_{ij})^{\alpha}} \\ \dfrac{C\, I/\hat{t}_{ij}}{P\left(\frac{1}{\alpha}, \left(1-\hat{s}_{ij}\right)\right) - \alpha\left(1-\hat{s}_{ij}\right)\left[-\log\left(1-\hat{s}_{ij}\right)\right]^{1/\alpha}} & \hat{s}_{ij} \leq 1 - e^{(I/\hat{t}_{ij})^{\alpha}} \end{cases} \qquad (12)$$

Intermediate cases between independence (8c) and coupling (12) are possible too. More details are presented in Appendix B along with a more elaborate model in which:

- Scavenger removal rates r_{ij} and search team discovery rates s_{ij} are allowed to depend on extrinsic covariates (grass height, for example) and on carcass age (hence persistence times will not have exponential distributions and counts may not be Poisson);
- Mortality rates m_{ij} need not be constant (seasonal and diurnal patterns may be explored),
- Hierarchical structure exploits the similarities expected for data from different but comparable time periods or search regions.

Each of the models underlying the estimators considered above can be expressed as a special case of that new model. Parameter estimation for the new model is more computationally intensive than the estimation formulas given here, however, and will require more extensive data collection, such as that described in Appendix B, which may not be available at all sites of interest.

CHAPTER 4: Study Findings and Recommendations

CalWEA's study offers several lessons with implications for the experimental designs and field monitoring recommendations provided in the Guidelines. The key findings, elaborated below, can be summarized under the following general statements:

(1) Searcher proficiency is shown to be time-dependent.
(2) Searcher proficiency is site- and species-specific.
(3) Searcher proficiency is lower for bats than for birds.
(4) Carcass persistence is a time-dependent process.
(5) Small birds have a lower time-dependent persistence than bats.

In addition, CalWEA's analysis of the Guidelines' recommended fatality estimation equation (Pollock) and three other prominent estimators (Erickson & Johnson, Shoenfeld, and Huso) finds that:

(6) All four of the equations reviewed introduce some bias.
(7) The equations can be distinguished by their underlying assumption about whether undiscovered, unremoved carcasses remain "discoverable" in subsequent searches.
(8) For all four equations, length of search interval relative to mean persistence time is a key determinant of bias.

These findings have implications for pre- and post-construction monitoring activities, discussed below along with a recommendation for development of an improved estimating equation that takes into account findings 6-8, above.

Summary of Field Study Findings

Searcher Proficiency Shown to be Time-dependent

This study is the first to document quantitatively the long-term relationship between carcass age and the ability to detect the carcass. The implications for this issue are large, and will influence survey methods, the number of carcasses used during detection trials, and the approach to conducting pre-survey detection trials.

Searcher Proficiency is Site- and Species-specific

The magnitude of the searcher proficiency rate will be site specific, and will be a function of environmental and topological variables. In this study, searcher proficiency was significantly related to vegetation height. In addition to showing that searcher proficiency is a time-dependent process, Figures 14 and 15 clearly indicate that the shape of the searcher proficiency curves (with time and vegetation height) differ for birds and bats, and for small and large birds.

Searcher Proficiency is Lower for Bats than for Small Birds

A key contribution of this study is the findings associated with bats. Statistics derived from this study indicate that, on average, searcher proficiency of bats is roughly half that of small birds.

Large birds in this study were detected approximately 70 percent of the time. From a specific carcass perspective, approximately 30 percent of all small birds in the study were detected at least once, while only 19 percent of the bats were detected at least once.

The above rates for small birds are consistent with published literature values. For bats, however, the incorporation of time-based functions of searcher proficiency will have a significant impact on the resulting bat fatality estimation.

In this study, the searcher proficiency for small birds and bats was found to be similar after approximately 25 days, with the largest difference seen initially after carcass placement when the carcasses were fresh. An approximate 15 percent difference is seen between searcher proficiency in birds and bats with fresh carcasses. The searcher proficiency for birds and bats approached 2 percent after 30 days. This finding has implications for interval length in post-monitoring studies, where this study points to shorter intervals in order to maximize the chance of detecting a carcass on the ground.

Carcass Persistence is a Time-based Process

For small birds, an initial 10-15 percent loss in total numbers can be expected in the first few days after first appearance. For bats, the initial loss rate is smaller, ranging from zero to approximately 6 percent. Again, this finding for bats may not be expected based on the current literature. In this study, the persistence probability for small birds was 50 percent at approximately 10 days, and less than 20 percent after 40 days. For bats, however, the persistence probability was approximately 50 percent at 25 days, and did not drop below 20 percent over the course of the study.

Carcass persistence curves can be a function of seasonal effects. Persistence curves for both small birds and bats differ over the course of the study timeframe.

Small birds have lower time-dependent persistence than bats

Based on this study, bats persist longer on the field than birds. While the relative time-process of persistence will be site-specific (at other sites the predator population may prefer bats), the finding of an increased persistence of bats relative to birds has implications for the ability of estimating equations to work well without a well-defined and rigorously tested persistence curve for bats. Coupling the longer persistence with the lower detection rates of bats as compared to birds could lead to gross error in the expected fatality of bats if new bat-specific estimating equations are not fully developed and tested. Indeed, because bats persist for relatively long periods and are difficult to see on the ground, the interaction of searcher bias and detection proficiency plays a significant role in accurately estimating bats. In particular for bats, long-term field trials rigorously designed to generate time-based searcher detection proficiency and carcass persistence rates will be critical to accurate estimation of bat fatality.

Carcass persistence is best fit with a Weibull distribution

The assumption of an exponential decay function in many existing equations was not directly tested in this study. A two-parameter Weibull function, which provides greater flexibility than the simple exponential assumptions, is shown to work well within the study conditions. As noted in Chapter 3, the constant hazard assumption of the exponential function may not be realistic if older carcasses appear less attractive to scavengers, as shown in this study. The Weibull family of functions can be used to model carcass persistence without the assumption of constant hazard.

Summary of Estimating Equations Analysis

Existing fatality estimating equations assume that fatalities (and the corresponding occurrence of carcasses in a search plot) are randomly distributed over time. Because the experimental design of the CalWEA study did not allow for carcasses to be placed at random temporal intervals, direct calculation and comparison of the estimating equations against the known true number of birds and bats was not an appropriate test. Instead, equation properties and implicit assumptions were evaluated mathematically and the findings assessed in light of the findings from the field study.

The Existing Estimators All Introduce Some Bias

The CalWEA field study's finding that both searcher proficiency and carcass removal are time-dependent processes violates a common assumption of the four existing estimators that all carcasses are independent. This could easily be the case in this study where some carcasses specifically persisted and were not detected by the end of the study, indicating a lack of independence among the carcasses with respect to the two time-based processes.

If both searcher proficiency (s_{ij}) and mean persistence time (t_{ij}) are uncertain or variable, perhaps because they depend on covariates (grass height, etc.) that themselves are variable or perhaps simply because they must be estimated from data, then there is still a linear relation for the expectations for independent unbiased estimators $\hat{s}_{ij}$ of s_{ij} and $\hat{t}_{ij}$ of t_{ij}. Bias enters, however, when they are made the *non*-linear transformation of solving for M_{ij}.

Another common assumption, that quantities are either constant or are sufficiently well represented by their averages, is also false. Both discovery by search teams and removal by scavengers and weathering are more difficult in areas or time periods within the study region where and when grass is taller, or light less available. Fortunately, these too are somewhat compensatory, but more elaborate modeling would be required to remove their effects entirely. Estimating s_{ij} and t_{ij} by imperfect estimators $\hat{s}_{ij}$ and $\hat{t}_{ij}$ does introduce some bias for all the estimators considered here, a rather technical issue sketched in Chapter 3.

Key Assumptions Distinguish the Estimators

Each of the equations evaluated contains implicit assumptions pertaining to the nature of the rate of bird/bat fatality during the search interval, the distribution of carcass persistence times, and whether carcasses that persist from one search interval to the next are considered "discoverable" during a subsequent search. These distinguishing assumptions are summarized in Table 9.

Table 9: Key Assumptions Distinguishing Estimators Reviewed

Equation	Key Assumptions
Erickson & Johnson (1998)	A_1^{EJ}: The system is in equilibrium at each search. $I_{ij} \gg t_{ij}$,
Shoenfeld (2004)	A_1^{s}: Carcass persistence times have exponential distributions. A_2^{s}: All carcasses (both old and new) have the same probabilities of discovery s_{ij}. Undiscovered carcasses are no harder or easier to find than those that were discovered— *i.e.*, discovery failures are entirely random. A_3^{s}: The lengths I_{ij}, rates of mortality m_{ij} and removal r_{ij}, and the proficiencies s_{ij} are approximately constant over consecutive time intervals.
Pollock (2007)	A_1^{P}: Each period begins with no discoverable carcasses
Huso (2011)	A_1^{H}: Carcass persistence times have exponential distributions. A_2^{H}: Each period begins with no discoverable carcasses.

Source: Dr. Robert Wolpert

An important contribution of this analysis is the concept of "bleed-through" – the idea that every carcass not discovered and removed in a search, and does not persist due to scavenging, weathering, or other natural processes, remains for possible discovery in later searches. Both Erickson-Johnson and Shoenfeld's estimators assume 100 percent bleed-through. Huso's estimator assumes zero percent bleed-through – *none* of the carcasses not removed (by searchers or scavengers) are *ever* discovered in subsequent searches. Pollock's estimator uses an "average probability a carcass is unremoved until the search" (p_{ij}) rather than the more commonly used "mean persistence time" (t_{ij}). But as with Huso's estimator, Pollock's implicit assumption is that each period begins with no discoverable carcasses ("old" carcasses are never discovered).

Length of Search Interval Relative to Persistence Time is a Key Determinant of Bias

When search intervals are long with respect to persistence times, the influence of this "carcass at the beginning of the search interval" assumption is minimized and the estimators are nearly unbiased and provide very similar answers. However, for very short search intervals (a growing tendency in the wind industry), the bias in some equations can be large, and the equations can provide very different results. Figures 20-21 illustrate this point, showing the range of bias in fatality estimates obtained using the various estimators with different search intervals and bleed-through rates (theta = 0, 1 or 0.5), for given removal rates α = 1 and 0.5.

Figure 20: Comparison of Bias in Estimators at Various Search Intervals and "Bleed Through" (θ) Assumptions with Removal Rate α= 1

	56 days	28 days	14 days	7 days	2 days
Erickson θ = 0	-2.4%	-15.5%	-39.3%	-62.7%	-87.5%

Source: Dr. Robert Wolpert

The degree of bias among the equations is a function of many issues but, in all cases, it is a function of the inherent assumptions underlying the equation characteristics. Even when biased, if search intervals are *long* relative to mean persistence times, all four estimators give about the same answers. But if search intervals are *short* relative to mean persistence times, large differences among the equations are possible. In fact, it is very possible that, with short intervals, the results of the equations could differ by a factor of 3 or 4. For example, Shoenfeld's and Huso's estimators will differ by a factor of 3 or 4 or so if the search proficiency is 25 percent or 33 percent or so, because Huso assumes zero percent bleed-through and Shoenfeld assumes 100 percent bleed-through.

Conclusions and Recommendations

CalWEA's study provides new insights that could enhance the existing methods and procedures found in the Guidelines and other pre- and post-construction fatality monitoring guidelines used in the United States and internationally. Four major implications of this work and the corresponding recommendations are outlined here.

(1) Traditional fatality estimators do not account for time-dependence of carcass persistence and searcher proficiency, or for "bleed-through."

Recommendation: Use the proposed new Partial Periodic Estimator and integrated detection probability trial method (proposed in Appendices A and B, respectively).

(2) Traditional estimators can have high degrees of bias depending on the search interval, mean persistence, and bleed-through rate (theta) of the field data collected.

Recommendation: Do not use traditional estimators in conditions that produce levels of bias that are unacceptable for the intended purpose. Caution is particularly warranted where short search intervals have been used.

(3) Use of traditional estimators has resulted in an unknown degree of bias in the literature.

Recommendation: Carefully consider the value of metrics like "industry average" before applying them in policy or project-specific decisions.

(4) Previously generated fatality estimates used for project evaluation or broader purposes could be recalculated using the proposed new Partial Periodic Estimator, provided the key input variables (search interval, mean persistence, etc.) can be collected from the original studies and reasonable assumptions made about searcher proficiency probability distributions and theta values.

> *Recommendation:* Going forward, use a standardized approach to generate unbiased project-specific results that may be compared with each other, and to generate meaningful and unbiased industry averages and totals.

These implications and recommendations are briefly discussed here.

Current estimators do not account for time-dependent processes and "bleed-through."

Detection probability is now known to be sensitive to time-dependent processes of carcass persistence, searcher proficiency, and bleed-through (theta), and that the traditional fatality estimators do not account for these influences. Therefore a new Partial Periodic Estimator (Appendix A) and an integrated detection probability field-trial methodology (Appendix B) are proposed and recommended that incorporate:

- Trials for searcher proficiency & carcass removal rates conducted simultaneously (vs. independent trials)

Further, the Guidelines on these issues are recommended to be revisited.

Care must be taken to avoid unacceptable bias when using current fatality estimators.

The four traditional fatality estimators reviewed (Pollock, Erickson & Johnson, Shoenfeld and Huso) are now shown to have high degrees of bias depending on the search interval, mean persistence, and the proportion of bleed-through (theta) occurring in the field. Therefore these estimators are not recommended for use in conditions that produce unacceptable levels of bias (see Figures 20-21) unless biases can be corrected.

Note that "unacceptable" bias depends on circumstance and degree of accuracy needed.

- The inaccuracy of an estimate for a specific project may or may not be of consequence.
- The importance of accuracy or just precision depends on the sensitivity of the species, regulatory requirements, etc.

While individual project results are likely to be inaccurate, precise comparisons internal to a given project may still be useful provided the project studies are consistent with each other.

Use of previous study estimates

Previously generated study estimates can be used with some confidence in decision making where a persistence trial has produced a reliable mean value, providing that mean persistence time is shorter than the search interval (noting also that, in some cases, mean persistence will also have to be recalculated because of some common errors in methods of calculating this mean). If the persistence time is longer than the search interval, the estimate will be unreliable. If the mean is comparable to the search interval, the estimate will vary in the range of 30-40 percent.

Caution should be taken with metrics such as "Industry Average"

The findings in this project highlight the degree of difficulty that occurs when comparing mortality estimates among individual studies, particularly when the individual studies are not conducted with a standardized survey design. A number of factors make between-study results difficult, and also negate the ability to compare the results from a single study to an industry-wide average. For example, the following elements can negate the ability to compare mortality results on a national or state-wide basis: (1) differing approaches to treating the resulting survey data (*e.g.*, compiling data across individual turbines), (2) differing approaches to calculating inputs to the estimating equations (*e.g.*, estimation of mean persistence time), (3) the use of different equations, and (4) inconsistent survey design and field methods. Any industry average, therefore, will reflect a large variation among sites not due to variation in mortality, but due to the specific methods used to generate the mortality values. Therefore, a standardization of methods used to evaluate wind facility impacts is recommended, based in part on the findings of this report.

Considerable caution is in order when comparing individual project estimates to industry averages, given the possible level of bias in, and lack of comparability among, each of the source studies that are used to calculate the industry average. Similar cautions are in order when considering national total mortality figures.

Future Research

The results and findings of this study provide insight into needed changes in current monitoring practices and fatality estimation procedures at wind facilities. The existing estimating equations could be enhanced and improved with the addition of time-dependent processes for searcher proficiency and carcass persistence that are a function of environmental conditions. Appendix A presents a proposed new equation that incorporates these terms, and Appendix B outlines the key components for detection probability trial survey methods to support the proposed new estimator. Field testing the new estimating equation and protocols was beyond the scope of this study and report.

The Altamont study site provided a unique venue for studying fatality under changing conditions, and while all of the findings of this study will not directly translate to other sites, the general principles and findings should be applicable. The major findings of this study should hold generally for all wind facilities. However, the degree to which the vegetation height, time-based searcher efficiency, and other factors that were found influential in this study are transferable to other locations and conditions is explicitly unknown. Therefore, additional studies may provide insights on fatality estimation as a function of topographical, climatological, and environmental conditions.

APPENDIX A:
A New Equation for Estimating Avian Mortality Rates

A Partially Periodic Equation for Estimating Avian Mortality Rates

Robert L Wolpert

October 6, 2012

Abstract

A key issue in assessing the environmental impact of wind plants for electrical power generation is the rate of mortality of birds and bats caused by collisions with turbines. The direct approach of counting and removing carcasses near a turbine facility at designated time intervals must be corrected in some way for the effects of removal by scavengers, detection failure, and other systematic biases. A number of authors have proposed estimation formulas intended to adjust for these, based on somewhat different assumptions about the underlying processes.

One significant issue on which these authors differ is whether or not bird carcasses present but *not* discovered and removed in the search ending one time interval, might possibly be discovered and counted in the search ending a later interval. The "periodic" estimator proposed by Shoenfeld (2004), for example, is based on a model in which any undiscovered carcasses may be found in later searches, while the aperiodic estimators proposed by Pollock (CEC, 2007, Appendix F) and by Huso (2011) are both based on the assumption that each interval begins with no discoverable carcasses.

We present a unified "partially periodic" structure that encompasses all of these estimators, in which a specified fraction of undiscovered carcasses remain discoverable in future searches. It includes that of Shoenfeld and those of Pollock and of Huso as special cases in which that fraction is 100% or 0%, respectively. The proposed estimator also accommodates arbitrary removal time distributions, avoiding the unrealistic assumption of exponential removal distributions implicit in the estimation formulas of Shoenfeld and Huso.

1 Introduction

The data we consider will be repeated counts of bird or bat carcasses made in designated search areas near each of several wind turbines. Denote by C_{ij} the count of carcasses in the designated area near the jth wind turbine by a Search Team at the end of the ith time interval, of length I_{ij} days, and by s_{ij} the search proficiency (discovery probability for a carcass present at the time of the search) and by t_{ij} the average length of time (in days) before a new carcass is removed by scavengers.

For the special case of exponentially-distributed removal times, the proposed estimator (derived in Section (2.1) and generalized to arbitrary removal distributions in Section (2.2)) is:

$$\hat{M}_{ij}^{\star} = \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\ \hat{t}_{ij}} \left\{ \frac{e^{I_{ij}/\hat{t}_{ij}} - \theta(1-\hat{s}_{ij})}{e^{I_{ij}/\hat{t}_{ij}} - 1} \right\}, \tag{1}$$

where $\theta \in [0,1]$ is the fraction of undiscovered carcasses that remain discoverable in future searches. This includes as special cases each four of the estimators compared in (Wolpert, 2012; Warren-Hicks *et al.*, 2012):

Shoenfeld: For $\theta = 1$, indicating that *all* unremoved carcasses are discoverable eventually, this is exactly Shoenfeld's (Shoenfeld, 2004) estimator

$$\hat{M}_{ij}^{\text{S}} = \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\ \hat{t}_{ij}} \left\{ \frac{e^{I_{ij}/\hat{t}_{ij}} - 1 + \hat{s}_{ij}}{e^{I_{ij}/\hat{t}_{ij}} - 1} \right\}. \tag{2}$$

Thus Eqn (1) may be viewed as a generalization of Shoenfeld's estimator to *partial* periodicity, and that presented in Section (2.2) a further generalization to arbitrary removal distributions.

Pollock: Pollock's mortality estimator (CEC, 2007, Appendix F)

$$\hat{M}_{ij}^{\text{P}} = \frac{C_{ij}}{\hat{p}_{ij}\,\hat{s}_{ij}} \tag{3a}$$

depends explicitly on $\hat{p}_{ij}$, the estimated "average probability a carcass will remain until the next search". For exponentially-distributed removal times this is $\hat{p}_{ij} = [1 - e^{-I_{ij}/\hat{t}_{ij}}]\hat{t}_{ij}/I_{ij}$, so in this case $\hat{M}_{ij}^{\text{P}}$ may be expressed as

$$\hat{M}_{ij}^{\text{P:E}} = \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\ \hat{t}_{ij}} \left[1 - e^{-I_{ij}/\hat{t_{ij}}}\right]^{-1} \qquad \text{(Exponential removal)}, \tag{3b}$$

the special case $\theta = 0$ of Eqn (1).

Huso: Huso's estimator (Huso, 2011) is identical to Pollock's for exponentially-distributed removal times (unless $I_{ij} > 4.6\,\hat{t}_{ij}$, in which case $\hat{M}_{ij}^{\text{H}}$ is about 1% larger), so it too is the special case of Eqn (1) with $\theta = 0$:

$$\hat{M}_{ij}^{\text{H}} = \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\ \hat{t}_{ij}} \left[1 - e^{-I_{ij}/\hat{t}_{ij}}\right]^{-1}. \tag{4}$$

Erickson: Erickson & Johnson's estimator (Erickson *et al.*, 1998; Johnson *et al.*, 2003)

$$\hat{M}_{ij}^{\text{EJ}} = \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\ \hat{t}_{ij}} \tag{5}$$

would be (1) in the special case of $\theta = (1 - \hat{s}_{ij})^{-1}$. Note $\theta > 1$ here, because this estimator's assumption that the system is in steady-state at each search is inconsistent with the usual practice of removing carcasses upon discovery by Search Teams.

Thus each of these estimators corresponds to some specific choices for removal distribution and for the parameter θ— but maybe not the choices one would prefer on further reflection.

Some have expressed the opinion that both 100% persistence of undiscovered carcasses (*i.e.*, $\theta = 1$, as in Shoenfeld's estimator) and 100% disappearance of them (*i.e.*, $\theta = 0$, as in Pollock's and Huso's) are unrealistic, and that the truth lies somewhere in between. Also, evidence (Bispo *et al.*, 2012; Warren-Hicks *et al.*, 2012, *p.* 21ff) suggests that other survival distributions fit removal times better than exponential distributions.

2 The Model Underlying the New Partially Periodic Estimator

Suppose (as usual) that carcasses arrive in a Poisson stream with average daily rate m_{ij} and, following Shoenfeld, that the process is "periodic" in the sense that consecutive interval lengths I_{ij} (in days), mean mortality rates m_{ij} (per day), and search proficiency probabilities s_{ij} vary slowly in time— and hence do not vary with index i (though they may still differ across turbines, indexed by j). In contrast to Shoenfeld, we now assume that while all unscavenged carcasses arriving during the current period are discoverable in the search ending that period, only a fraction $\theta_j \in [0, 1]$ of those unscavenged carcasses not discovered in that search will remain discoverable for future searches.

2.1 Exponential Removal Times

The average number of discoverable carcasses at the end of any period (call it $\mathfrak{g}_1$) will be the sum of those carcasses (if any) remaining unscavenged and undiscovered by earlier searches, plus those carcasses arriving at times uniformly distributed over the present interval and remaining unremoved until its end. For the case of exponentially-distributed persistence with rate $r_{ij} > 0$, this is

$$\mathfrak{g}_1 = e^{-r_{ij} I_{ij}}\, \mathfrak{g}_0 \qquad\qquad + m_{ij} \int_0^{I_{ij}} e^{-r_{ij}(I_{ij} - s)}\, ds$$

where $\mathfrak{g}_0$ denotes the average number of discoverable carcasses at the beginning of the period. By periodicity this is $\mathfrak{g}_0 = \mathfrak{g}_1 \theta_j (1 - s_{ij})$, so

$$\mathfrak{g}_1 = e^{-r_{ij} I_{ij}}\, \mathfrak{g}_1 \theta_j (1 - s_{ij}) + \frac{m_{ij}}{r_{ij}} \left[1 - e^{-r_{ij} I_{ij}}\right].$$

Collecting terms and solving, and using $r_{ij} = 1/t_{ij}$ and $\mathsf{E}M_{ij} = m_{ij}\, I_{ij}$,

$$\mathfrak{g}_1 = \frac{\mathsf{E}M_{ij} t_{ij}}{I_{ij}} \left\{ \frac{1 - e^{-I_{ij}/t_{ij}}}{1 - \theta_j (1 - s_{ij}) e^{-I_{ij}/t_{ij}}} \right\}.$$

For searchers with proficiency s_{ij} the expected carcass count is $\mathsf{E}[C] = s_{ij}\mathfrak{g}_1$, leading to the estimator

$$\hat{M}^{\star}_{ij} = \frac{C_{ij} I_{ij}}{\hat{s}_{ij}\ \hat{t}_{ij}} \left\{ \frac{1 - \theta_j (1 - \hat{s}_{ij}) e^{-\hat{z}_{ij}}}{1 - e^{-I_{ij}/t_{ij}}} \right\}. \tag{1}$$

2.2 The General Case

The exponential distribution, commonly used for modeling removal times, features constant *hazard*— the probability of removal by scavengers in a short time interval is approximately the same constant multiple $h\,\Delta$ of the interval's length Δ, irrespective of the age t of the carcass at the start of the interval. Evidence suggests that in fact the hazard rate $h(t)$ varies with carcass age, and that (at least for large t) it decreases. Warren-Hicks *et al.* (2012) found that Weibull distributions with shape parameter $\alpha < 1$ (whose hazard $h(t)$ decreases at rate $t^{-(1-\alpha)}$) fit the observed removal times far better than exponential distributions, while Bispo *et al.* (2012) found that log normal and log logistic distributions (whose hazards decrease at rate $1/t$ for large t) or Weibull distributions fit their data better than the exponential. In this section we develop a partially-periodic estimator for arbitrary removal distributions.

Denote by $\bar{F}_j(t) = \mathsf{P}[\tau > t]$ the complimentary CDF, or survival function, for removal times $\tau \geq 0$, and by

$$Q_j(t) \equiv \mathsf{E}[\tau \wedge t] = \int_0^t \bar{F}_j(x)\, dx \tag{6}$$

the *integrated survival function* or "ISF". Clearly $Q_j(t) \leq t$ (because $\bar{F}_j(x) \leq 1$), and $Q_j(t)$ increases as $t \to \infty$ to the mean removal time $t_{ij} \equiv \mathsf{E}[\tau] = \int_0^\infty \bar{F}_j(x)\, dx$ (which may be infinite for some distributions). As before denote by $\theta_j \in [0, 1]$ the average fraction of undiscovered carcasses that remain discoverable in later searches, by s_{ij} the probability a carcass present at the time of a search will be discovered, and by m_{ij} the average daily rate of mortality.

The discoverable carcasses on the ground at any given time include "new" carcasses that arrived since the last search along with those "old" ones that arrived in earlier periods and eluded discovery by search teams. Thus if $q_j \equiv \theta_j(1 - s_{ij})$ denotes the probability that a carcass is undetected in a search and remains discoverable for future searches, then t days after the most recent search the expected number $g_j(t)$ of discoverable carcasses is the sum

$$g_j(t) = \int_0^t m_{ij} \bar{F}_j(t - s) ds + \sum_{k \geq 1} q_j^k \int_{-kI_{ij}}^{-(k-1)I_{ij}} m_{ij} \bar{F}_j(t - s)\, ds$$

of those arriving in the current period and those arriving earlier who went undetected in some number $k \geq 1$ of searches. Changing variables to $x = t - s$,

$$\begin{aligned} &= m_{ij} \int_0^t \bar{F}_j(x) dx + m_{ij} \sum_{k \geq 1} q_j^k \int_{t+(k-1)I_{ij}}^{t+kI_{ij}} \bar{F}_j(x)\, dx, \\ &= m_{ij} Q_j(t) + m_{ij} \sum_{k \geq 1} q_j^k \big[Q_j(t + kI_{ij}) - Q_j(t + (k-1)I_{ij}) \big], \end{aligned}$$

(recall $Q_j(t) := \int_0^t \bar{F}_j(x)\, dx$), a telescoping series with sum

$$g_j(t) = m_{ij}(1 - q_j) \sum_{n \geq 0} q_j^n Q_j(t + nI_{ij}). \tag{7}$$

The expected number of carcasses counted $\mathsf{E}[C_{ij}]$ will be a fraction s_{ij} of $g_j(I_{ij})$, and the average daily mortality rate is $m_{ij} = \mathsf{E}[M_{ij}]/I_{ij}$, leading to the new Partially Periodic estimator

$$\hat{M}_{ij}^{\star} = \frac{C_{ij}\ I_{ij}}{R_{ij}\ \hat{s}_{ij}} \tag{8}$$

where $R_{ij} = g_j(I_{ij})/m_{ij}$ is given by

$$R_{ij} \equiv [1 - \theta_j(1 - s_{ij})] \sum_{k \geq 1} [\theta_j(1 - s_{ij})]^{k-1} Q_j(k\, I_{ij}). \tag{9a}$$

This sum always converges to a well-defined and finite quantity $R_{ij} \leq I_{ij}/[1 - \theta_j(1 - s_{ij})]$ for any removal distribution, even if $t_{ij} = \mathsf{E}[\tau]$ is infinite.

For $\theta_j = 0$ only the first term ($k = 1$) contributes to the sum in (9a). In that case $R_{ij} = Q_j(I_{ij}) = I_{ij} p_{ij}$ where $p_{ij} \equiv \int_0^{I_{ij}} \bar{F}_j(I_{ij} - t)\, dt / I_{ij}$ is the average probability a carcass is unremoved until the next search, and (8) reduces to Pollock's estimator $\hat{M}_{ij}^{\mathrm{P}} = C_{ij}/\hat{p}_{ij}\hat{s}_{ij}$ for any underlying removal distribution.

For $\theta_j > 0$, the kth term in the sum of (9a) accounts for carcasses that went undiscovered through $(k-1)$ searches and unremoved for about $k \times I_{ij}$ days. It's not surprising that only a few terms are necessary (usually just two or three) to evaluate R_{ij} with sufficient accuracy. Bounds are presented in Section (3) for finite approximations including simple truncation,

$$R_{ij} \approx R_{ij}^n \equiv [1 - \theta_j(1 - s_{ij})] \sum_{k=1}^{n} [\theta_j(1 - s_{ij})]^{k-1} Q_j(k\, I_{ij}). \tag{9b}$$

2.3 Parametric Examples

In this section we consider several parametric distributions commonly used for survival or lifetime analysis. To facilitate introducing a regression setting later to reflect dependence on covariates such as vegetation height, in each case we parametrize the distribution with a *rate* parameter $r_{ij} > 0$ and perhaps one or more shape parameters.

2.3.1 Exponential Persistence

For the exponential distribution, the survival function, mean, and ISF are

$$\bar{F}_j(t) \equiv \mathsf{P}[\tau > t] = e^{-r_{ij}\,t} \tag{10a}$$

$$t_{ij} \equiv \mathsf{E}[\tau] \quad = \int_0^\infty e^{-r_{ij}\,x}\,dx = 1/r_{ij} \tag{10b}$$

$$Q_j(t) \equiv \mathsf{E}[\tau \wedge t] \;= \int_0^t e^{-r_{ij}\,x}\,dx \;\; = t_{ij}[1 - e^{-t/t_{ij}}] \tag{10c}$$

for $t \geq 0$ so (7) and (9a) are geometric series with sums

$$g_j(t) = m_{ij} t_{ij} \left\{ 1 - \frac{1 - q_j}{1 - q_j\, e^{-I_{ij}/t_{ij}}} e^{-t/t_{ij}} \right\} \tag{10d}$$

$$R_{ij} = t_{ij} \frac{e^{I_{ij}/t_{ij}} - 1}{e^{I_{ij}/t_{ij}} - q_j} \tag{10e}$$

with $q_j \equiv \theta_j(1 - s_{ij})$. This leads to the exponential removal Partially Periodic estimator

$$\hat{M}^\star_{ij} \equiv \frac{C_{ij}\;I_{ij}}{\hat{R}_{ij}\;\hat{s}_{ij}} = \frac{C_{ij}\;I_{ij}}{\hat{s}_{ij}\;\hat{t}_{ij}} \left\{ \frac{e^{I_{ij}/\hat{t}_{ij}} - \theta_j(1 - s_{ij})}{e^{I_{ij}/\hat{t}_{ij}} - 1} \right\}$$

identical to (1). It reduces further to $\hat{M}^{\text{P:E}}_{ij}$ of Eqn (3b) or $\hat{M}^{\text{H}}_{ij}$ of Eqn (4) for $\theta_j = 0$ and to $\hat{M}^{\text{S}}_{ij}$ of Eqn (2) for $\theta_j = 1$.

2.3.2 Weibull Persistence

The survival function, mean, and ISF for the Weibull distribution with shape $\alpha > 0$ are

$$\bar{F}_j(t) \equiv \mathsf{P}[\tau > t] = e^{-(r_{ij}\,t)^\alpha} \tag{11a}$$

$$t_{ij} \equiv \mathsf{E}[\tau] \quad = \int_0^\infty e^{-(r_{ij}\,x)^\alpha}\,dx = \Gamma(1 + \tfrac{1}{\alpha})/r_{ij}, \tag{11b}$$

$$Q_j(t) \equiv \mathsf{E}[\tau \wedge t] \;= \int_0^t e^{-(r_{ij}\,x)^\alpha}\,dx \;\; = P\big(\tfrac{1}{\alpha}, (r_{ij}t)^\alpha\big)\, t_{ij} \tag{11c}$$

where $\Gamma(a)$ and $P(a, x)$ denote the gamma and incomplete gamma functions, respectively (Abramowitz and Stegun, 1964, §6.5), so $\hat{M}^\star_{ij} \equiv C_{ij} I_{ij}/\hat{R}_{ij}\hat{s}_{ij}$ with

$$g_j(t) = t_{ij}(1 - q_j)\, m_{ij} \sum_{k \geq 0} q_j^k P\big(\tfrac{1}{\alpha}, [r_{ij}(t + kI_{ij})]^\alpha\big) \tag{11d}$$

$$R_{ij} \equiv t_{ij}\,(1 - q_j) \sum_{k \geq 1} q_j^{k-1} P\big(\tfrac{1}{\alpha},\; (k\, r_{ij} I_{ij})^\alpha\big) \tag{11e}$$

again with $q_j \equiv \theta_j(1 - s_{ij})$ (see Section (3) for finite approximations). This is illustrated in Figure (1) and Section (2.5).

2.3.3 Log Normal Persistence

The survival function, mean, and ISF for the log normal distribution are

$$\bar{F}_j(t) \equiv \mathsf{P}[\tau > t] = \Phi\big(-\alpha \log_j(r_{ij}\, t)\big) \tag{12a}$$

$$t_{ij} \equiv \mathsf{E}[\tau] = \int_0^\infty \bar{F}_j(x)\, dx = e^{1/2\alpha^2}/r_{ij} \tag{12b}$$

$$Q_j(t) \equiv \mathsf{E}[\tau \wedge t] = \int_0^t \bar{F}_j(x)\, dx = \Phi\big(-\alpha \log_j(r_{ij}\, t)\big)\, t + \Phi\big(\alpha \log_j(r_{ij}\, t) - \tfrac{1}{\alpha}\big)\, t_{ij} \tag{12c}$$

where $\Phi(z)$ is the standard Normal CDF, and so $\hat{M}^\star_{ij} \equiv C_{ij} I_{ij}/\hat{R}_{ij}\hat{s}_{ij}$ with

$$g_j(t) = (1 - q_j)\, m_{ij} \sum_{k \ge 0} q_j^k Q_j(t + kI_{ij}) \tag{12d}$$

$$R_{ij} \equiv (1 - q_j) \sum_{k \ge 1} q_j^{k-1} Q_j(k\, I_{ij}). \tag{12e}$$

The log normal distribution is more commonly parametrized by the mean $\mu = -\log r_{ij}$ and variance $\sigma^2 = 1/\alpha^2$ of $\log \tau$.

2.3.4 Log Logistic Persistence

The survival function, mean, and ISF for the log logistic (or "Fisk") distribution are

$$\bar{F}_j(t) \equiv \mathsf{P}[\tau > t] = [1 + (r_{ij} t)^\alpha]^{-1} \tag{13a}$$

$$t_{ij} \equiv \mathsf{E}[\tau] = \int_0^\infty \frac{dx}{1 + (r_{ij} x)^\alpha} = \begin{cases} \frac{\pi/\alpha}{r_{ij} \sin(\pi/\alpha)} & \alpha > 1 \\ \infty & \alpha \le 1 \end{cases} \tag{13b}$$

$$\begin{aligned} Q_j(t) \equiv \mathsf{E}[\tau \wedge t] = \int_0^t \frac{dx}{1 + (r_{ij} x)^\alpha} &= t\; {}_2F_1\big(1, \tfrac{1}{\alpha}; 1 + \tfrac{1}{\alpha}; -(r_{ij} t)^\alpha\big) \\ &= \frac{t}{1 + (r_{ij} t)^\alpha}\; {}_2F_1\big(1, 1; 1 + \tfrac{1}{\alpha}; \frac{1}{1 + (r_{ij} t)^{-\alpha}}\big) \end{aligned} \tag{13c}$$

where ${}_2F_1(a, b; c; z)$ is Gauss' hypergeometric function (Abramowitz and Stegun, 1964, §15.1). Note $t_{ij} = \infty$ is possible for this distribution. Again $\hat{M}^\star_{ij} \equiv C_{ij} I_{ij}/\hat{R}_{ij}\hat{s}_{ij}$ with

$$g_j(t) = (1 - q_j)\, m_{ij} \sum_{k \ge 0} q_j^k Q_j(t + kI_{ij}) \tag{13d}$$

$$R_{ij} \equiv (1 - q_j) \sum_{k \ge 1} q_j^{k-1} Q_j(k\, I_{ij}) \tag{13e}$$

with finite approximations given in Eqn (19). The log logistic distribution is more commonly parametrized by the median $m = -\log r_{ij}$ and scale $s = 1/\alpha$ of $\log \tau$.

2.4 Estimating Parameters and Persistence

The parameters governing removal distributions are usually estimated with the help of *removal trials* in which some number C_0 of carcasses are placed at known locations at time $t_0 = 0$, then checked on each of some number n of succeeding days $0 < t_1 < t_2 < \cdots < t_n$ revealing counts $C_0 \geq C_1 \geq C_2 \geq \cdots \geq C_n$ of remaining carcasses (see, for example, Erickson *et al.*, 2008, §2.6). To simplify some formulas below, set $t_{n+1} \equiv \infty$ and $C_{n+1} \equiv 0$, with $\bar{F}_j(\infty) = 0$.

2.4.1 Estimating Parameters

If we were able to observe the exact lengths of time $\{\tau_k\}$ until each carcass's removal, the log likelihood function for the rate parameter r_{ij} and shape parameter α of any of the distributions considered in Sections 2.3.2–2.3.4 would be

$$\ell(\alpha, r_{ij}) = \sum_k \log f_j(\tau_k; \alpha, r_{ij})$$

where $f_j(t; \alpha, r_{ij}) \equiv -(\partial/\partial t)\bar{F}_j(t; \alpha, r_{ij})$ denotes the probability density function (pdf) for removal, with the parameter dependence made explicit. Our data are censored, however, to only the counts C_m of $\{\tau_k\}$ in the intervals (t_m, ∞) for $0 \leq m \leq n$, leading to the multinomial log likelihood

$$\ell(\alpha, r_{ij}) = \sum_{m=0}^{n} [C_m - C_{m+1}] \log\left(\bar{F}_j(t_m; \alpha, r_{ij}) - \bar{F}_j(t_{m+1}; \alpha, r_{ij})\right) \tag{14}$$

from which estimates $\hat{\alpha}$, $\hat{r}_{ij}$ can be found numerically. For equally-spaced search intervals $t_m = m\Delta$ and exponentially-distributed removal, a closed-form expression for the rate maximum likelihood estimators (MLEs) of r_{ij} and of the mean persistence time $t_{ij} = 1/r_{ij}$ are available:

$$\hat{r}_{ij} = \frac{1}{\Delta} \log\left\{1 + \frac{C_0 - C_n}{\sum_{1\leq m\leq n} C_m}\right\} = \frac{1}{\Delta} \log\left\{\frac{\sum_{0\leq m<n} C_m}{\sum_{0<m\leq n} C_m}\right\}, \qquad \hat{t}_{ij} = 1/\hat{r}_{ij} \tag{15}$$

Note this is quite different from the formula for estimating mean persistence suggested in (Erickson *et al.*, 2008, §3.3), which will systematically underestimate $\hat{t}_{ij}$. Searcher proficiency s_{ij} can also be estimated empirically from removal trial experimental data (see Section (2.4.3)).

2.4.2 Empirical Persistence

An alternative to the parametric models presented in Section (2.3) is to estimate R_{ij} directly from experimental data gathered in a removal trial. If θ_j and s_{ij} (and hence q_j) are known, then the maximum likelihood estimator (MLE) $\hat{R}_{ij}$ can be computed from the MLE $\hat{Q}_j(t)$ of the ISF $Q_j(t)$.

Unfortunately the MLE for the ISF is not uniquely determined— the likelihood takes the same maximum value at all non-decreasing functions $Q(t)$ satisfying $\hat{Q}_j^-(t) \le Q(t) \le \hat{Q}_j^+(t)$, with lower and upper limits given by:

$$\hat{Q}_j^-(t) = \sum_{k=1}^{n} \frac{C_{k-1} - C_k}{C_0}(t_{k-1} \wedge t) + \frac{C_n}{C_0} t_n \qquad \hat{Q}_j^+(t) = \sum_{k=1}^{n} \frac{C_{k-1} - C_k}{C_0}(t_k \wedge t) + \frac{C_n}{C_0} t \tag{16}$$

These lead in turn to lower and upper MLEs for R_{ij} of

$$\hat{R}_{ij}^{\pm} \equiv (1 - q_j) \sum_{k \ge 1} q_j^{k-1} \hat{Q}_j^{\pm}(k\, I_{ij})$$

and hence to Partially Periodic estimators

$$\hat{M}_{ij}^{\star\pm} \equiv \frac{C_{ij}\ I_{ij}}{\hat{R}_{ij}^{\mp}\ \hat{s}_{ij}}. \tag{17}$$

The estimator $\hat{M}_{ij}^{\star+}$ generated from the lower MLE $\hat{R}_{ij}^-$ is conservative, in that it will slightly overestimate M_{ij} on average, while on average that $\hat{M}_{ij}^{\star-}$ generated from $\hat{R}_{ij}^+$ will slightly underestimate M_{ij}. Note too that the sums for evaluating both R_{ij}^- and R_{ij}^+ entail at most $\lceil t_n / I_{ij} \rceil$ terms, since for $t > t_n$ the function $\hat{Q}_j^-(t)$ is constant and $\hat{Q}_j^+(t)$ is linear, leading to summable geometric series. The difference $[\hat{Q}_j^+(t) - \hat{Q}_j^-(t)]$ for $t \le t_n$ are weighted averages of the inter-search intervals $[t_k - t_{k-1}]$, hence smaller than the largest such interval.

2.4.3 Regression

Now suppose that in a trial we have a vector of $p \ge 1$ covariates for each carcass that might affect the rate of removal, such as vegetation height or slope. Model the rate parameter r_{ij} for the kth carcass as

$$r_{ij} = \exp(X_k \cdot \beta)$$

for a p-dimensional vector β of regression coefficients, and denote by t_k^- the last search time $\{t_m\}$ the carcass was still present, and by t_k^+ the first search time the carcass was absent (or ∞ if the trial ended before it was removed). The log likelihood function of (14) becomes

$$\ell(\alpha, \beta) = \sum_k \log \left[\bar{F}_j\big(t_k^-; \alpha, \exp(X_k \cdot \beta)\big) - \bar{F}_j\big(t_k^+; \alpha, \exp(X_k \cdot \beta)\big) \right] \tag{18}$$

which can be maximized numerically in the parameters α and β.

These covariates may also affect the probability of discovery s_{ij}, which could also be modeled in log-linear fashion as

$$s_{ij} = \exp(X_k \cdot \gamma)$$

for an uncertain p-dimensional vector γ of regression coefficients.

2.5 Illustration

Figure 1 shows a simulation of four $I_{ij} = 10\,\mathrm{d}$ periods with average daily mortality rate of $m_{ij} = 3\,\mathrm{d}^{-1}$. Persistence distributions are Weibull with shape $\alpha = 0.70$ and mean $t_{ij} = 15\,\mathrm{d}$; search proficiency is $s_{ij} = 30\%$, and $\theta_j = 50\%$ of carcasses remain discoverable in subsequent periods (a compromise between the Shoenfeld and Pollock values). Counts of discoverable carcasses are shown as stair-step curve beginning and ending at open and filled squares, that increases (resp. decreases) by one with each new fatality (resp. removal by scavengers), and decreases by the number C_{ij} of carcasses discovered and removed by searchers (shown as a red downward arrow) and by an additional number that become undiscoverable. Expected numbers of discoverable carcasses are shown as smooth curves beginning and ending at open and filled circles. For these values, Erickson & Johnson's estimator has a bias of -50% (*i.e.*, on average $\hat{M}_{ij}^{\mathrm{EJ}} \approx \frac{1}{2} M_{ij}$) and Shoenfeld's $\hat{M}_{ij}^{\mathrm{S}}$ has bias -34.2%, because each assumes that *all* carcasses remain discoverable while in fact only half do. Pollock's estimator $\hat{M}_{ij}^{\mathrm{P:W}}$ has positive bias $+22.8\%$, because it assumes that *no* carcasses remain discoverable while in fact half do. Pollock's $\hat{M}_{ij}^{\mathrm{P:E}}$ (and Huso's identical $\hat{M}_{ij}^{\mathrm{H}}$) comes closer, with just $+2.7\%$ bias, because the reduction from its incorrect assumption of exponential removal distributions and the inflation from its incorrect assumption that intervals begin without discoverable carcasses nearly cancel out (a coincidence arising from our choice of parameter values). The new Partially Periodic estimator $\hat{M}_{ij}^{\star}$ has zero bias.

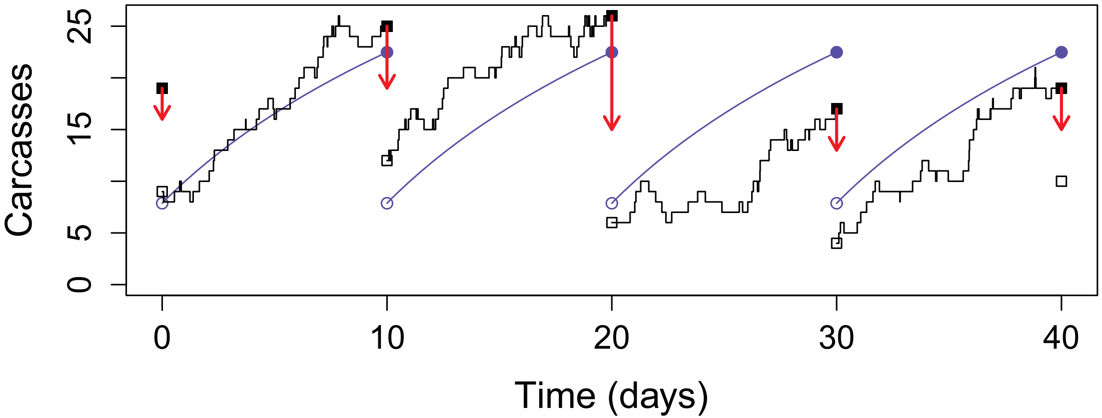

Figure 1: One draw (stair-step) from random distribution of all carcasses present at times t, for $0 \le t \le 40\,\mathrm{d}$. Expected value $g(t)$ is shown as solid line, beginning and ending search periods at open and filled circles, removal by search teams as downward arrows.

For exponential removal times ($\alpha = 1$), the new estimator will always lie between the estimators

$$\hat{M}_{ij}^{\mathrm{S}} < \hat{M}_{ij}^{\star} < \hat{M}_{ij}^{\mathrm{P}}$$

of Shoenfeld and Pollock (or, equivalently, Huso), with negligible differences among them whenever $I_{ij}/\hat{t}_{ij}$ is large. The differences are larger with more frequent searches, but never exceed a factor of s_{ij}: for any I_{ij} and $\hat{t}_{ij}$, always $s_{ij}\hat{M}_{ij}^{\mathrm{P}} \le \hat{M}_{ij}^{\mathrm{S}} \le \hat{M}_{ij}^{\mathrm{P}} \le \hat{M}_{ij}^{\mathrm{S}}/s_{ij}$.

3 Computation

3.1 Evaluating R_{ij}

Since $Q_j(t) \le t$ and $Q_j(t) \le \hat{t}_{ij}$, the truncation error incurred by approximating R_{ij} with just the first n terms as in Eqn (9b)

$$R_{ij}^n \equiv (1-q_j)\sum_{k=1}^{n} q_j^{k-1} Q_j(k\, I_{ij})$$

is bounded above by both of

$$\begin{aligned} R_{ij} - R_{ij}^n &\le (1-q_j)\sum_{k>n} q_j^{k-1} k\, I_{ij} &&= q_j^n\, I_{ij}\,[n + 1/(1-q_j)] \\ R_{ij} - R_{ij}^n &\le (1-q_j)\sum_{k>n} q_j^{k-1}\, \hat{t}_{ij} &&= q_j^n\, \hat{t}_{ij} \end{aligned}$$

and, by monotonicity, is bounded below by

$$R_{ij} - R_{ij}^n \ge (1-q_j)\sum_{k>n} q_j^{k-1}\, Q_j\big(n\, I_{ij}\big) = q_j^n\, Q_j(n\, I_{ij}),$$

leading to the two-sided bound

$$R_{ij}^{n-} \equiv R_{ij}^n + q_j^n\, Q_j(n\, I_{ij}) \quad\le\quad R_{ij} \quad\le\quad R_{ij}^{n+} \equiv R_{ij}^n + q_j^n \min\Big(\hat{t}_{ij},\ I_{ij}\big[n + 1/(1-q_j)\big]\Big). \quad (19)$$

For the parameter values used in the simulation of Section (2.5) presented in Figure 1 the error is bounded by $(0.5 * (1-0.3)e^{-2.5})^N = (0.0288)^N$, so just $N = 2$ terms suffice for 99.92% accuracy.

3.2 Special Functions

The partially-periodic estimator $\hat{M}_{ij}^{\star}$ of Eqn (1) is simple to evaluate in closed form under the assumption that removal times have exponential distributions, as is the estimator $\hat{M}_{ij}^{\star+}$ of Eqn (17) based on non-parametric empirical estimation of removal distributions. The version of $\hat{M}_{ij}^{\star}$ for log normal removal distributions presented in Section (2.3.3) requires only the cumulative normal distribution function $\Phi(z)$, available in virtually every computing environment, but the estimators for assumed log logistic or Weibull removal distributions require slightly less commonly used functions.

The complete and incomplete gamma functions $\Gamma(a)$ and $P(a,x)$ required for the Weibull estimator of Section (2.3.2) are included in `R` (R Core Team, 2012) as `gamma(a)` and `pgamma(x,a)`, respectively, and are also included in Matlab, Mathematica, the gnu scientific library (gsl: Galassi *et al.*, 2009), and other standard computational environments. In Microsoft Excel they are available as $\Gamma(a) =$ `EXP(GAMMALN.PRECISE(a))` and $P(a,x) =$ `GAMMA.DIST(x,a,1,TRUE)`, respectively (for versions of MS Excel prior to 10, use `GAMMALN` and `GAMMADIST` instead).

Gauss' hypergeometric function ${}_2F_1(a,b;c;z)$ needed for the log logistic removal models of Section 2.3.4) is available in MATLAB, in Mathematica, and `R` (using the `gsl` package). While it's not included in MS Excel, certain special cases are— for example, for $\alpha = 2$, $Q_j(t) = \arctan(r_{ij}t)/r_{ij}$ and (13e) becomes

$$\begin{aligned} R_{ij} &= (1-q_j)\sum_{k\ge 1} q_j^{k-1}\arctan(kr_{ij}I_{ij})/r_{ij} \\ \approx R_{ij}^{n-} &\equiv (1-q_j)\sum_{k=1}^{n} q_j^{k-1}\arctan(kr_{ij}I_{ij})/r_{ij} + q_j^n\arctan(nr_{ij}I_{ij})/r_{ij} \end{aligned}$$

for any small n, easily evaluated in Excel, with an error bounded by Eqn (19).

4 Non-constant Removal Rates and Proficiencies

One part of a 2011 study by the California Wind Energy Association (Warren-Hicks *et al.*, 2012) consisted of a removal trial in which a number of bird and bat carcasses were placed in known locations and followed for 45 days. At intervals, searches would be undertaken and each discovered carcass would be recorded. Periodically the trial coordinators would check each carcass to see if it had yet been removed by scavengers.

4.1 Estimating Proficiency Time Dependence

A key finding of this study is that the proficiency s_{ij} does *not* appear to be constant, unrelated to the age of the carcass— rather, that older carcasses have a lower probability of discovery than fresher carcasses. This is illustrated in Figure (2), which shows the data for small birds: 38 successful discoveries of carcasses aged 1–28 days, shown as small circles ∘ at height $y = 1$, and 185 undiscovered carcasses, aged 1–45 days, shown as small circles at height $y = 0$ (a small jitter is added to the locations of each circle to reveal multiplicity). The overall average proficiency is $\bar{s}_{ij} = 17\%$, but there is clear evidence that $\bar{s}_{ij}(t)$ diminishes with carcass age t. The figure also shows an empirical exponential moving-average estimate (with a 5-day window) as a dashed red line, and the best fit with a logistic regression model shown as a solid blue curve:

$$\hat{s}_{ij}(t) = \left(1 + e^{0.6441+0.0911t}\right)^{-1}, \tag{20a}$$

starting at $\hat{s}_{ij}(0) = 45.75\%$, falling to the overall average $\hat{s}_{ij}(10.3) = 17\%$ after about 10 days and continuing to fall down to a negligible $\hat{s}_{ij}(45) = 0.86\%$. The two curves are in substantial agreement throughout the range, suggesting that the logistic regression model is a good fit. The best fit for a model with simple exponentially-decreasing proficiency

$$\hat{s}_{ij}(t) = e^{-1.017-0.0777t} \tag{20b}$$

(in green) is virtually indistinguishable; we'll return to this one in Section (4.3).

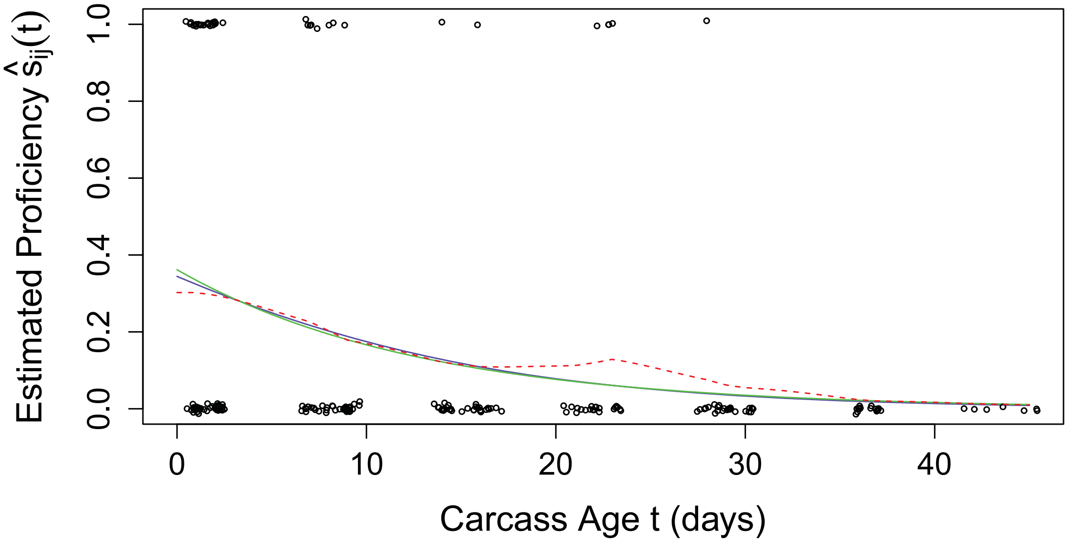

Figure 2: Time-dependence of search proficiency $\hat{s}_{ij}(t)$. Dashed red curve is nonparametric moving-average estimator (exponential window, width 5 days), solid blue and green curves are best logistic-regression and exponential fits (see Eqn (20)).

4.2 Estimating Removal Time Dependence

Other investigators (such as Bispo *et al.*, 2012) have reported earlier that exponential distributions offer a worse fit to empirical data on carcass removal by scavengers than several alternatives, and data from Warren-Hicks *et al.* (2012) reaffirm this finding. Figure (3) shows the upper and lower empirical survival curves (Kaplan and Meier, 1958) for these censored data, along with best fits for Exponential Distribution (dashed red curve) and Weibull (solid blue curve). Evidently the Weibull fits far better. Both log-logistic and log-normal fits are similar to Weibull, and far better than exponential, suggesting that hazard rate (daily probability of removal by scavengers), like search proficiency, diminishes over time. The best-fit Weibull had shape parameter $\hat{\alpha} = 0.4606$ with a Standard Error of $0.0532\,\mathrm{d}$, about 10.31 Standard Errors below the value $\alpha = 1$ corresponding to the exponential distribution, leading to emphatic rejection of exponentially-distributed removal. The estimated rate parameter is $\hat{r}_{ij} = 0.07944$, for a mean persistence time of

$$\hat{t}_{ij} = \Gamma(1 + 1/\hat{\alpha})/\hat{r}_{ij} = 29.64\,\mathrm{d},$$

substantially longer than the estimate $\hat{t}_{ij} = 16.68\,\mathrm{d}$ under the exponential model which (see Figure (3)) systematically underestimates early removal and overestimates late removal.

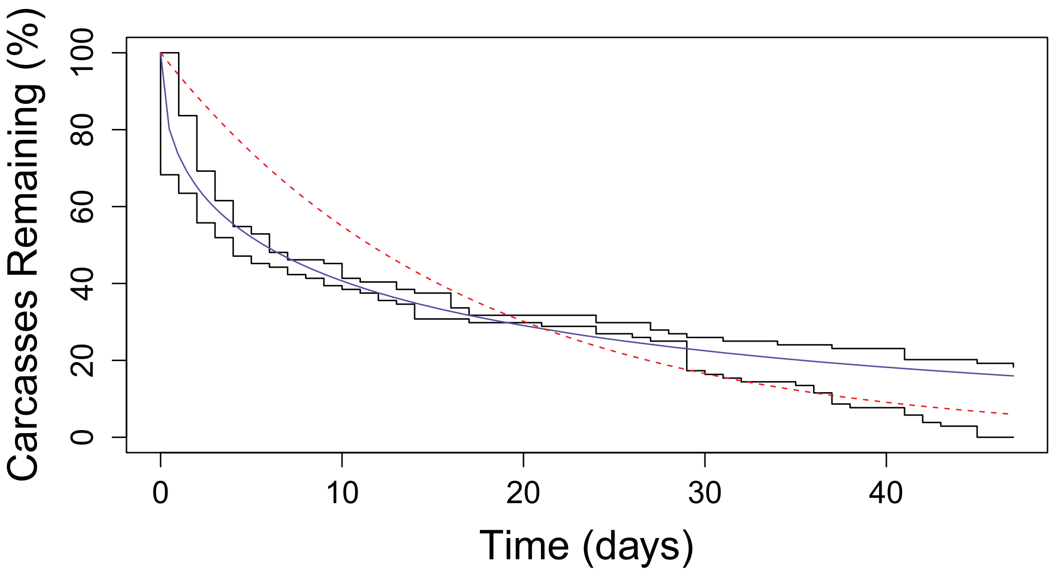

Figure 3: Upper and lower empirical (Kaplan-Meier) Removal curves (solid black stair-steps), with best Weibull fit (solid blue curve) and best Exponential fit (dashed red curve).

4.3 Adapting the Model and Mortality Estimators

Although the model and mortality estimator of Section (2.2) makes no assumptions on removal distributions, and the parametric examples presented in Section (2.3) include the Weibull, Lognormal, and Log Logistic, all of which fit our data well, each of of these (along with all other published mortality estimators we are aware of) are built on the assumption that search proficiency is constant, unrelated to carcass age; in Section (4.1) we showed that this assumption appears to be false. In this section we will adapt the model and estimators of Sections (2.2) and (2.3) to accommodate age-dependent proficiency.

By the same argument and changes-of-variables that led to Eqn (9a), the number of carcasses counted at each search will have a Poisson distribution with mean

$$c_{ij} = m_{ij} \sum_{k=0}^{\infty} \theta^k \int_{kI_{ij}}^{(k+1)I_{ij}} \bar{F}_j(x) s_{ij}(x) \prod_{1 \le n \le k} \left[1 - s_{ij}(x - nI_{ij})\right] dx \tag{21a}$$

or, for $\theta = 0$ as assumed by Pollock and Huso, just one term $k = 0$:

$$= m_{ij} \int_0^{I_{ij}} \bar{F}_j(x) s_{ij}(x)\, dx. \tag{21b}$$

Using $\mathsf{E}[M_{ij}] = I_{ij} m_{ij}$, this leads to a variation on (8),

$$\hat{M}^{\star}_{ij} = \frac{C_{ij}\ I_{ij}}{R^{\star}_{ij}} \tag{22a}$$

where now $R^\star_{ij}$ is given by

$$R^\star_{ij} \equiv \sum_{k=0}^{\infty} \theta^k \int_{kI_{ij}}^{(k+1)I_{ij}} \bar{F}_j(x) s_{ij}(x) \prod_{1 \le n \le k} \big[1 - s_{ij}(x - nI_{ij})\big]\, dx. \tag{22b}$$

This can be computed numerically for any specified proficiency function $s_{ij}(x)$ (like the logistic or exponential regressions of Eqn (20a) or Eqn (20b)) and any of the empirical or parametric removal distributions of Section (2.3) or Section (2.4.2).

4.3.1 An Efficient Computational Scheme

For exponentially diminishing proficiency $s_{ij}(t) = \exp(-a - bt)$ (which fits our data well, as shown in Figure (2)), $R^\star_{ij}$ is the sum

$$R^\star_{ij} = I_{ij} \sum_{k=0}^{\infty} T_k$$

of terms

$$\begin{aligned} T_k &= \theta^k I_{ij}^{-1} \int_{kI_{ij}}^{(k+1)I_{ij}} \bar{F}_j(t) e^{-a-bt} \prod_{1 \le n \le k} \big[1 - e^{-a-b(t-nI_{ij})}\big]\, dt \\ &= \theta^k \int_0^1 \bar{F}_j((k+x)I_{ij}) e^{-a-bI_{ij}(x+k)} \prod_{0 \le n < k} \big[1 - e^{-a-bI_{ij}(x+n)}\big]\, dx \end{aligned}$$

each expressible as the sum of 2^k terms of the form

$$Q^\star_{kmn} = \theta^k (-1)^{m+1} \int_0^1 \bar{F}_j\big((k+x)I_{ij}\big) e^{-m\,(a+bI_{ij}\,x) - n\,bI_{ij}}\, dx \tag{23}$$

for suitable nonnegative integers k, m, n that can be enumerated recursively. The first few terms are

$$\begin{aligned} T_0 &= Q^\star_{010} \\ T_1 &= Q^\star_{111} + Q^\star_{121} \\ T_2 &= Q^\star_{212} + Q^\star_{223} + Q^\star_{222} + Q^\star_{233} \\ T_3 &= Q^\star_{313} + Q^\star_{325} + Q^\star_{324} + Q^\star_{336} + Q^\star_{323} + Q^\star_{335} + Q^\star_{334} + Q^\star_{346} \end{aligned}$$

The integral in (23) is easily evaluated using Simpson's rule, or is available in closed form for Weibull removal with shape parameters $\alpha = 1$ (the exponential case) or $\alpha = \frac{1}{2}$ (very close to our estimated shape parameter $\hat{\alpha} = 0.4606$ for small birds). The truncation error from using only the first N terms $0 \le k < N$ in (22b) is bounded by

$$0 \le \text{Truncation Error} \le \frac{\theta^N \bar{F}_j(N\,I_{ij}) \exp(-a - N\,bI_{ij})}{\max\{bI_{ij}, (1 - \theta e^{-bI_{ij}})\}}$$

For the parameter estimates in our study[1], a 40% error would be made using only $N = 1$ term (*i.e.*, neglecting bleed-through), but the error falls to 8% with $N = 2$ terms and below 0.5% with $N = 4$, indicating that a significant fraction of old carcasses were present from the immediately preceding period, but essentially none from more than three periods earlier. The values of $R^\star_{ij}$ and corresponding estimators $\hat{M}^\star_{ij} = C_{ij} I_{ij}/R^\star_{ij}$ with $\theta = 50\%$ were:

I_{ij}	2 d	7 d	14 d	28 d
$R^\star_{ij}$	1.094	2.2224	2.9013	3.327
$\hat{M}^\star_{ij}$	$1.8\,C_{ij}$	$3.15\,C_{ij}$	$4.8\,C_{ij}$	$8.4\,C_{ij}$

5 Interval Estimates for M_{ij} and m_{ij}

Each of the estimators in Sections (2) and (4) is of the form "$\hat{M}_{ij} = \kappa C_{ij}$" for some $\kappa \geq 1$, proportional to the carcass count C_{ij}, because in each C_{ij} has either a binomial or a Poisson distribution with mean proportional to M_{ij} or to $m_{ij} = \mathsf{E} M_{ij}/I_{ij}$:

$$\mathsf{E}[M_{ij}] = m_{ij} I_{ij}, \qquad \mathsf{E}[C_{ij}] = m_{ij} I_{ij}/\kappa, \qquad \kappa \equiv \frac{I_{ij}}{s_{ij} R_{ij}} \text{ or } \frac{I_{ij}}{R^\star_{ij}} \tag{24a}$$

where R_{ij} is given by Eqn (9a) and $R^\star_{ij}$ by Eqn (22b). In this Section we present Confidence Interval estimators for M_{ij} and m_{ij}.

5.1 Estimating M_{ij} when $\theta = 0$

If $\theta = 0$ then all of the C_{ij} carcasses discovered will be from the M_{ij} of the current period I_{ij}, with conditional distribution

$$C_{ij} \mid M_{ij} \sim \mathsf{Bi}(M_{ij}, 1/\kappa).$$

If the constant κ is known precisely (if θ_j, I_{ij}, s_{ij}, and the removal distribution including its parameters are all known, for example), then an exact Confidence Interval for $M_{ij} \approx \hat{M}^\star_{ij} = \kappa C_{ij}$ can be constructed as follows. For any chosen confidence level γ (like 0.90, for example), an exact $100\gamma\%$ Confidence Interval is given by

$$\gamma \leq \mathsf{P}\big\{\texttt{lo}(C_{ij}) \leq M_{ij} \leq \texttt{hi}(C_{ij})\big\} \tag{24b}$$

where the functions `lo()` and `hi()` are given for integers $c \geq 0$ by

$$\texttt{lo}(c) = \sup\left\{m \geq c : \texttt{pbeta(1/kap; c+1, m-c)} \leq \frac{1-\gamma}{2}\right\}$$
$$\texttt{hi}(c) = \inf\left\{m \geq c : \texttt{pbeta(1/kap; c, m+1-c)} \geq \frac{1+\gamma}{2}\right\}$$

---

[1] Maximum likelihood estimates were $\hat{\alpha} \approx 0.4606$, $\hat{r}_{ij} \approx 0.07944$, $\hat{a} = 1.017$ and $\hat{b} = 0.0777$

For large C_{ij} and moderate κ these are approximately

$$\texttt{lo}(c), \texttt{hi}(c) \approx \kappa \left[c \pm \sqrt{c}\; z\sqrt{(\kappa-1)/\kappa}\right]$$

for $z := \Phi^{-1}\left(\frac{1+\gamma}{2}\right)$, so the CI widths are roughly proportional to $\sqrt{c}$ for large c. They fall to zero for $c = 0$.

5.2 Estimating $\mathsf{E}M_{ij}$ when $0 \le \theta \le 1$

If $\theta > 0$ some carcasses discovered in a search may have arisen from fatalities in earlier time period— so it is possible to have a positive count $C_{ij} > 0$ even if $M_{ij} = 0$, making it challenging to find interval estimates for M_{ij} based only on the count C_{ij} from the current period. Under the assumption of near periodicity, however, even though the actual fatality counts M_{ij} will vary from period to period by chance, the *mean* fatality counts $\mathsf{E}M_{ij} = m_{ij}I_{ij}$ should be approximately constant. An exact $100\gamma\%$ Confidence Interval is given by

$$\gamma \le \mathsf{P}\left\{\texttt{lo}(C_{ij}) \le \mathsf{E}M_{ij} \le \texttt{hi}(C_{ij})\right\} \tag{24c}$$

where the functions `lo()` and `hi()` are gamma distribution quantiles determined for integers $c \ge 0$ by the relations

$$(1-\gamma)/2 = P(c,\ \texttt{lo}(c)/\kappa) \qquad\qquad (1+\gamma)/2 = P(c+1,\ \texttt{hi}(c)/\kappa). \tag{24d}$$

In `R`, the solutions (with variables `c`, `gam` and `kap` for c, γ and κ respectively) are

$$\texttt{lo}(c) = \texttt{kap * qgamma((1-gam)/2, c);}$$
$$\texttt{hi}(c) = \texttt{kap * qgamma((1+gam)/2, c+1);}$$

with similar formulas in MS Excel (where `GAMMA.INV(q,a,1)` takes the place of `R`'s `qgamma(q, a)`) or other environments. For example, with the parameter values used in the simulation shown in Figure 1, $R_{ij} = 0.49956$, $I_{ij}/t_{ij} = 10/15 = 0.6667$ and $s_{ij} = 0.3$, so $\kappa = I_{ij}/(R_{ij}s_{ij}) \approx 4.4483$. The proposed estimator is $\hat{M}^{\star}_{ij} = \kappa C_{ij} \approx 4.45 \times C_{ij}$, and $\gamma = 90\%$ confidence interval estimates of M_{ij} (whose true value averaged $m_{ij}I_{ij} = 30$ in the simulation) for various count values of C_{ij} would be:

C_{ij}	lo	$\hat{M}^{\star}_{ij}$	hi
0	0.00	0.00	13.33
1	0.23	4.45	21.10
2	1.58	8.90	28.01
3	3.64	13.35	34.49
4	6.08	17.79	40.72
5	8.76	22.24	46.77
6	11.62	26.69	52.68
7	14.61	31.14	58.49
8	17.71	35.59	64.21
9	20.89	40.04	69.86
10	24.13	44.48	75.45
11	27.44	48.93	80.99
12	30.80	53.38	86.49
13	34.21	57.83	91.94
14	37.65	62.28	97.36
15	41.13	66.73	102.74

This illustrates how imprecisely M_{ij} is determined by the counts C_{ij} (especially for low counts) even if α, θ_j, I_{ij}, s_{ij}, and t_{ij} are all known precisely. If any of these must be estimated, then the uncertainty about M_{ij} is greater.

Bayesian estimates and Credible Intervals are also available for conjugate gamma prior distribution $M_{ij} \sim \mathsf{Ga}(a, b)$,

$$\mathsf{E}[M_{ij} \mid C_{ij}] = \frac{\kappa}{1+\kappa b}\,[C_{ij} + a] = \frac{\hat{M}^{\star}_{ij} + \kappa a}{1+\kappa b} \tag{25a}$$

$$\gamma = \mathsf{P}\Big\{\texttt{lo}(C_{ij}) \le M_{ij} \le \texttt{hi}(C_{ij})\Big\} \tag{25b}$$

$$\texttt{lo}(c) = \texttt{qgamma((1-gam)/2, c+a) * kap/(1+kap*b);} \tag{25c}$$

$$\texttt{hi}(c) = \texttt{qgamma((1+gam)/2, c+a) * kap/(1+kap*b);} \tag{25d}$$

The reference or "noninformative" choice would be $a = \frac{1}{2}$, $b = 0$; more generally, experience in similar settings may suggest an appropriate "prior sample size" b and "prior sample sum" a. Note the same Confidence Intervals and Credible Intervals also apply to any of the estimators $\hat{M}^{\text{EJ}}_{ij}$, $\hat{M}^{\text{H}}_{ij}$, $\hat{M}^{\text{S}}_{ij}$, $\hat{M}^{\text{H}}_{ij}$, since they are special cases of $\hat{M}^{\star}_{ij}$.

A Appendix: Notation Glossary

For convenience we collect here notation used in this document:

$\mathfrak{g}_0$ be the number of discoverable carcasses on the ground at the start of a period,
$\mathfrak{g}_1$ be the number of discoverable carcasses on the ground at the end of a period.

By periodicity we take to be the same for all periods, though they may vary with the turbine i (but to simplify the notation we ignore this). At turbine i and time period j, let:

C_{ij} (count) = number of carcasses counted,
I_{ij} (search interval) = number of days between searches,
M_{ij} (mortality) = true number of carcasses during interval,
m_{ij} (mortality rate) = daily average arrival rate of carcasses,
p_{ij} (persistence probability) = probability of remaining unremoved until next search,
r_{ij} (rate parameter) = common parameter for all removal distributions,
s_{ij} (search proficiency) = probability a carcass will be discovered,
t_{ij} (mean persistence) = average number of days a carcass remains unremoved,
α (shape parameter) = common parameter for all removal distributions,
θ_j (periodicity) = fraction of undiscovered carcasses that remain discoverable,
τ (persistence time) = number of days a carcass remains unremoved,
q_j $(\theta_j(1 - s_{ij}))$ = probability undiscovered but still discoverable,
$\bar{F}_j(t)$ (survival function) $= \mathsf{P}[\tau > t]$,
$Q_j(t)$ (ISF) $= \mathsf{E}[\tau \wedge t] = \int_0^t \bar{F}_j(x)\,dx$,

APPENDIX B:
A New Survey Method for Detection Probability Trials for Partial Periodic Estimator

Introduction

This study identified and explained major influences on detection probability for periodic searches of bird and bat fatalities. These discoveries led to the creation of a new Partial Periodic Estimator (Appendix A), which requires modifications to the traditional survey methodology. The following lays out the framework for wind energy fatality monitoring surveys and detection probability trials that support the new estimator and account for the major influences on detection probability.

1. Time dependent carcass persistence and searcher proficiency: It has been well documented that carcass persistence is dependent on carcass age, and this study shows that search proficiency is also dependent on carcass age.
2. Carcasses can persist through multiple search intervals, allowing for multiple detection events: Some of the previous fatality estimation equations (*e.g.,* Pollock and Huso) do not account for the common occurrence of carcasses being deposited in one search interval that persist into subsequent intervals and are detected at a later date. The Partial Periodic Estimator measures this “bleed-through” process with a new term, “theta,” which is the proportion of undiscovered carcasses that remain discoverable.
3. Other covariates such as vegetation height can also have strong influences on detection probability.

Preliminary Scavenger Removal Trial

Before a main study begins, a preliminary traditional 60-day scavenger removal trial is required to estimate the ballpark mean persistence of carcasses (bats, small birds, and large birds) and variation in removal times. The recommended main study search interval is equal to the shortest mean persistence of the three carcass types placed. The recommended main detection probability trial length is three times the mean persistence of the longest persisting carcass type. The number of carcasses used in the main detection probability trial for each size category should be based on the variation of removal times.

Main Study Detection Probability Trial

Carcass Placement

Carcass placement timing should occur to simulate the assumed steady random rate of deposit. Carcasses should be placed at random positions in a search area to account for covariates such as vegetation height and slope. Carcasses should be marked to distinguish them as trial carcasses and not true fatalities. Carcasses should be mapped with sub-meter accurate Global Positioning System (GPS) receivers, or their positions should be cryptically marked to help a project field manager certify their presence while keeping field technicians blind to their presence. Main study detection probability trials should occur at least once per season, and the trial length should be equal to three times the mean persistence of the longest persisting carcass type in the preliminary scavenger removal trial. All carcasses should be placed at monitored wind turbines.

Integrated Carcass Persistence and Proficiency Detection Events

For any given carcass and search, the probability of persistence and detection (searcher proficiency) are both time dependent and dependent on one another. This makes it highly effective and desirable to measure these outcomes together in an integrated trial, rather than in two independent trials.

After placing trial carcasses strategically at monitored wind turbines, carcass persistence and searcher proficiency needs to be measured.

To establish carcass persistence, a traditional scavenger removal trial schedule of carcass checks is recommended for all trial carcasses –the project field manager checks carcasses every day for the first week, every three days for the next two weeks, and then every seven days until all carcasses are removed or the end of the trial is reached. In addition to the traditional schedule of carcass checks, supplemental carcass checks should occur for trial carcasses on search days. Note that many of the supplemental carcass checks will overlap with the traditional schedule of carcass checks and will not require extra effort. Carcass checks of trial carcasses on the day of searches should be conducted after field technicians complete their searches to maintain the searchers' blindness.

To establish searcher proficiency, field technicians record all marked carcasses they detect while conducting their standard scheduled searches. They should be instructed not to disturb these marked carcasses; they are left in place for future project field manager persistence carcass checks. Because the project field manager conducts carcass checks of trial carcasses on search days, the true persistence status of those trial carcasses is known; therefore negative searcher detections can interpreted as either a searcher's miss of a persisting trial carcass or that the trial carcass was removed by scavengers.

Integrating the carcass persistence and searcher proficiency trials can simultaneously produce time dependent carcass persistence and searcher proficiency functions for the same set of trial carcasses.

Search Interval Bleed-through of Carcasses: Theta

The final term that needs to be measured for the Partial Periodic Estimator is theta, the fraction of undiscovered carcasses that remain discoverable over time through multiple search intervals. Because trial carcasses are placed to simulate a random steady state of deposit at monitored wind turbines and the persistence and detection of trial carcasses are tracked, the number of trial carcasses that are not detected and not removed in one interval that persist to be possibly detected in a subsequent interval can be measured.

Collateral Data and Advantages to the New Method

Because a preliminary persistence trial is conducted first, proper trial carcass sample size, trial length, and search interval can be established for the main monitoring program ahead of time. This will introduce an evidence-based approach rather than guessing or using a "rule-of-thumb" to establish these aspects of the program.

The data collected from the new method can be used to source estimates for all four traditional fatality estimation equations reviewed in this study. The traditional persistence carcass check schedule is conserved, and the traditional simple initial fresh carcass searcher proficiencies can be extracted from the initial detection outcome of this method. This can allow for easy comparisons of estimator results to compare to previous studies that used other estimators. In addition, a remarkably simple empirical estimator is also sourced by the data collected and can be used as an independent check on the Partial Periodic Estimator. The number of total searcher-detected trial carcasses divided by the number of placed trial carcasses should be equal to (or close to) the overall detection probability derived by the Partial Periodic Estimator. This is because the effects of the integrated time dependent probabilities of carcasses persistence and searcher proficiency as well as the bleed-through theta mechanism are implicit in the proportional detection outcomes of this new method.

Overall, this new method and estimator are much more sensitive to the major influences that affect detection probability, reducing bias and improving the predictive power of estimating the impacts of wind turbines on wildlife.

APPENDIX C:
Data Dictionary & Data Fields Used for Recording Carcasses

Table C-1: Data Dictionary

Variable	Description	Units
ID	Unique record identifier for all data rows	Number
Date	Date that a status check or search took place	Julian date format
String	Unique identifier for a collection of turbines where trial carcasses were placed and searches occurred	Unique number
Species	The species or unknown species determination (ex UNRA, unknown raptor)	AOU species code
Photo	Unique identifier per photo	Photo number
Sex	The sex determination of trial carcasses, if known	U=unknown; M=Male; F=Female
Age	The age class of the trial carcass, if known	A=adult; J=juvenile; U=unknown
Class	The group status of trial carcass, Bird or Bat	Bird or Bat
Grid_Cell	The dominant grid cell that the carcass occupies on specified date	Alpha-numeric map key
PositionID	ID at time of search, based on last known position	Carcass_ID + position modifier
AssignedID	ID after QA and analysis, may combine several unknown or found IDs	Carcass_ID
PID	An identifying number for the project field manager who conduct the status check. Searcher that conduct the search	See data file for codes
Person	Project field manager or field technician	Name
SearchDay	Does record represent a day when searchers were present	Yes / No
DetectionStatus	The detection outcome generated by a status check or search	P = placement of carcass; F = found carcass; NF = a not found carcass; NC = a not checked carcass position (only after many prior checks, and assurance that carcass has been removed)

Variable	Description	Units
DetectionType	The type of detection (if detected)* ** If a specific carcass was ever detected during the study, it was considered a detection.*	S: Found during standard status check without additional effort; F: Found during flushing search around last known location of carcass; I: Found incidentally at unknown position without systematic search; 0: Found but not enough evidence to be considered fatality; M: Found carcass due to Marker (FM) or Did Not Find the Marker (NFM)
PositionPresence	Indictor of carcass presence at time of search	1=present; 0=absent
AssignedPresence	Indicator of carcass presence after analysis and QA	1=present; 0=absent
Veg_HT	Vegetation height	Inches
ScavengerIndex	A subjective index of the carcass "attraction" to a scavenger on a day	Index 1: Fresh carcass and very attractive for removal/scavenging; Index 2: Partially scavenged or decayed carcass , moderately attractive for removal/scavenging; Index 3: Completely scavenged or decayed (no remaining edible or attractive tissue), low attraction for removal/scavenging
GPSMarkID	Garmin record ID; allows sync with latitude and longitude	Number
Latitude	Position where carcass found during search	GPS Lat
Longitude	Position where carcass found during search	GPS Long
Note	Any field notes made by searcher or project field manager	Text
BlockNum	Block ID: contains multiple strings searched in a consistent time period	Ranges from 1 – 4
DistanceSighted	Distance from searcher to found carcass	Meters

Variable	Description	Units
TrialCarcass	Indicator of a trial carcass placed at t=0	Yes / No
TemperatureHighF	Daily high temperature	Degrees F
TemperatureAvgF	Daily average temperature	Degrees F
TemperatureLowF	Daily low temperature	Degrees F
DewpointHighF	Daily high dewpoint	Degrees F
DewpointAvgF	Daily average dewpoint	Degrees F
DewpointLowF	Daily low dewpoint	Degrees F
HumidityHigh	Daily high humidity	Percent
HumidityAvg	Daily average humidity	Percent
HumidityLow	Daily low humidity	Percent
PressureMaxIn	Daily maximum pressure	mmBars
PressureMinIn	Daily minimum pressure	mmBars
WindSpeedMaxMPH	Daily maximum wind speed	Miles per hour
WindSpeedAvgMPH	Daily average wind speed	Miles per hour
GustSpeedMaxMPH	Daily maximum wind gust speed	Miles per hour
PrecipitationSumIn	Daily total precipitation	Inches
RELEV	Elevation (feet) of nearest grid cell at the ridge crest	Feet
VELEV	Elevation (feet) of nearest grid cell at the valley bottom	Feet
DELTAELV	Change in elevation (feet) between nearest ridge crest and nearest valley bottom. Measure of slope size	Feet
TOTDIST	Total horizontal distance (feet) between nearest valley bottom and nearest ridge crest. Measure of slope size.	Feet
RDIST	Horizontal distance (feet) between grid cell and nearest ridge crest	Feet
VDIST	Horizontal distance (feet) between grid cell and nearest valley bottom	Feet
DEMELV	Elevation (feet) of target grid cell centroid, according to digital elevation model	Feet
ASPECT	Degrees from true north toward which the grid cell faces	Degrees
SLOPE	Percentage slope of grid cell, determined by trend with nearest grid cell in the uphill direction and with the nearest grid cell in the downhill direction. Measures local slope.	Percent

Variable	Description	Units
SLPBIN	Slope values aggregated into bins	Percent
VPLYDIST	Horizontal distance (feet) between grid cell and nearest grid cell along boundary of the closest valley bottom polygon.	Feet
VPLYELV	Vertical distance (feet) between grid cell and nearest grid cell along boundary of the closest valley bottom polygon.	Feet
RPLYDIST	Horizontal distance (feet) between grid cell and nearest grid cell along boundary of the closest ridge top polygon.	Feet
RPLYELV	Vertical distance (feet) between grid cell and nearest grid cell along boundary of the closest ridge top polygon.	Feet
Within slope hazard zone?	Whether grid cell occurs within a ridge saddle, break in slope, or other slope feature determined to be more often used by flying raptors. This determination was judgment based, and not the product of modeling.	1=yes; 0=no
Gross slope	Average slope from nearest valley bottom to nearest ridge crest, measured as ratio of elevation difference and total slope distance.	Ratio (%)
Distance ratio	Ratio of horizontal distance (feet) between grid cell and nearest valley bottom and of distance between grid cell and nearest ridge crest. Values of #DIV/0! in this ratio occurred for grid cells at the ridge crest; repairs were left to the analyst.	Ratio (%)
Elevation ratio	Ratio of vertical distance (feet) between grid cell and nearest valley bottom and of vertical distance between grid cell and nearest ridge crest. Values of #DIV/0! in this ratio occurred for grid cells at the ridge crest; repairs were left to the analyst.	Ratio (%)

Table C-2: Master Data Fields Used in Recording Carcasses Found

Recorded Master Data Fields
Record ID: Unique record identifier for all data rows.
Date: Date that a status check or search took place.
String: Unique identifier for a collection of turbines that trial carcasses were placed and searches occurred.
Species: The species or unknown species determination (ex UNRA, unknown raptor).
Sex: The sex determination of trial carcasses, if known.
Age: The age class of the trial carcass, if known.
Class: The group status of trial carcass, Bird or Bat.
Grid Cell: The dominant grid cell that the carcass occupied on specified date.
Carcass ID: The unique identifier for marked placed trial carcasses, naturally detected carcasses, and unknown marked carcasses.
Assigned ID: The assigned carcass ID for unknown marked carcasses based on proximity to known carcass ID positions and presence status.
P_ID: Identifying number for project field manager who conducted status check, and searcher who conducted search.
Search Outcome: The search outcome, whether a carcass was detected on a day Yes/No.
Presence: The known presence of a carcass on a day Yes/No.
Vegetation height: The vegetation height measure at the position of the carcass.
Scavenger Index: A relative index of carcass condition.
Index 1: A fresh carcass.
Index 2: A partially scavenged or decayed carcass.
Index 3: A completely scavenged or decayed (no remaining edible tissue).
Recorded Master Data Fields
Topo: A topographical feature that the carcass position occupied.
Detection status: The detection outcome generated by a status check or search.
P: Placement of a trial carcass
F: Carcass found
NF: Carcass not found
NC: Carcass position not checked
Detection type: The type of detection (if detected).
S: Found during a standard status check without additional effort.
F: Found during a flushing search around the last known location of a carcass.
I: Found incidentally at an unknown position without a systematic search.
0: Found but not enough evidence to be considered a fatality.
M: Found carcass due to the Marker (FM) or Did Not Find the Marker (NFM).

Source: EcoStat, Inc.

Table C-3: Data Collected by Project Field Managers for Unknown Carcasses

Date	mm/dd/yyyy
Project Field Manager	Project field manager initials.
String	String number.
Start and End Time	24 hour time. Time when the field technician arrived at the string and left after completing the search.
Grid Cell	Alphanumeric cell address indicating the position of the fatality remains.
Species	Project field manager's best understanding of species identification.
Nearest Turbine	The closest complete turbine to the evidence of fatality.
Distance	Distance (in meters) from evidence of fatality to Nearest Turbine.
Bearing	Compass bearing from the Nearest Turbine to the evidence of fatality.
Latitude Longitude	GPS NAD 24 CONUS hddd.ddddd
Carcass sign	One or more code can be entered. Coded categories of carcass sign for evidence of fatality: F = 10 or more feathers W = partial or intact wing or wings T = partial or intact tail PB = body parts or partial body WB = complete whole body H = partial skull or complete head
Photo number	Camera letter and photo numbers.
Vegetation height	The vegetation height (in inches) at the position of the evidence of fatality.
Marked	Yes or No indicating whether the fatality legs and wings were taped or whether the flight feather (wing and tail) were clipped.
Carcass ID	If the legs were taped, the number indicated was recorded.
Scavenger Index	A relative rating of carcass condition: 1 – Fresh 2 – Partially scavenged or decayed 3 – Completely scavenged (feather spots or bones) or very decayed
Notes

APPENDIX D: Figures Illustrating Biases for Equations in the Current Literature

Robert L. Wolpert

The four estimating equations considered here all represent quite similar attempts to estimate the actual number of avian fatalities in a specified area during each of a sequence of time intervals from counts of carcasses. For a variety of reasons some carcasses may not be counted: some may have been removed by scavengers, some may have fallen outside the search region, and searchers may fail to see some carcasses. The four equations differ in the assumptions they make in order to adjust for these missing carcasses.

Two of the estimation equations, those of Erickson, Johnson, *et al.* and of Shoenfeld, assume that search teams will find both "new" carcasses (those killed during the current time period) and "old" ones (those killed during earlier periods, but not removed by scavengers or search teams). Old and new carcasses are assumed to be equally likely to be removed by scavengers, and equally likely to be discovered in a subsequent searches. These estimators will *under*-estimate true mortality if these assumptions are wrong.

Conversely the other two estimation equations, those of Pollock and of Huso, begin with the assumption that *all* carcasses counted are new (*i.e.*, died during the current time interval). Both will *over*-estimate true mortality if this is wrong.

Shoenfeld's estimator always exceeds that of Erickson, Johnson, *et al.*, because the latter assume (incorrectly, in practice) that search teams do not remove carcasses. Huso's estimator is identical[1] to a special case of Pollock's: the case in which scavengers are assumed to remove fresh carcasses and old ones at the same rates (technically, that the "persistence time" before scavengers remove a carcass have "exponential" probability distributions). Pollock's estimator does not require that assumption. For exponential persistence times, the estimators of Erickson, Johnson, *et al.*, Shoenfeld, Pollock, and Huso are ordered consistently

$$\hat{M}_{ij}^{\text{EJ}} < \hat{M}_{ij}^{\text{S}} \quad < \quad \hat{M}_{ij}^{\text{P}} \le \hat{M}_{ij}^{\text{H}}$$

All four give similar estimates when the interval between searches is long compared to mean carcass persistence times, but differences among them are larger when searches are made more frequently to reduce the loss of carcasses to scavenging. With frequent searches, $\hat{M}_{ij}^{\text{P}}$ and $\hat{M}_{ij}^{\text{H}}$ can be as much as three or four times larger than $\hat{M}_{ij}^{\text{S}}$ for small birds. The key issue, then, to guide the choice of estimators, is:

> *What fraction of carcasses missed by a search team might*
> *still be discovered as "old" carcasses in a later search?*

If that fraction is 100% then Shoenfeld's estimator $\hat{M}_{ij}^{\text{S}}$ is most accurate on average if search teams remove the carcasses they discover, and Erickson & Johnson's $\hat{M}_{ij}^{\text{EJ}}$ if they don't.

If that fraction is 0% then Pollocks's estimator $\hat{M}_{ij}^{\text{P}}$ is most accurate on average, with the side benefit that it does not require the "exponential distribution" assumption.

If that fraction is somewhere between 0% and 100%, then some sort of compromise between $\hat{M}_{ij}^{\text{S}}$ and $\hat{M}_{ij}^{\text{P}}$ is called for. Such a compromise is proposed and described in Appendix A, *A New Equation for Estimating Avian Mortality Rates.*

---

[1] Except that Huso's estimator is inflated by about 1% in the rare case when intervals between consecutive searches are more than 4.6 times the average length of time before scavengers remove a carcass.

Figures Illustrating Equation Biases

Figures 1–6 below show eight-week simulations of carcass arrivals and removals by scavengers as stair-step curves increasing at each arrival and decreasing at each removal, with searches at specified intervals from two to 56 days. Carcasses discovered and removed are indicated by downwards pointing red arrows; expected numbers of carcasses are indicated by smooth blue curves.

Figures 1–3 assume exponential distributions for persistence times (so scavengers remove fresh and older carcasses at the same rates), while Figures 4–6 assume Weibull removal distributions with parameter values suggested by our data.

Figures 1, 4 assume that only "new" carcasses can be discovered, so each curve begins each search period with zero carcasses. This assumption underlies Pollock's and Huso's estimators, so their bias is zero in the exponential persistence case, Figure 1 (and, for Pollock, also for Weibull persistence, Figure 4).

Figures 3, 6 assume that 100% of old carcasses remain discoverable, so each curve begins at the point of the red arrow (indicating that carcasses disappear only because of their discovery by search teams). This assumption underlies Erickson, Johnson, *et al.*'s and Shoenfeld's estimators, so Shoenfeld has no bias in Figure 3. Erickson, Johnson, *et al.* still underestimate M_{ij} there because of their assumption that search teams don't remove carcasses.

Finally, figures 2, 5 take the compromise position that (on average) 50% of undiscovered carcasses will remain discoverable; typically here Erickson, Johnson, *et al.*'s and Shoenfeld's estimators will underestimate, while Pollock's and Huso's will overestimate.

Below each of these thirty plots is a table giving the bias (as a percentage of the truth) for each of the four estimators (or five, for Weibull distributions, where results for both exponential and Weibull versions of Pollock's estimator are reported).

All the biases are smaller for long search intervals (at the top of each figure) and greater for shorter ones (at the bottom of each figure). Huso's estimator is identical to the exponential version of Pollock's, and so has the same bias in every case. The new estimator described in Appendix A, *A New Equation for Estimating Avian Mortality Rates*, has zero bias in all of these cases.

Figure Walk-through

Robert L Wolpert

October 26, 2012

1 Introduction

Figure (1) shows two views of the same simulated two-week period, in which fatality occurs at a rate of about one per day and in which weekly searches were made with proficiency $s_{ij} = 30\%$. Carcass persistence is exponentially distributed with mean $t_{ij} = 15\,\mathrm{d}$, and $\theta = 50\%$ of undiscovered carcasses remain across search intervals (those that do *not* remain might be thought to have decayed). Table 1 shows the arrival time and fate of each carcass.

Upper Figure

Each fatality is shown in the upper "Time line" figure as an "×" mark, followed by a horizontal line that indicates the fate of this particular carcass.

Carcasses eventually removed by scavengers are shown in red, with a red dashed red line extending from a red cross "× – –" marking the fatality to an open circle "– – ○" marking the removal. Vertical position in this plot is another indicator of persistence— points are sorted so the carcasses removed most quickly are at the top, those removed most slowly at the bottom (for more on this see *p.* 3 below).

Carcasses eventually discovered in searches are shown as solid black lines, beginning at a black "×—" marking the fatality and ending at one of the weekly search times on days zero, seven or fourteen. Discoveries are marked by black filled circles "—●" for "new" carcasses, *i.e.*, those from the search week, while "old" carcass discoveries are marked with crossed squares "—⊠".

Finally, undiscovered carcasses that become undiscoverable are marked by faint dotted blue lines, beginning at a blue cross "× · · ·" marking the fatality and ending unceremoniously at a search time. We'll discuss the curved lines in the top figure below on *p.* 3.

Lower Figure

The ground "Carcass Count" is shown in the lower figure as a stair-step curve $G(t)$ that indicates the number of discoverable carcasses on the ground at each time t. Between searches, this increases by one with each new fatality and decreases by one with each removal by scavengers. After each search time, $G(t)$ drops by the number of carcasses discovered and removed by the Search Team, which is indicated by a downward red "↓". In addition, some carcasses may "disappear" as they become undiscoverable (or perhaps decay); if so, $G(t)$ will drop further to begin the next period at a value below the red arrow point, indicated by an open square "□". The number possibly discoverable at each search is shown by the filled square "■".

In the bottom figure, the smooth blue curve shows the expected number of discoverable carcasses for the model assumed by the Pollock and Huso estimators— beginning each period with zero carcasses at a blue "○—", then rising smoothly over the period to a peak marked with a blue "—●", then dropping to zero to begin the next period due to those estimators' assumption of "zero carcasses beginning each period", or "no old carcasses". Those curves generally lie below $G(t)$, because their "no old carcass" assumption is false in this simulation, leading estimators $\hat{M}^{\text{P}}_{ij}$ and $\hat{M}^{\text{H}}_{ij}$ of Pollock and Huso to overestimate M_{ij} on average.

A Walk Through This Simulation

This simulation begins at time $t = 0$ with $G(0+) = 2$ discoverable carcasses present, the remnants of the arrivals, removals, and weekly searches from 50 earlier simulated days (not shown) generated to ensure that this two-week period would be typical. Sixteen additional simulated fatalities occurred between days 0 and 14, about what one would expect for an average daily mortality of $m_{ij} = 1/\,\text{d}$.

The first new fatality occurs 0.838 days (20 hours, 7.5 minutes) into the simulation, indicated by a red × at the top left in the upper figure and by the unit increase of $G(t)$ by one (from 2 to 3) in the lower one. The top figure shows that this carcass is eventually removed by scavengers at time $t = 2.015$; this event is indicated in the lower curve by a drop of $G(t)$ from 5 to 4.

$G(t)$ had risen to 5 by time $t = 2.015$ due to the second and third fatalities, which arrived just 41 minutes apart at times $t = 1.27$ and $t = 1.30$, increasing $G(t)$ by one at each event. The earlier of these two is eventually removed by scavengers at time $t = 4.92$, but the latter lasts long enough to be discovered by the Search Team on day seven.

The Day 7 Search

The lower figure shows that $G(7) = 8$ discoverable carcasses were present for the day-7 search, and that three were discovered then (because the red arrow "↓" extends from 8 down to 5). Two of the three discovered carcasses were "new" ones, that arrived at times $t = 1.30$ and $t = 2.41$; the other one was an "old" carcass, that arrived at time $t = -0.17$, four hours and five minutes before the start of our two week-long simulation. Of the five carcasses that were present but not discovered in the day-7 search, two became undiscoverable (on average we would expect $(1 - \theta) = 50\%$ of them to do so), leaving $G(7+) = 3$ discoverable carcasses just after the search to begin the second week.

In the top figure, the two carcasses that become undiscoverable are indicated by blue "× ···" marks beginning at times $t = 3.58$ and $t = 5.90$, and ending with the search at

$t = 7$. That figure also reveals the eventual fate of the other $G(7+) = 3$ carcasses that were present but not discovered in the day-7 search— one of them (the one that arrived at $t = 2.42$) is eventually removed by scavengers at time $t = 13.78$, just before the day-14 search, while the other two eventually became undiscoverable (decayed, perhaps), one on day 14 and one later (on day 21, as it happens).

The Day 14 Search

The search on Day 14 discovered three carcasses, all "new" (having arrived at times $t = 10.50$, 11.77, and 13.23, all in the range $(7, 14]$). Four carcasses were missed in this search: two that arrived just minutes apart at $t \approx 1.43$, which were also both missed in the search on day 7 and both of which are eventually lost to decay, one arriving at $t = 13.23$, also lost to decay; and one (the red $\times --$) arriving at $t = 12.58$, that will eventually be removed by scavengers at time $t = 27.13$ after eluding discovery in both the day-24 and day-21 searches.

The Curves in the Top Figure

Height in the top figure is in fact the "quantile" of the persistence times— so half the arrivals (all marked by $\times$'s) are in the upper half of the figure, 10% in the top (or bottom) tenth, and so on. In fact, the sixteen arrival marks "$\times$" are distributed perfectly evenly (or "uniformly") in the two-dimensional rectangle with height $0 < y < 1$ and width $0 < t < 14$.

The smooth black curves in the upper figure mark the earliest time a carcass can arrive and still be unremoved by scavengers at the next search time. SO, *every* $\times$ outside all the triangular regions marks the arrival of a carcass that will be removed by scavengers before the next search (and so is red), while *every* "$\times$" inside the triangular regions will still be on the ground at the time of at least one search. If it is undiscovered in that search then it still might be removed by scavengers or to decay (and hence some of those marks are red $\times$ or blue $\times$). More frequent searches (smaller values of I_{ij}, here 7) reduce loss to scavenging precisely because they reduce the area outside these triangular regions, but evidently there is a rapidly diminishing return on investment when I_{ij} is reduced far below t_{ij} (here 15 d), because there is little remaining area outside the union of triangles; see Figure 2.

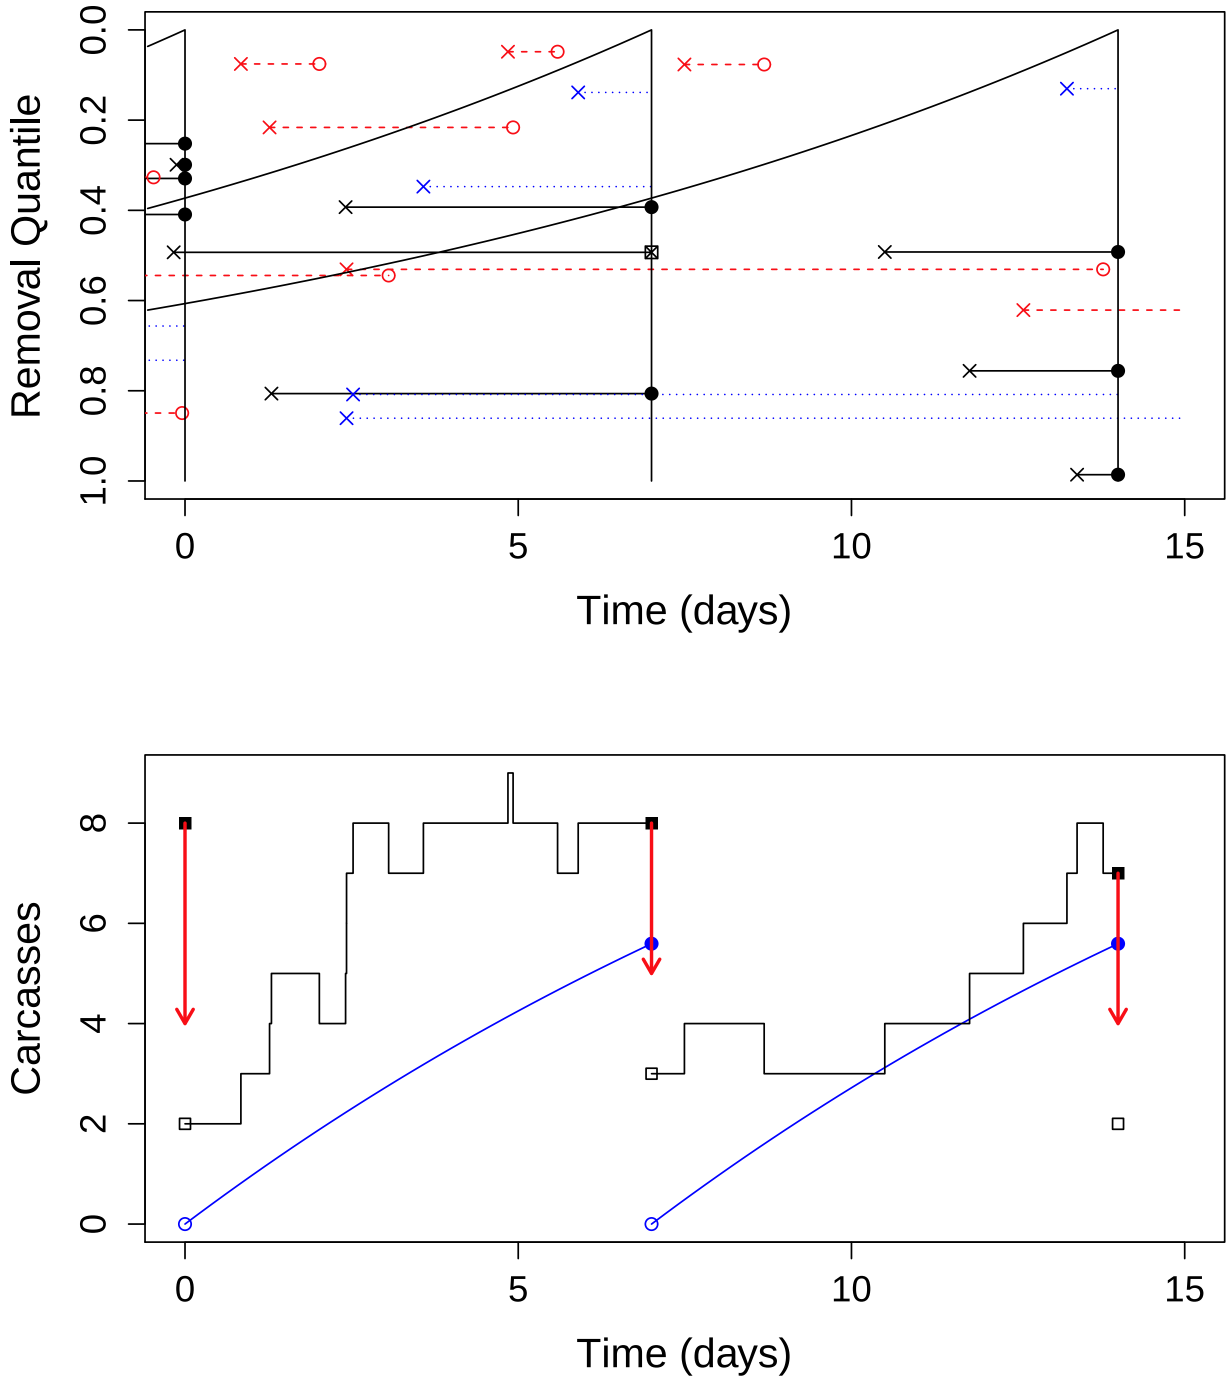

Figure 1: Two graphical views of consecutive one-week searches: Individual time-lines (top), Ground carcass count (bottom). Search proficiency is $s_{ij} = 30\%$; persistence is exponential with mean $t_{ij} = 15\,\mathrm{d}$; $\theta = 50\%$ of undiscovered carcasses remain discoverable for future searches.

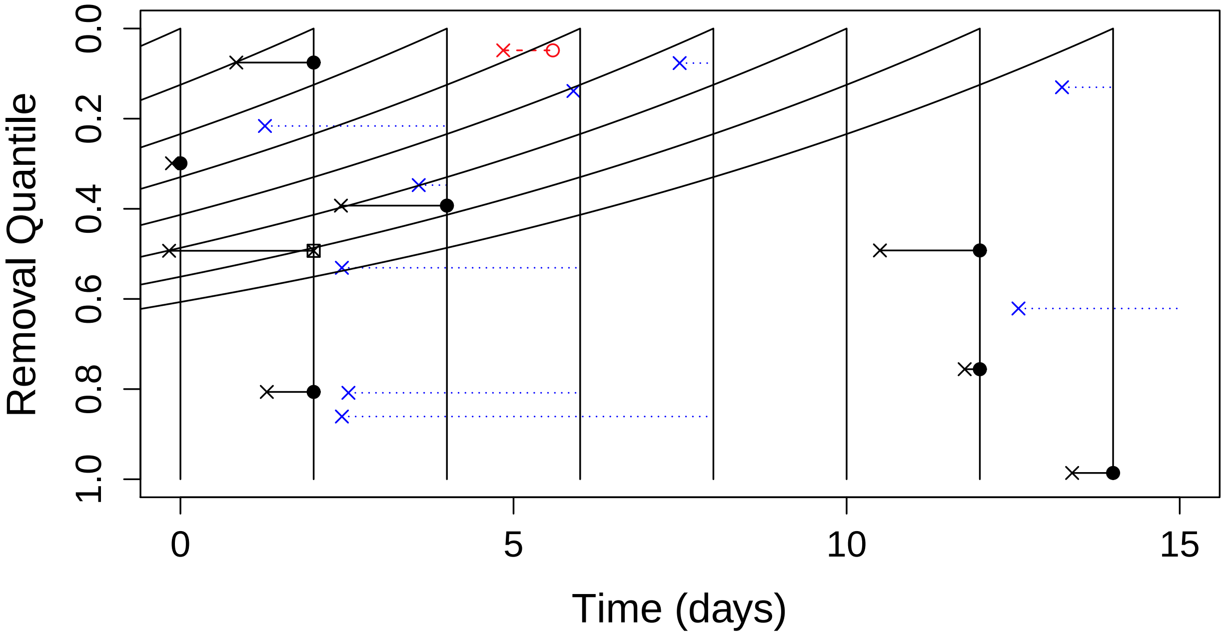

Figure 2: The same simulation, but with $I_{ij} = 2$-day search intervals. Note fewer carcasses lost to scavenging, but only one more discovery (7 in the seven searches on days 2,4,...,14).

CalWEA

Background

- 2007 CEC/CDFG Guidelines
  - *Guidelines for Reducing Bird & Bat Impacts from Wind Energy Development*
- 2008 CEC Research "Roadmap" on Impact Assessment Methods
- 2008 CEC PIER RFP
- 2009 CEC PIER Award to CalWEA
  - Address Guidelines' Appendix F
- 2011 Supplemental FWS Grant to CalWEA

CalWEA

Project Goals

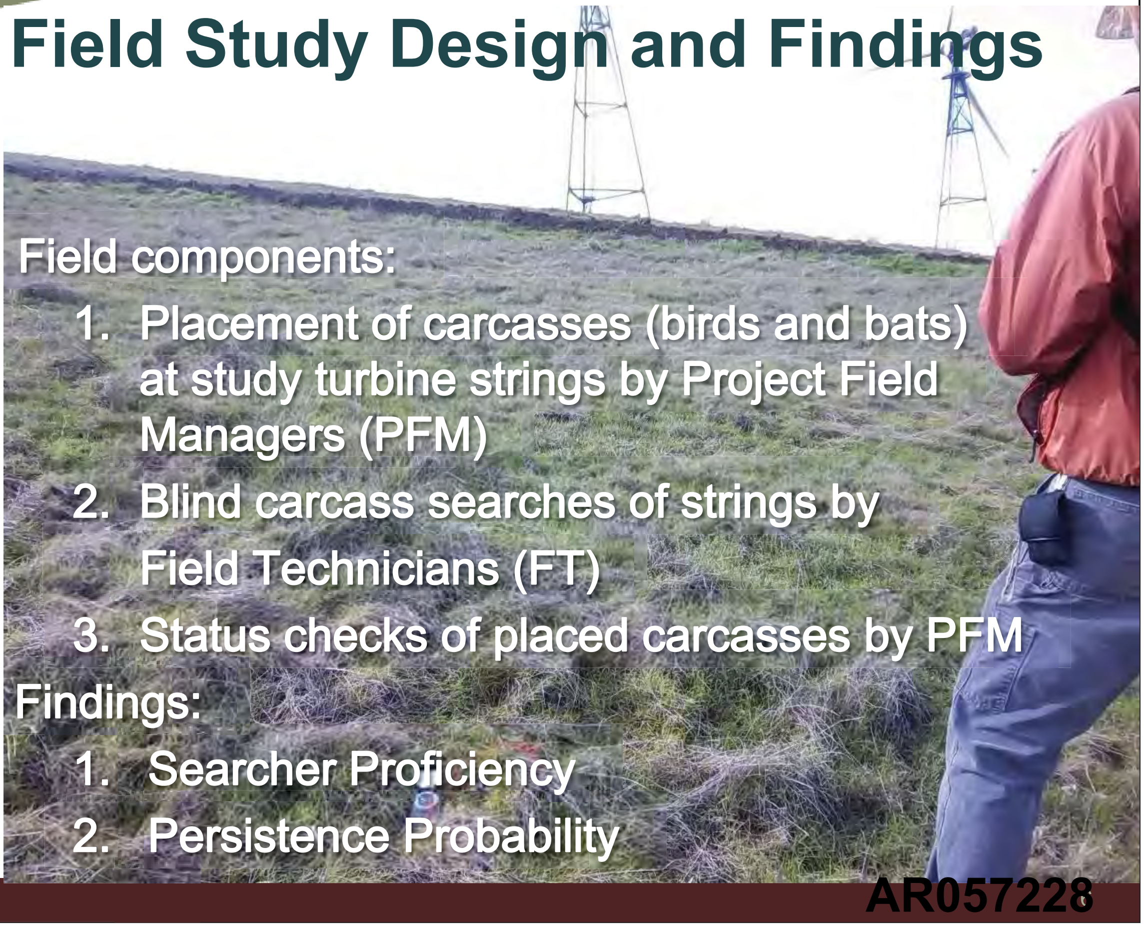
- Improve the accuracy of methods for estimating the number of bird and bat fatalities associated with wind energy facilities
- Provide guidance leading to improved procedures for mortality monitoring at wind energy facilities

Preview of Conclusions

- Fatality estimators in use often produce biased results
- This calls into question the appropriate use of traditional estimators where the error would be of consequence, whether for project-specific results, industry averages, or industry totals
- Standardized methods are needed to generate fatality detection probabilities and fatality estimates
- Our proposed new estimator produces unbiased results, and requires new field protocols

---

Field Study Design and Findings



Field components:

1. Placement of carcasses (birds and bats) at study turbine strings by Project Field Managers (PFM)
2. Blind carcass searches of strings by Field Technicians (FT)
3. Status checks of placed carcasses by PFM

Findings:

1. Searcher Proficiency
2. Persistence Probability

CalWEA

Field Study Design Details

- In all cases, prior to searches the true number and location of carcasses is known to PFMs, but not to FTs
- Each string is searched for up to 60 days, or until all carcasses are removed
- Strings selected to represent various environmental conditions, including grass height, slope, vegetation type
- Carcasses are tagged and followed consistently throughout study period by PFMs

CalWEA

Survey Design Characteristics

- January 7, 2011 – April 1, 2011
- Weekly searches by FTs
- PFMs sampled and noted carcasses approx. every 3 days
- Blocks of strings sampled simultaneously, surrogate for time changes in ecology

Small bird carcasses placed during study	Bat carcasses placed during study	Incidentally found carcasses added to study	Study length (days)
90	78	21	113

FT conducting a search

Field Technician

Searching in tall grass

PFM Status Check

CalWEA

Searching in short grass

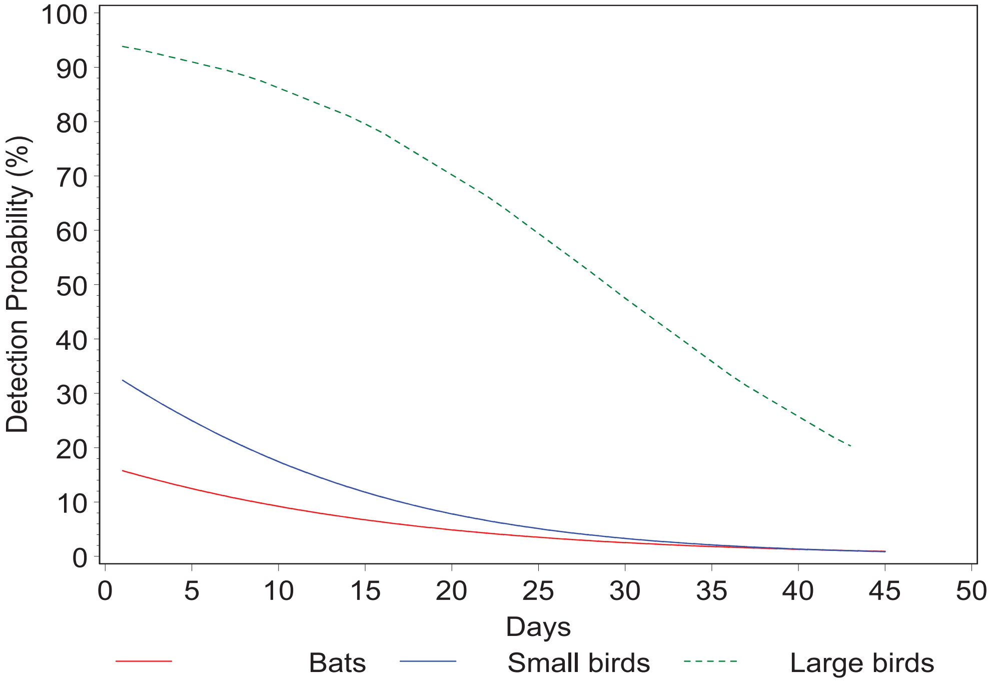
PFM Status Check

CalWEA

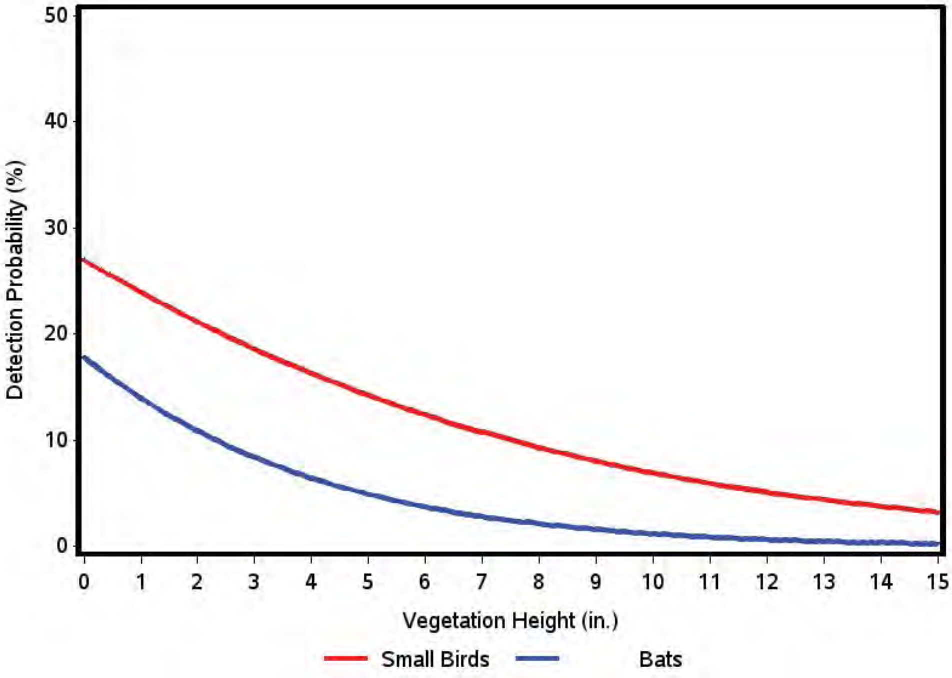
Percent of Birds and Bats Observed

Species	Detected 1st observation	Average detected over all trials for all observers	Unique carcasses detected during study
Bats	14.1%	8.1%	19.2%
Small Birds	22.2%	17.0%	30.8%
Large Birds	83.3%	67.7%	100%

Searcher Proficiency: A Time Dependent Process

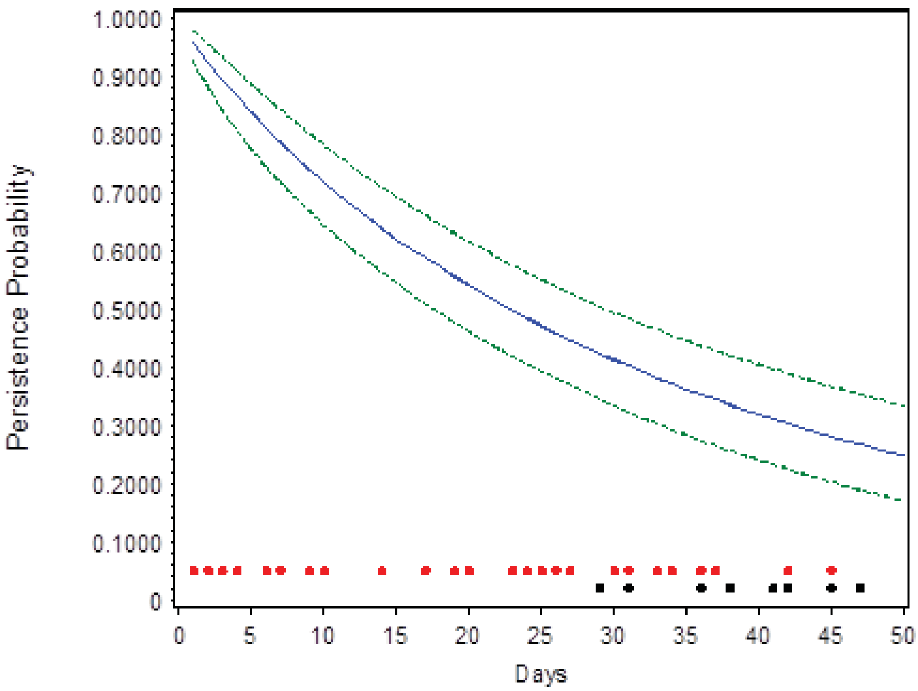


Searcher Proficiency: Dependency on Grass Height



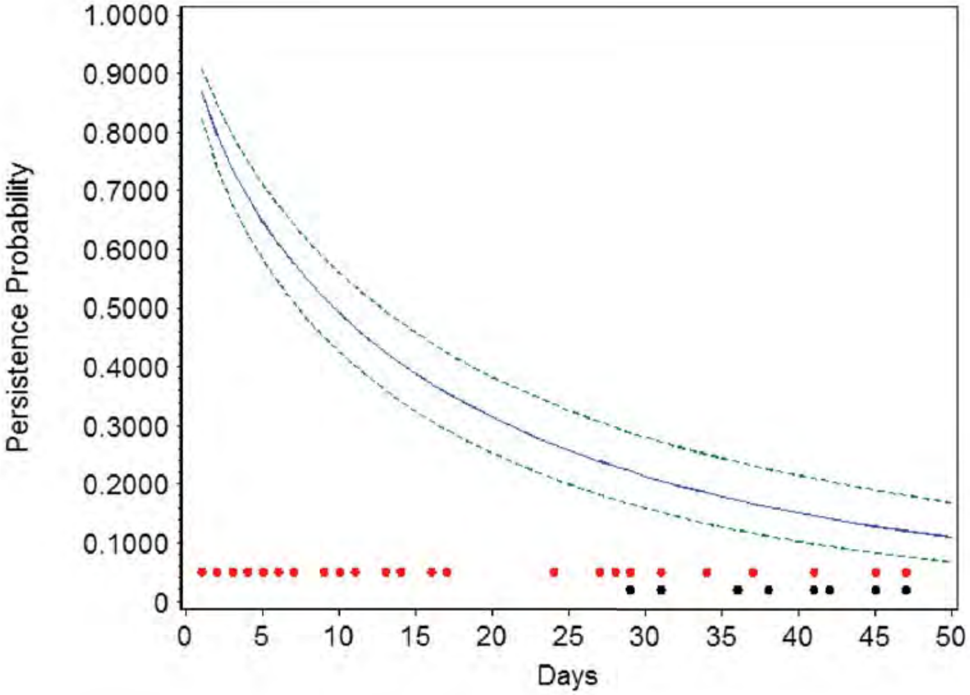
Persistence Probability:

Bats (Weibull Distribution, Mean = 43 days)



Persistence Probability:

Small Birds (Weibull Distribution, Mean = 30 days)



Implications: Field Study

- Carcass persistence is a time-dependent process, fits best with a Weibull distribution
- Searcher proficiency is a function of time
- Ecological conditions impact searcher proficiency (e.g., vegetation height)
- Searcher proficiency for bats is considerably less than for small birds
- Small birds have lower time-dependent persistence than bats
- Above have implications for selection of estimation equation and equation inputs

Partially-Periodic Estimation of Avian Mortality

Robert L Wolpert

Department of Statistical Science *and*
Nicholas School of the Environment
Duke University

CalWEA-CEC Webinar: 2012-09-26

Carcass Counts and Avian Mortality

Let's start with Repeated carcass counts by Field Technicians at regular intervals in specified regions near specific turbines, with:

I_{ij} (interval) = days between successive searches,
M_{ij} (mortality) = number of carcasses during interval,
C_{ij} (count) = number of carcasses counted by FTs,

Naïve estimate "$\hat{M}_{ij} = C_{ij}$" would be okay if:

- A_1: No carcasses at start of interval;
- A_2: Every fatality leads to a carcass;
- A_3: No other carcass sources;
- A_4: Carcasses remain throughout period;
- A_5: Field Technicians find every one.

More realistically...

Several authors have proposed improved estimators to accommodate removal by scavengers and discovery failure, based on one or more of:

p_{ij} (persistence) = probability a carcass is unremoved,
r_{ij} (removal rate) = probability per day of scavenging,
s_{ij} (search proficiency) = discovery probability by FTs,
t_{ij} (persistence time) = mean days carcass unremoved.

Each estimator embodies some assumptions.

Erickson & Johnson

Erickson, Strickland, Johnson, Kern (1998):

$$\hat{M}_{ij}^{\mathrm{EJ}} = \frac{C_{ij}\, I_{ij}}{\hat{s}_{ij}\, \hat{t}_{ij}}$$

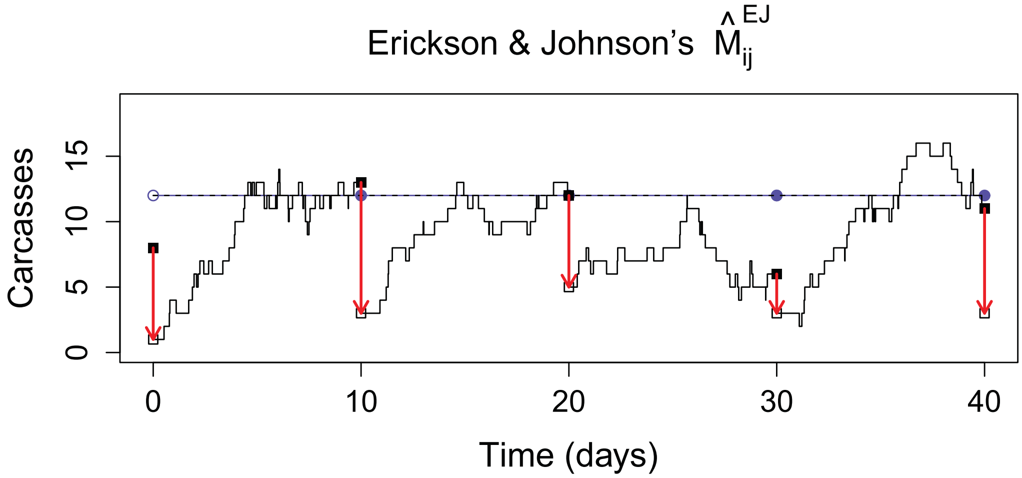
Based on:

$$\mathrm{E}[C_{ij}] = M_{ij}\ (t_{ij}/I_{ij})\ (s_{ij})$$

Assumes:

A_1^{EJ}: The system is in equilibrium at each search.

Erickson & Johnson in Pictures



Shoenfeld's Periodic Equation

Shoenfeld (2004):

$$\hat{M}^{S}_{ij} = \frac{C_{ij}\; I_{ij}}{\hat{s}_{ij}\; \hat{t}_{ij}} \left[\frac{e^{I_{ij}/\hat{t}_{ij}} - 1 + \hat{s}_{ij}}{e^{I_{ij}/\hat{t}_{ij}} - 1} \right]$$

Based on:

$$\mathrm{E}[C_{ij}] = \underbrace{M_{ij}\; (t_{ij}/I_{ij})(1 - e^{-I_{ij}/t_{ij}})\; s_{ij}}_{\text{New}} + \underbrace{\mathrm{E}[C_{ij}]\; (1 - s_{ij})\; e^{-I_{ij}/t_{ij}}}_{\text{Old}}$$

Assumes:

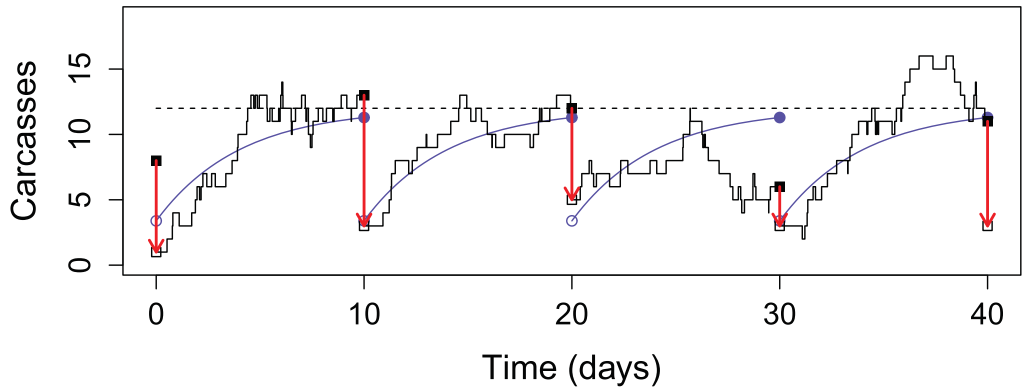
A^S_1: Carcass persistence times have exponential distributions.

A^S_2: New & Old carcasses have same discovery probability s_{ij}

A^S_3: Intervals I_{ij}, mortality and removal rates m_{ij}, r_{ij}, and persistence s_{ij} are similar in consecutive intervals.

Shoenfeld in Pictures

Shoenfeld's $\hat{M}^S_{ij}$



Reflection...

- Both $\hat{M}_{ij}^{\mathrm{EJ}}$ and $\hat{M}_{ij}^{\mathrm{S}}$ assume “100% bleed-through”— Every carcass that is not removed by scavengers, and is not discovered and removed in a search, remains for possible discovery in later searches.
- Shoenfeld also assumes exponential distributions for removal.
- Erickson & Johnson also assume equilibrium, even though FTs remove carcasses discovered in searches.
- Always $\hat{M}_{ij}^{\mathrm{EJ}} < \hat{M}_{ij}^{\mathrm{S}}$, with small differences if $I_{ij} \gg t_{ij}$:

$$\hat{M}_{ij}^{\mathrm{EJ}} < \hat{M}_{ij}^{\mathrm{S}} = \hat{M}_{ij}^{\mathrm{EJ}}\left[1 + \frac{s_{ij}}{e^{I_{ij}/t_{ij}} - 1}\right]$$

Estimators without bleed-through

Perhaps *none* of the “Old” carcasses that were

- Not removed by scavengers, and
- Not discovered & removed by FTs

are ever discovered in subsequent searches.

If so, we can remove the bleed-through part from Shoenfeld’s equation to get a new estimator:

Huso's Equation

Huso (2011) proposed:

$$\hat{M}^{\mathrm{H}}_{ij} = \begin{cases} \dfrac{C_{ij}\, I_{ij}}{\hat{s}_{ij}\, \hat{t}_{ij}\left(1-e^{-I_{ij}/\hat{t}_{ij}}\right)} & I_{ij} < \hat{I}_{ij} \\ \dfrac{C_{ij}\, I_{ij}}{\hat{s}_{ij}\, \hat{t}_{ij}\left(1-e^{-\hat{I}_{ij}/\hat{t}_{ij}}\right)} & I_{ij} > \hat{I}_{ij} \end{cases}$$

Based on:

$$\mathrm{E}[C_{ij}] = M_{ij}\ (t_{ij}/I_{ij})(1-e^{-I_{ij}/t_{ij}})\ s_{ij}$$

Assumes:

$\mathrm{A}^{\mathrm{H}}_{1}$: Each period begins with no discoverable carcasses.

$\mathrm{A}^{\mathrm{H}}_{2}$: Persistence times have exponential distributions.

Huso's Equation

Huso (2011) proposed:

$$\hat{M}^{\mathrm{H}}_{ij} = \frac{C_{ij}\, I_{ij}}{\hat{s}_{ij}\, \hat{t}_{ij}\left[0.99 \wedge (1-e^{-I_{ij}/\hat{t}_{ij}})\right]}.$$

Based on:

$$\mathrm{E}[C_{ij}] = M_{ij}\ (t_{ij}/I_{ij})(1-e^{-I_{ij}/t_{ij}})\ s_{ij}$$

Assumes:

$\mathrm{A}^{\mathrm{H}}_{1}$: Each period begins with no discoverable carcasses.

$\mathrm{A}^{\mathrm{H}}_{2}$: Persistence times have exponential distributions.

Huso's Equation

Huso (2011) proposed a slight variation on:

$$\hat{M}^{\mathrm{H}}_{ij} \approx \frac{C_{ij}\, I_{ij}}{\hat{s}_{ij}\, \hat{t}_{ij}\, (1 - e^{-I_{ij}/\hat{t}_{ij}})}.$$

Based on:

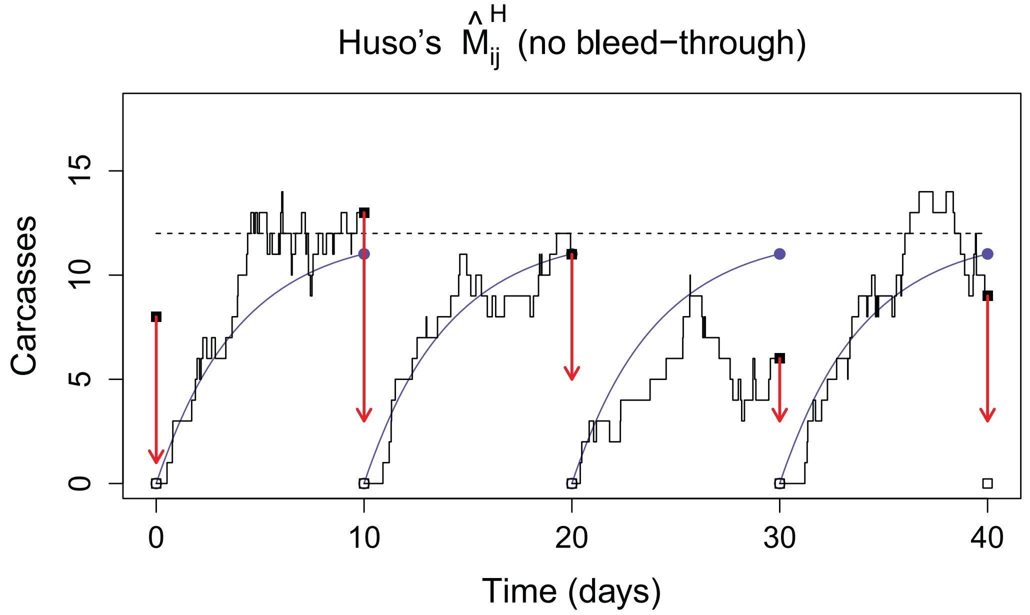
$$\mathrm{E}[C_{ij}] = M_{ij}\ (t_{ij}/I_{ij})(1 - e^{-I_{ij}/t_{ij}})\ s_{ij}$$

Assumes:

$\mathrm{A}^{\mathrm{H}}_1$: Each period begins with no discoverable carcasses.

$\mathrm{A}^{\mathrm{H}}_2$: Persistence times have exponential distributions.

Huso in Pictures



Pollock's Estimator

Pollock (2007) based an estimator on "average probability a carcass is unremoved until the search" p_{ij}, instead of more commonly used mean persistence time t_{ij}:

$$\begin{aligned}\hat{M}^{\mathrm{P}}_{ij} &= \frac{C_{ij}}{\hat{s}_{ij}\,\hat{p}_{ij}} && \text{(any dist'n)}\\ &= \frac{C_{ij}\,I_{ij}}{\hat{s}_{ij}\,\hat{t}_{ij}}[1-e^{-I_{ij}/\hat{t}_{ij}}]^{-1} && \text{(w/Expon.)}\\ &= \frac{C_{ij}\,I_{ij}}{\hat{s}_{ij}\,\hat{t}_{ij}}\,P\big(\tfrac{1}{\alpha},\ [\Gamma(1+\tfrac{1}{\alpha})I_{ij}/\hat{t}_{ij}]^{\alpha}\big)^{-1} && \text{(w/Weibull)}\end{aligned}$$

Based on:

$$\mathrm{E}[C_{ij}] = M_{ij} \ \times\ p_{ij}\ \times\ s_{ij}$$

Assumes:

$\mathrm{A}^{\mathrm{P}}_{1}$: Each period begins with no discoverable carcasses.

More reflection...

- Both $\hat{M}^{\mathrm{H}}_{ij}$ and $\hat{M}^{\mathrm{P}}_{ij}$ assume "0% bleed-through"— "Old" carcasses are never discovered.
- Huso also assumes exponential distributions for removal.
- Pollock's equation can be instantiated for any specific removal distribution, or used in "raw" form with direct empirical estimates of $\hat{p}_{ij}$.
- For exponential removal,

$$\hat{M}^{\mathrm{EJ}}_{ij} < \hat{M}^{\mathrm{S}}_{ij} \quad < \quad \hat{M}^{\mathrm{P}}_{ij} = \hat{M}^{\mathrm{H}}_{ij}$$

(unless $I_{ij} > 4.6t_{ij}$, when $\hat{M}^{\mathrm{H}}_{ij}$ is 1% bigger than $\hat{M}^{\mathrm{P}}_{ij}$)

Do the differences matter?

- If $I_{ij} \gg t_{ij}$ (That is, if search intervals are long compared to mean persistence times), Then NO, all four estimators give about the same answers.
- BUT, they differ substantially under more frequent sampling.
- For typical search proficiencies of $25\% < s_{ij} < 60\%$,

If $I_{ij} \approx 2t_{ij}$, $\hat{M}_{ij}^{\mathrm{EJ}}$ is 4– 9% lower than $\hat{M}_{ij}^{\mathrm{S}}$

$\hat{M}_{ij}^{\mathrm{H}} = \hat{M}_{ij}^{\mathrm{P}}$ is 6–11% higher;

If $I_{ij} \approx t_{ij}$, $\hat{M}_{ij}^{\mathrm{EJ}}$ is 13–26% lower than $\hat{M}_{ij}^{\mathrm{S}}$

$\hat{M}_{ij}^{\mathrm{H}} = \hat{M}_{ij}^{\mathrm{P}}$ is 17–38% higher;

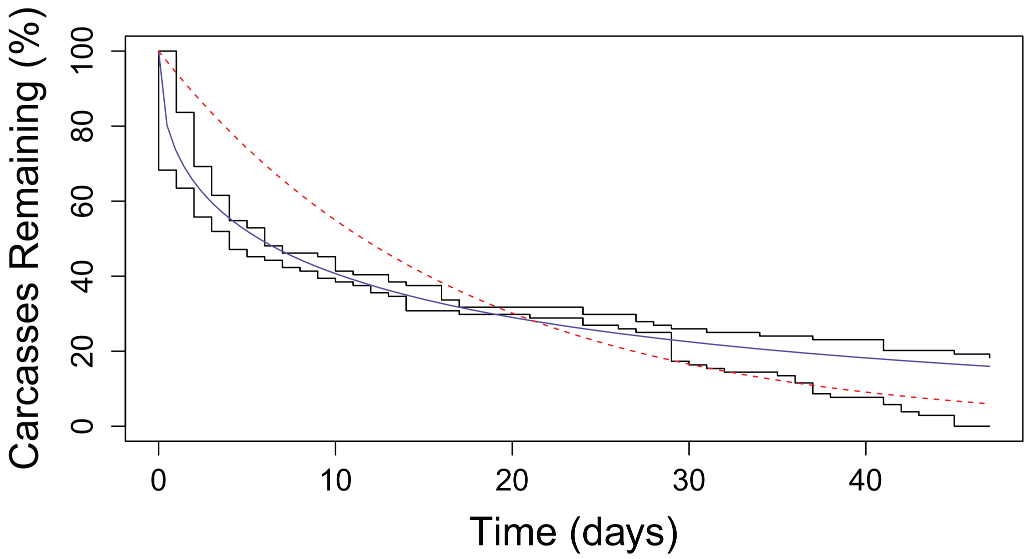
If $I_{ij} \approx \frac{1}{2}t_{ij}$, $\hat{M}_{ij}^{\mathrm{EJ}}$ is 28–48% lower than $\hat{M}_{ij}^{\mathrm{S}}$

$\hat{M}_{ij}^{\mathrm{H}} = \hat{M}_{ij}^{\mathrm{P}}$ is 32–83% higher

- No matter how short I_{ij} is, $\hat{M}_{ij}^{\mathrm{S}}$ is never more than s_{ij} times smaller than $\hat{M}_{ij}^{\mathrm{H}} = \hat{M}_{ij}^{\mathrm{P}}$ (at most a factor of 3 or 4).

Are the Assumptions True?

Exponential persistence?



Are the Assumptions True?

Exponential persistence?

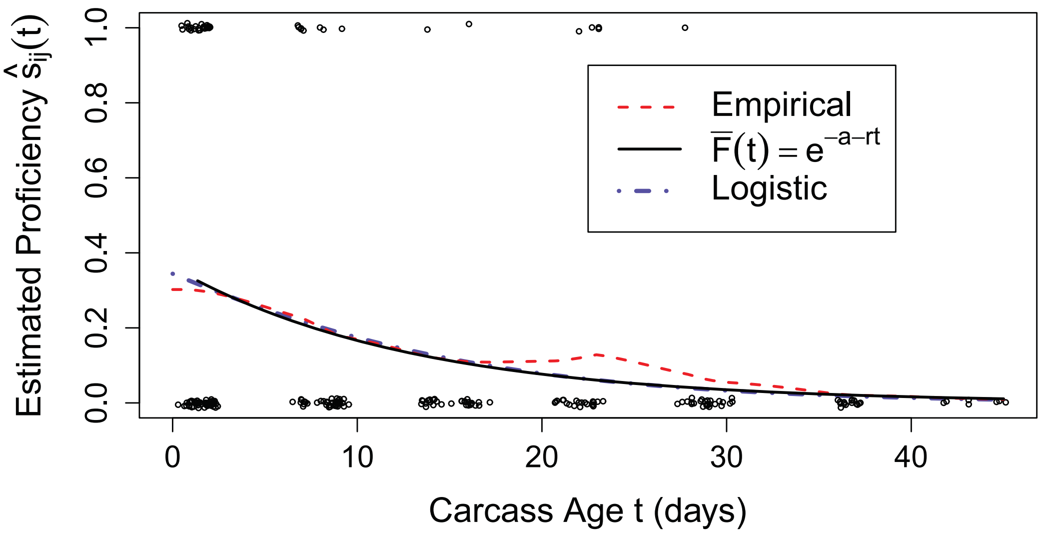
- Weibull, Lognormal, Fisk (Log-logistic) distributions *all* fit data far better than Exponential.
- Ex(λ) is the special case "$\alpha = 1$" of We(α, λ)
- Maximum Likelihood Estimate of α for small birds was

$$\hat{\alpha} = 0.4606, \text{ Standard Error} = 0.0532$$

- MLE is 10.14 SEs away from Exponential Dist'n ($\alpha = 1$)... *P*-value is 1.8×10^{-24}, far below 0.05.
- Higgs Boson discovery claim was based on 5 SE difference.

Are the Assumptions True?

Constant Proficiency s_{ij}?



Zero bleed-through? 100% bleed-through?

- For long search intervals, bleed-through doesn't matter.
- For short search intervals, probably some old carcasses are discovered.
- Falling search proficiency with carcass age ameliorates this—old carcasses are less likely to be found.
- None of the existing estimators reflects falling s_{ij}.

A note about "Mean Persistence Time" t_{ij}

- Most estimators depend on estimates of average time t_{ij} until removal by scavengers.
- This is a hard thing to estimate, because of censored observations and heavy tails.
- If persistence really had exponential distributions it wouldn't matter... but evidence shows that's wrong.
- Methods recommended in the literature systematically underestimate t_{ij}.
- The relation between daily removal rates and t_{ij} is highly model-dependent.

Something New: A Unified Partially-Periodic Estimator

$$\hat{M}^{\star}_{ij} = \frac{C_{ij}\, l_{ij}}{\hat{s}_{ij}\ \hat{t}_{ij}} \left\{ \frac{e^{l_{ij}/\hat{t}_{ij}} - \theta(1-\hat{s}_{ij})}{e^{l_{ij}/\hat{t}_{ij}} - 1} \right\},$$

with “bleed-through” parameter $0 \le \theta \le 1$. Special cases:

- $\theta = \mathbf{0}$: Identical to estimator of Huso and Pollock
- $\theta = \mathbf{1}$: Identical to estimator of Shoenfeld
- $\theta = \frac{\mathbf{1}}{\mathbf{1-s_{ij}}}$: Identical to estimator of Erickson & Johnson

For values $0 < \theta < 1$, this interpolates among them.

Based on:

$$\mathsf{E}[C_{ij}] = M_{ij}\ (t_{ij}/l_{ij})(1 - e^{-l_{ij}/t_{ij}})\ s_{ij} + \quad \theta \quad \mathsf{E}[C_{ij}]\ (1 - s_{ij})\ e^{-l_{ij}/t_{ij}}$$

But...

- This form of the Partially Periodic Estimator allows one to overcome the bleed-through problem, but
- It still assumes exponential distributions (as do Shoenfeld’s and Huso’s estimators)
- It still assumes constant search proficiency (as do all four previous estimators)

- Something better is needed.

Something Better

A new estimator based on the assumptions:

- Declining removal rate achieved through Weibull We(α, r) persistence distribution

$$\mathrm{P}[\tau > t] = e^{-(r\,t)^{\alpha}}$$

  for some parameters $0 < \alpha \leq 1$, $r > 0$;
- Diminishing proficiency

$$s_{ij}\,(t_k) = e^{-a-b\,t_k}$$

  where t_k denotes the "age" of kth carcass
- Partial periodicity, with a fraction $0 \leq \theta \leq 1$ of remaining carcasses still discoverable
- Parameters (α, r), (a, b), θ are estimated in Detection Probability Trials designed to accommodate censoring.

The New Estimator:

$$\hat{M}^{\star}_{ij} = \frac{C_{ij}\,I_{ij}}{R^{\star}_{ij}}$$

where C_{ij} is the Carcass Count, I_{ij} is Interval Length and, for $\theta = 0$ (no bleed-through, as in Huso and Pollock), and $R^{\star}_{ij}$ is the *adjusted* (for diminished search proficiency) *remainder factor*:

$$R^{\star}_{ij} = \int_0^{I_{ij}} \exp\Big(-(r_{ij}\;x)^{\alpha} - a - bx\Big)\,dx$$

Easily calculated on a computer— or, for $\alpha \approx 1/2$ as in our small bird data, available explicitly as

$$\begin{aligned} R^{\star}_{ij} &= Q^{\star}(0; a, b, r_{ij}) - Q^{\star}(I_{ij}; a, b, r_{ij}), \quad \text{where} \\ Q^{\star}(x; a, b, r) &= \exp\big(-a - bx - \sqrt{rx}\big)/b \\ &\quad - e^{-a+r/4b}\,\Phi\Big(-\sqrt{2bx} - \sqrt{r/2b}\Big)\sqrt{\pi r/b^3}. \end{aligned}$$

Summary

New estimator:

- Includes as special cases those of Erickson & Johnson, Shoenfeld, Huso, and Pollock,
- Extends to **Partially Periodic** case of $\theta > 0$,
- Allows exponential or more realistic **Weibull** persistence times with **declining removal rate**,
- Allows constant or more realistic **dimishing proficiency**,
- Is not much harder to use than existing ones, after an **integrated detection trial** to estimate the five parameters
  (α, r) (for persistence distribution),
  (a, b) (for proficiency), and
  θ (for bleed-through).

Suggestions:

- For short intervals $I_{ij} \ll t_{ij}$, bleed-through θ is important—getting it wrong will distort estimates (up *or* down).
- For long intervals $I_{ij} \gg t_{ij}$, diminishing proficiency $s_{ij}(t)$ is important. So is declining removal rate: use Weibull or Log Normal or Log Logistic removal distributions, *not* exponential.
- For moderate intervals $I_{ij} \approx t_{ij}$ and search proficiencies s_{ij}, ratios among estimators are no worse than about 3:2.
- All these issues (bleed-through, diminishing proficiency, declining removal rate) can be addressed with a modest increase in complexity with a **partially periodic estimator** and a suitable **integrated detection probability trial**.

CalWEA

Summary: Model Comparison

Model Characteristics

- Contrasting with lessons from the field work:
  - All models assume constant searcher proficiency
  - Some models assume an exponential distribution (fresh and older carcasses equally attractive to scavengers)
- Some models assume bleed-through (Shoenfeld), some don’t (Huso, Pollock), and E&J assume equilibrium

---

CalWEA

Summary: Model Comparison

- For exponential removal:

  Erickson & Johnson < Shoenfeld < Pollock < Huso

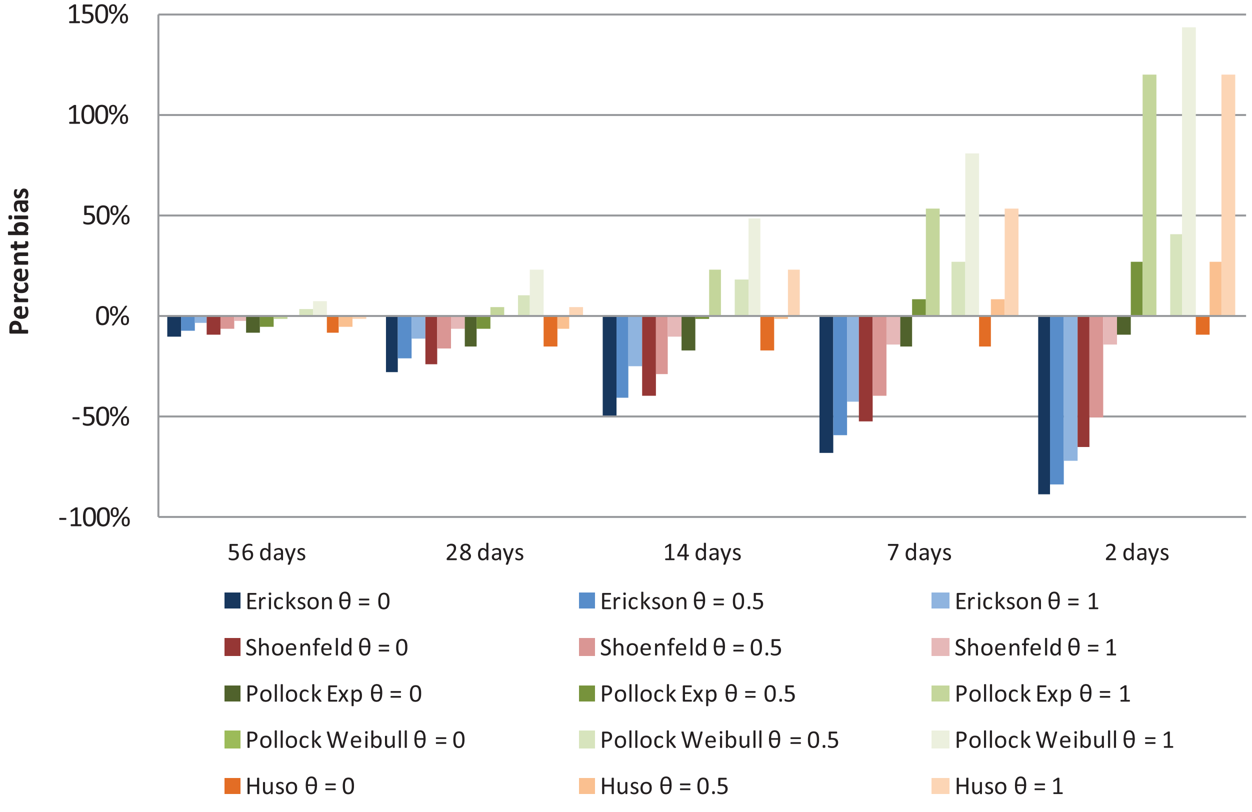
- Even though biased, if search interval is long compared to mean persistence time:
  - **All 4 estimators give about the same results**
- But, if search interval is short relative to persistence:
  - **Differences among equations increase**

Are Short Search Intervals Useful?

- Short search intervals increase chance of bias
  - Short intervals do not allow system to reach equilibrium, inconsistent with E&J assumption
  - Huso and Pollock assume 0% bleed-through, therefore bias will occur if bleed-through is more
  - Shoenfeld assumes 100% bleed-through, therefore bias will occur if bleed-through is less
- New partially-periodic equation allows for any bleed-through, therefore works very well with short or long intervals

---

Comparison of Bias in Estimators at Various Search Intervals and "Bleed-Through" θ Assumptions with Removal Distribution α = 0.7



Recommendations

Given the shortcomings of traditional estimators …

Traditional fatality estimators do not sufficiently account for

- Time-dependent processes of carcass persistence and searcher proficiency, and
- “Bleed-through” (the portion of carcasses persisting through a search interval that can be detected in subsequent search interval)

… CalWEA’s Research Team developed and recommends:

- New fatality estimator (“partially-periodic” presented above), and
- Integrated detection probability trial methodology

Why Traditional Detection Trials Won’t Work

- Traditional Searcher Proficiency Trials
  - Only fresh carcass detection events
  - One day trials
- Traditional Carcass Persistence Trials
  - No way of measuring bleed-through

Requirements for a New Integrated Detection Probability Trial

1. A preliminary traditional carcass persistence trial
2. Strategic placement of trial carcasses
3. Traditional schedule of carcass checks, with additional checks on the same day as scheduled searches
4. Searchers record detected trial carcasses over multiple search intervals
5. Measure the proportion of carcasses that persist (bleed-through) from one search interval to the next to derive the term theta

Analytical Products Gained From New Integrated Detection Trial

1. Time dependent probabilities for carcass persistence and searcher proficiency
2. A measurement of theta (bleed-through)
3. Traditional fatality estimator parameters are conserved

CalWEA

Conclusions

Policy Decision Implications

- Potentially faulty fatality estimates are being used in decision-making
- Are the errors of consequence?
  - Accuracy vs. precision
- Caution is required …

CalWEA

Conclusions

Policy Decision Implications

- Caution needed in determining:
  - National avian and bat mortality
  - Industry averages
  - Regulatory standards for monitoring
  - Numerical “thresholds” for post-construction monitoring and adaptive management requirements
- Caution needed when comparing:
  - Specific project results to national industry averages
  - Intra-project results where study approaches have differed
  - Results among wind facilities
- What degree of accuracy and precision is needed?

Conclusions

Study Design Implications

- To generate accurate and comparable fatality detection probabilities and fatality estimates
  - Uniform, standardized methods are needed
  - Partially periodic equation produces unbiased results
  - New equation requires new field study protocols

Final Thoughts & Questions

SECTION 1.0 – INTRODUCTION

The Centinela Solar Energy Project (CSE Project) includes the construction, operation, and maintenance of a solar electric power generating facility and associated electrical line on private and federal lands in southern Imperial County, California. The Post-Construction Bird and Bat Conservation Strategy (BBCS) addresses the implementation of a post-construction avian mortality monitoring program to evaluate whether anticipated baseline impacts on avian species are consistent with actual outcomes on a San Diego Gas & Electric (SDG&E) managed portion of the CSE Project (CSE BBCS Project). The purpose of the CSE BBCS is to implement a program to identify and avoid risks to avian and bat species that could result from post-construction activities and maintenance of the CSE Project. The goal of this CSE BBCS Project is to implement a series of best management practices in order to operate the CSE Project to avoid or reduce risk to birds, bats, and their habitats. The CSE BBCS Project includes post-construction monitoring intended to facilitate documentation of avian mortalities that might occur and to identify factors associated with avian mortalities. The BBCS requires implementation of the proposed monitoring program and will assist the United States Fish and Wildlife Service (USFWS) and U.S. Department of the Interior Bureau of Land Management (BLM) to evaluate the effectiveness of the avoidance, protection, and minimization measures. This report is intended to provide an annual report of post-construction monitoring for avian mortalities along the portion of the generation-interconnection (gen-tie) electric line currently owned and operated by SDG&E.

1.1 PROJECT DESCRIPTION

The BLM El Centro Office approved Alternative 3 of the CSE Project EIR/EA on December 15, 2011 (BLM 2011). The general location of the CSE Project is the Mount Signal area of Imperial County, approximately eight miles southwest of the city of El Centro, Imperial County, California (Figure 1). The CSE Project consists of an approximately 2,067-acre solar electric power generating facility (CSE Facility) and double-circuit, 230 kilovolt (kV), overhead electrical line (gen-tie line) that will connect to the Imperial Valley Substation (IV Substation) on federal land managed by the BLM (Figure 1). The CSE Facility and gen-tie line are collectively referred to as the CSE Project.

The CSE Facility site is comprised of approximately 2,067 acres of private land. The Applicant controls the CSE Facility site through a combination of options to purchase and lease agreements and fee ownership by an affiliate. Major features of the CSE Facility site includes a photovoltaic (PV) array field, substation, switchyard, earthen storm water retention and detention basins, access roads, perimeter fencing and a common service area that includes support buildings and maintenance facilities. The gen-tie line originates at the CSE Facility substation, located immediately south of Highway 98 and approximately 0.5 mile east of Pulliam Road, and extends approximately 1.5 miles generally west through the CSE Facility site. From the western boundary of the CSE Facility site, the gen-tie line continues west across the Westside Main Canal and through private agricultural lands south of Highway 98. The BLM right-of-way (ROW) for the gen-tie line encompasses the segment from Mount Signal Road south of Highway 98 and traverses approximately 1.25 miles of native desert west and then north to a location just north of Highway 98, where the gen-tie line crosses under the existing 230kV lines and interconnects with a radial line owned by SDG&E, providing an electrical connection to the IV Substation (230-kV interconnect). The gen-tie line includes the constructed Drew Switchyard on the CSE Facility site east of the Westside Main Canal, and both sides of the double-circuit structures between the Drew Switchyard and the connection to the SDG&E radial line that was utilized by CSE to construct the “loop-in.” The gen-tie line design consists of double-circuit, tubular steel monopole structures, with tubular steel H-frame and three-pole dead-end structures at the undercrossing location. Typical tower structure heights range from 100 to 130 feet. Each side of the double-circuit structures will support three two-bundle conductors and one shield wire. Typical overall structure widths are approximately 20 feet for the double-circuit structures.

The portion of the CSE Project that SDG&E is responsible for monitoring as part of the CSE BBCS Project consists of the approximately 2.5-mile portion of the gen-tie line from Drew Switchyard to the 230kV interconnect. Upon the conclusion of construction of the CSE Project, operation and maintenance associated with the 2.5-mile gen-tie line became the responsibility of SDG&E. Ownership of the gen-tie line from the Drew Switchyard to the 230kV interconnect was transferred to SDG&E following construction in September 2013. Upon transfer of these assets, SDG&E assumed responsibility for monitoring the approximately 2.5-mile gen-tie line to comply with the terms of the CSE BBCS, Section 6, Post-construction Monitoring.

1.2 POST-CONSTRUCTION MONITORING

Section 6 of the CSE BBCS necessitates the implementation of a post-construction avian mortality survey program. Post-construction monitoring is designed to evaluate whether anticipated baseline impacts on avian species are consistent with actual outcomes.

During the year one survey (October 2013 – September 2014), post-construction mortality monitoring occurred over the first seven days of each month. Monitoring occurred by transect, with portions of the line that were sampled accounting for at least 20 percent coverage of the gen-tie line managed by SDG&E. Information was collected for all mortalities observed including: Universal Transverse Mercator (UTM) location, species, sex, age, distance from nearest CSE BBCS Project component, bearing from nearest CSE BBCS Project component, observable injuries, surrounding habitat, and photos.

Following discussion with BLM and USFWS in February 2015, the year two post-construction mortality monitoring study design was modified beginning March 2015, to include surveys twice weekly with no more than three days occurring between surveys. To capture additional data, the year two survey period was extended to 15 months (October 2014 – December 2015). Similar to the year one survey, monitoring occurred along the 1.25 miles of the creosote scrub habitat portion of the line from Mount Signal Road north to the 230kV interconnect, located on BLM land (Survey Area). The modified design increased the Survey Area to include 50 percent coverage of the gen-tie line managed by SDG&E, representing an increase of 100 percent from year one of the study. Information collected for all mortalities observed followed that of year one of the study. Per guidelines outlined in Section 6 of the CSE BBCS, data collected during the post-construction avian mortality surveys will be used for two primary analyses using the statistical software programs DISTANCE and MARK: (1) estimate the most effective transect survey width to search for carcasses and (2) estimate total avian mortality on the gen-tie line during the 15-month period beginning October 2014 and ending December 2015.

1.3 STUDY BACKGROUND

Avian collisions with man-made structures are estimated to be one of the leading causes of non-natural death of birds worldwide. Estimates of avian collisions and mortalities with electrical power lines are lacking and very challenging to determine due to the variety of biases. Detection and reporting of avian line strikes vary due to observer detection bias, scavenger removal, habitat type, crippling bias, and seasonal abundance (Rioux et. al 2013). The CSE BBCS Project will provide valuable data on the impacts of this 230kV gen-tie within this arid desert region of southeastern California.

Collision events are rarely directly observed in the field, thus the best method for measuring collision rates is for trained observers to search for carcasses (Rioux et. al. 2013). Detection biases have been carefully considered during the design modification of the CSE BBCS. Observer detection bias can vary depending on weather, habitat conditions, and carcass size. The selected study area is comprised of creosote scrub habitat characterized by low vegetation ground coverage and low height. Additionally, the Survey Area is within the Yuma desert which experiences favorable weather conditions for detecting avian line strikes. Due to favorable observation conditions, it was not anticipated that observer bias would have significant impact on detection of avian line strikes. Observer bias studies were conducted during year one only. The observed bias studies resulted in 93 percent detection of placed objects. The observer bias studies are addressed further in Section 2 and Section 3.

Scavenger removal of carcasses is a potentially serious bias in desert conditions. High visibility of carcasses to both mammal and avian scavengers in the desert environment means scavenger removal rates may be high at the selected Survey Area. Additionally, anticipated increases in scavenger abundance (e.g., nesting by scavengers such as common ravens, loggerhead shrikes, and raptors during the spring months) is expected to coincide with seasonal changes in avian abundance (spring migration), further confounding the bias. It is anticipated that scavenger removal rate will have a significant impact on detection of avian line strikes and is addressed further in Section 2 and Section 3.

SECTION 2.0 – METHODS

2.1 SELECTION OF STUDY AREA FOR INCREASED DETECTIONS

The portion of the CSE Project that SDG&E is responsible for monitoring as part of the CSE BBCS Project consists of the approximately 2.5-mile portion of the gen-tie line from the constructed switchyard (Drew Switchyard) to the 230-kV interconnect (Figure 2). From the Drew Switchyard, the gen-tie line extends east through 1.25 miles of agricultural lands followed by 1.25 miles of creosote scrub habitat, terminating at the boundary of the existing SDG&E north-south, 230-kV ROW. However, executing the CSE BBCS within the area described above, specifically the private agricultural land located on the eastern half of the gen-tie line, posed several complications with regard to data collection, survey replication, land access, confounding variables, and surveyor safety. As such, during year one of the study, 20 percent of the 2.5-mile gen-tie was selected for study within the 1.25 miles of creosote scrub habitat located on BLM land on the western half of the CSE BBCS Project area. During review of survey efforts from October 2013 to February 2015, it was determined by USFWS and BLM to redesign the survey protocol to increase probability of avian line strike detections to fulfill the requirements of CSE BBCS. The survey area was redefined beginning March 2015 to include the full 1.25 miles of creosote scrub habitat located west of Mount Signal Road, beginning at the Drew Switchyard and extending west and north to the 230-kV interconnect (Figures 2 and 3), to account for 50 percent coverage of the entire gen-tie line. The modified Survey Area extends 2,012 meters along the centerline and buffers out 20 meters on either side of the centerline. In addition, the timing of the surveys were modified from occurring during the first seven days straight of each month, to occurring weekly on Tuesdays and Fridays throughout each month. The modifications in the Project survey design are intended to result in a higher detection of mortalities along the gen-tie.

Within the Survey Area, four transects were assigned and labeled with letters “A” through “D.” Transects were spaced 10 meters apart, with transects B and C occurring 5 meters on either side of centerline. Transects A and D were placed 10 meters from transects B and C, respectively, situating them15 meters on either side of center line in order to provide full visual ground coverage of the survey area (Figure 3).

2.2 TRANSECT SAMPLING

During transect sampling, two biologist walked transects, scanning the ground for evidence of avian mortalities such as carcasses, feather spots, scavenged carcasses, or individual feathers (sign). When sign was observed, the biologists marked their location from which the observation occurred on the transect with a pin flag, and collected and entered data on the Avian Mortality Reporting Form (Appendix A). Once all data was collected and entered, the biologists returned to their marked location and resumed transect sampling.

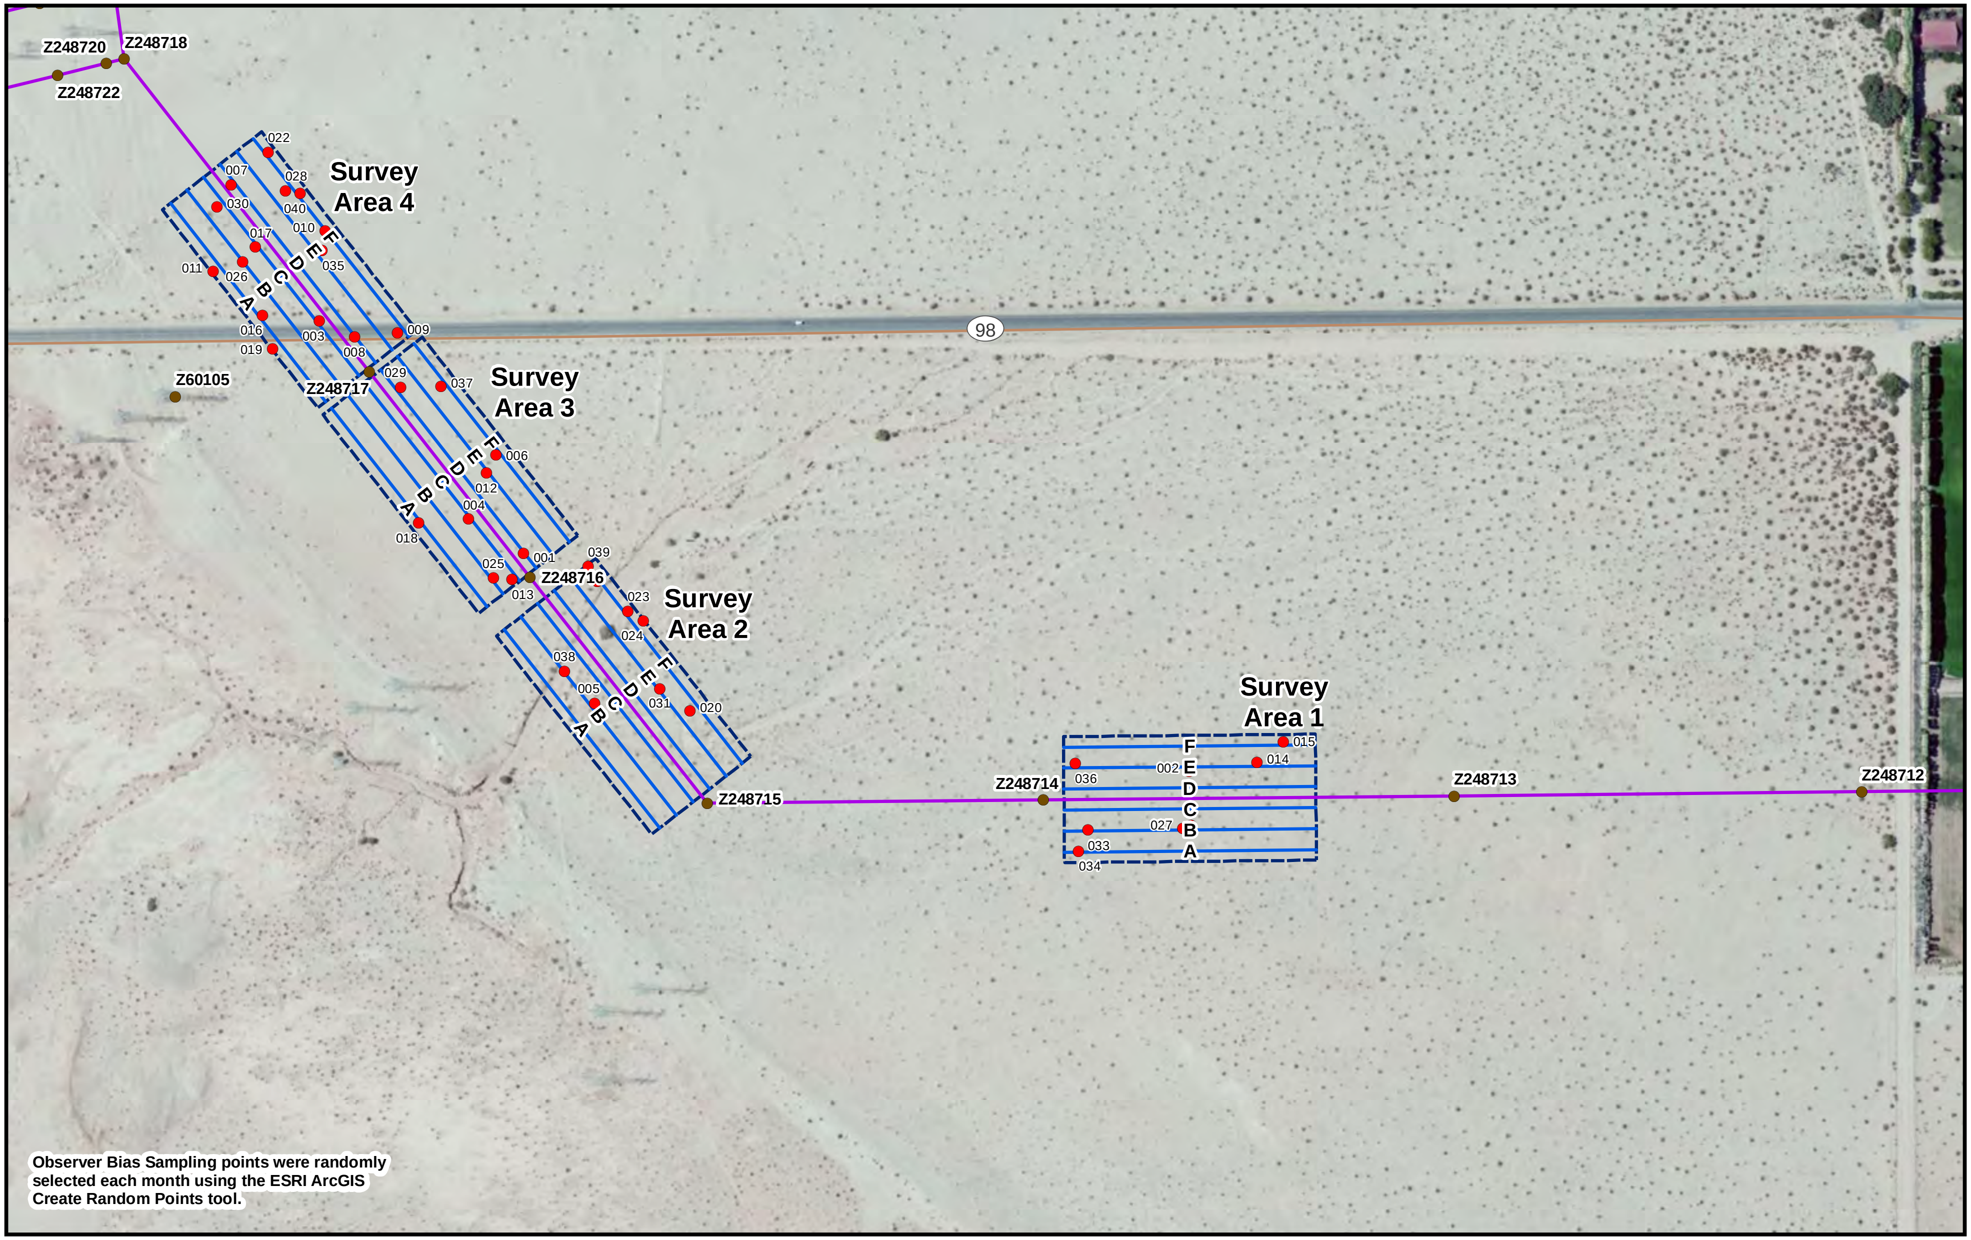
2.3 OBSERVER BIAS STUDY

The observer bias study was conducted during year one only along the original Project Survey Area design. As such, the study area included only 20 percent of the gen-tie line. The observer bias study was conducted concurrently with transect surveys during year one to eliminate any differences in variables between the surveys. Up to 40 trial birds (observer bias objects) with unique numbers were placed at random within the survey transect areas. Random placement locations within survey transect areas were selected using the “Create Random Points” tool in ArcGIS. Artificial birds with realistic feathers and coloration were used as observer bias objects. Study objects ranged from 3.5 to 5 inches in length. Coloration of study objects were brown, gray, other drab colors, and yellow, to mimic species naturally occurring within the survey area, such as migrating warblers and sparrows (Photograph 1). Locations for placement of observer bias objects were documented using Arc GIS software. A sample of randomly generated observer bias object locations is included in Figure 4. To remove bias, the biologist placing trial birds did not conduct avian line-strike surveys for the given survey period. Random selection of placement for observer bias study objects was repeated for each round of surveys.

Photograph 1.
Representative examples of observer bias objects used for study

When avian mortality surveyors located an observer bias object, information including UTM location and assigned object number was recorded to verify data collection accuracy. The object was then collected and removed from the survey area. Observer bias study data was collected during each trial period to account for varying avian abundance, seasonal variables, and environmental variables that may change over the course of the year. Additionally, conducting the observer bias study concurrently with the mortality surveying efforts ensures that the observer’s effort is consistent across studies.



Observer Bias Sampling points were randomly selected each month using the ESRI ArcGIS Create Random Points tool.

2.4 SCAVENGING BIAS STUDY

During transect sampling, all sign of avian mortality was recorded and given a unique identifier. Unique identifiers were assigned by year, month, day, and the number of avian mortalities observed during the day. For example, the second (02) potential avian mortality observed on April 14, 2015 would be labeled 20150414_02. This unique identifier was used to conduct follow-up monitoring observations for each intact carcass located during the following survey period. Following initial observation, biologists checked the status of each carcass during all subsequent surveys for use in the scavenger bias study. Observers returned to each mortality to monitor for scavenger activity until the carcass was naturally removed. Once a carcass was no longer present, biologists recorded the last day the carcass was observed. The initial and last observation dates the carcass was observed were used to determine the average number of days carcasses persisted within the survey area prior to being naturally removed.

2.5 CARCASS REMOVAL TRIAL

Two rounds of carcass removal trials were conducted over the course of five consecutive days. Carcass removal trials were conducted concurrently with BBCS mortality surveys where feasible. Carcass removal trials consisted of 10 avian carcasses (brown-headed cowbirds) randomly placed within the BBCS Survey Area at sunrise, when mortality surveying typically occurs (Figure 5). Care was taken to survey for potential scavengers during the placement of carcasses so as not to attract scavengers to the area. Following placement of the trial carcasses, biologists returned to monitor scavenging and removal of carcasses daily at sunrise. During the five day monitoring period, two of the trial carcass checks occurred during scheduled BBCS mortality surveys, for a total of three additional days for each trial period. During carcass checks, presence/absence, condition, and sign of all trial carcasses was documented. Information collected was used to determine the rate of carcass removal between BBCS mortality surveys (two day and three day intervals). This data was used to extrapolate the number of mortalities likely occurring during days when BBCS mortality surveys did not occur based on the observed number of mortalities and known observer bias/detection rates. A total of two trials were conducted; one in late spring (May) and one in summer (June). No trials were conducted during fall and winter due to expected low numbers of observed mortalities and relative decline of potential scavengers during the avian non-breeding season.

SECTION 3.0 – RESULTS

3.1 TRANSECT SAMPLING RESULTS

Sixteen intact avian carcasses were observed during transect sampling within the Survey Areas during the survey year (October 2014 – December 2015). In addition to documenting intact carcasses, data was collected when scavenged, dismembered carcasses, or injured birds were observed during transect sampling. Table 1 shows the number of carcass observations by carcass condition observed during each survey period. Table 2 summarizes the total number of mortalities observed by carcass condition for survey year two. The location of all observed carcasses is shown in Figure 6.

Table 1: Number of Carcass Observations Per Month

Carcass Condition	October 2014	November 2014	December 2014	January 2015	February 2015	March 2015	April 2015	May 2015	June 2015	July 2015	August 2015	September 2015	October 2015	November 2015	December 2015

Table 2: Summary of Carcass Observations for Year Two

Carcass Condition	Cumulative Observations
Intact	16
Scavenged	4
Dismembered	4
Injured	0
Cumulative Total	24

Intact carcasses of one Eurasian collared-dove, one common yellowthroat, one Brewer's sparrow, one MacGillivray's warbler, one orange-crowned warbler, five Wilson's warblers, one western tanager, one white-winged dove, one vesper sparrow, one unknown Epidonax species (possibly willow flycatcher), one Bewick's wren, and one house wren were observed during the October 2014 – December 2015 survey year. Details including species, condition, and location of all intact avian carcasses are included in Table 3. On average, intact avian carcasses were observed 12.60 meters from the gen-tie line centerline.

3.2 OBSERVER BIAS STUDY RESULTS

The observer bias study was conducted during year one only (October 2013 – September 2014). The year one observer bias study resulted in an average rate of detection for observer bias objects of 92.77 percent for objects present for one day within the Survey Area. The average observation bias rate represents the likelihood of a mortality being detected on the initial survey day following its occurrence within the Survey Area. Table 4 shows the number of observer bias objects placed within all the survey areas for a given survey period and the subsequent number of objects detected on the first survey day following the objects being present. In order to prevent conditioning of surveying biologists expecting observer bias objects to be placed within the first day of a survey period, placement of objects within the Survey Area occurred at different times within each survey month. The number of objects placed was also varied randomly. Finally, during two survey periods (March and September), no observer bias objects were placed. These measures were taken intentionally to avoid bias within the observer bias trial. Results from April are not included in determining average detection rate due to an extreme wind event that resulted in observer bias objects being blown outside of the survey area; therefore, these objects would not have been expected to be detected given the study's methods.

Table 4: Year One Observer Bias Study Results

Month	Number of Objects Placed	Number of Objects Detected	Percent Detection

*Represents average rate of detection between survey months not including results from April due to environmental variables.

3.3 SCAVENGING BIAS STUDY RESULTS

In total, 16 intact carcasses and 8 scavenged and dismembered carcasses were detected during the October 2014 – December 2015 survey year. Of intact carcasses detected, all carcasses were surveyed during following surveys for use for the scavenger bias study. Scavenged and dismembered carcasses detected were not used in the scavenging bias study. Carcasses were removed an average of 2.63 days after initial observation, resulting in 88 percent of all carcasses being scavenged within three days of mortality.

3.4 CARCASS REMOVAL TRIAL

A total of two carcass removal trials were conducted during year two, one in late spring (May) and one in summer (June). During the spring trial, five of the ten carcasses were scavenged within one day of placement, three additional carcasses were scavenged within two days of placement, and the remaining two carcasses remained through the end of the survey period. During the summer trial, three out of ten carcasses were scavenged within one day of placement, one was scavenged within two days, three were scavenged within three days, one was scavenged within four days, and two of the carcasses remained through the end of the survey period.

Table 6: Carcass Removal Trial Results

Trial	# of Carcasses Scavenged within One Day	# of Carcasses Scavenged within Two Days	# of Carcasses Scavenged within Three Days	# of Carcasses Scavenged within Four Days	# of Carcasses Scavenged within Five Days
Spring	5	3	0	0	0
Summer	3	1	3	1	0

SECTION 4.0 – ANALYSIS

4.1 OBSERVER BIAS ANALYSIS

The literature review results of observation bias rates are misleading because of differing environmental variables across studies (e.g., ground cover, elevation changes, bird size). A literature review of observation rates varied from 30 to 86 percent due to those variables (Morrison 2002). Although this makes comparing observer bias rates difficult, the results of the observer bias study conducted during year one showed an average observer detection rate of 92.77 percent. Our result is higher than any other reported observation rate from the literature review; however, no studies reviewed took place in such open creosote scrub habitat.

4.2 OPTIMAL TRANSECT WIDTH ANALYSIS

In total, 16 observations of intact avian carcasses were made during the survey year, October 2014 - December 2015. The sample size is too small to generate a statistically significant result for optimal transect width as required by the CSE BBCS using DISTANCE, the statistical software program identified in Section 6 Post-Construction Monitoring. Ideally, if the study were able to gather sufficient data points, the data would have been used to analyze detection probabilities given varying distances from the centerline using DISTANCE. This would have provided a range of transect width options from the centerline that produce detection probabilities of up to 100 percent. Only intact line strike detections would be used for analysis because the original location or probable cause of death for scavenged avian detections cannot be determined[1].

4.3 SCAVENGING BIAS ANALYSIS

During the October 2014 - December 2015 survey year, all 16 intact avian mortalities were selected for the scavenger bias study. Although all were subsequently scavenged, with an average of 2.63 days from detection to scavenging event, this is not a sufficient sample to statistically analyze scavenger rate.

4.4 CARCASS REMOVAL TRIAL

During the spring 2015 trial, 50 percent of carcasses were scavenged within one day and 80 percent of the carcasses had been scavenged within two days. During the summer 2015 trial, 30 percent of the carcasses were scavenged within one day and 70 percent had been scavenged within three days of placement. The removal trials show that on average 75 percent of carcasses are scavenged within three days of placement. As such, it is expected that survey results for the October 2014 - December 2015 survey period spaced an average of 2.5 days apart (48 to 72 hours) likely resulted in an approximate detection rate of 25 percent of the total avian mortalities occurring within the Survey Area due to scavenger removal.

---

[1] Because scavenged carcasses have been disturbed, moved, or otherwise altered from their origin, carcasses initially observed in the scavenged condition were not included in the project data set for these studies due to their potential of presenting a confounding variable at this stage of the study. Although data was collected for scavenged, dismembered, and injured birds, Avian Mortality Reporting Forms were not submitted because these observations are not necessarily indicative of line strikes within the Study Area.

SECTION 5.0 – DISCUSSION

5.1 STUDY AREA SELECTION

Conducting post-construction avian mortality surveys, observer bias studies, scavenger bias studies, and carcass removal trials within both the creosote scrub habitat located along the western portion of the gen-tie line and within the private agricultural land located along the eastern portion of the gen-tie line presented the following potential complications with survey design and data analysis.

5.1.1 Vegetation Substrate

Vegetation height within an agricultural area can be highly variable within a year, season, or month. As a result, detection probability by observers would also be expected to vary between each month of surveys depending on crop maturity, density, and species. If crop height and/or density is high, then detection probability would be expected to decrease, resulting in a smaller sample size of data. Additionally, crop height and/or density may also result in a higher scavenging bias being perceived. For example, surveyors may find only easily located carcasses, which would also be easily located by scavengers; therefore, when carcasses are marked for capture/recapture analysis, an inaccurate scavenging bias could be determined. Lastly, variable vegetation within a year would require that observer bias be accounted for each crop stage or type and then applied separately to each survey period, rather than a uniform observer bias determined over the course of a year being applied to the CSE BBCS Project as a whole.

5.1.2 Survey Replication

Replication of each survey transect for the duration of the survey period is a critical component in applying the software program DISTANCE. By placing survey transects within the private agricultural section of the gen-tie line, the study would have run the risk of not being able to replicate transects each month. One potential complication is denial of land access during a survey day or entire survey period. Land access may be denied due to crop harvesting, damage being done to crops during the study, unsafe conditions such as flooding, or by owner preference. Similarly, if equipment is operating within a survey transect, conditions may not be safe for access by the surveyor within the appropriate survey window. The potential inability to replicate surveys throughout the study duration would be a significant project design flaw.

5.1.3 Human Disturbance

Agricultural areas are subject to various types of disturbance throughout the year. Should harvesting, tilling, or other land alteration occur within transects, carcasses may be disrupted, buried, destroyed, or removed. If any of the aforementioned activities did occur, potential would exist that a significant percentage of mortalities could become detectable (that previously may have gone undetected) or go undetected, skewing the data. If any of these activities were to occur following the initial day of surveys within a survey period, removal of carcasses by anthropogenic means could artificially inflate scavenging bias due to marked birds no longer being present or detectable. These potential disturbances could also result in surveys not being accurately replicated, as described above.

5.1.4 Variations in Avian Abundance Between Habitats

By surveying two different habitats, the study may observe variations in avian abundance within the Study Area. If the agricultural areas have seed storage or harvesting or provide additional sources of food/water, avian numbers may be higher in these areas. Conversely, human activity and lighting may deter birds from the area. Although statistical models are capable of extrapolating mortalities for the CSE BBCS Project area within multiple habitat types, reliability of estimates increases when surveys include areas with monotypic habitat, an expected high detection probability, and consistent abundance of birds throughout the survey area.

5.1.5 Modification to Avoid Design Flaws

Many of the design flaws described above were avoided by having the Study Area include only creosote scrub habitat along the western portion of the CSE BBCS Project. Survey transects accounted for 50 percent of the entire 2.5-mile gen-tie line; however, by not surveying the portion of the gen-tie line on agricultural land, extrapolating avian mortalities over the Project timeline did not account for any potential differences in the abundance/frequency of potential line strikes occurring between the creosote scrub habitat and the agricultural areas. Analysis was intended to be performed using Program DISTANCE to extrapolate the total number of mortalities recorded only within the native creosote scrub habitat. This number would then be applied to the remainder of the line (the agricultural area) as a function of the linear distance. For example, the creosote scrub habitat to be surveyed would account for 50 percent of the entire gen-tie. Thus the agricultural area of the line would represent 2 times the linear distance of the gen-tie as that represented by the creosote scrub area. Avian mortalities extrapolated within the creosote scrub habitat using DISTANCE would be multiplied by 2. This method did not account for any differences in the number of potential line strikes occurring between different habitat types. Therefore, the assumption can be made that if the mortalities are higher within creosote scrub than agricultural land, the total extrapolated number of mortalities for the entire gen-tie line will be overestimated. Conversely, if mortalities are higher within agricultural areas than creosote scrub, the total extrapolated number of mortalities for the entire gen-tie line will be underestimated.

While over or underestimating numbers of mortalities are potential problems, from the perspective of feasibility, surveying only within creosote scrub habitat remained the preferred CSE BBCS Project design. The reduced Study Area did not account for habitat variations along the gen-tie line, but it did allow for a usable set of data to be collected for the study and greatly reduce the possibility of being unable to collect statistically sound and accurate data, replicate surveys, or having to mitigate for unknown variables.

5.2 SCAVENGING BIAS

Although only 16 intact avian carcasses were observed and included in the scavenging bias trial, there is reason to suspect that common ravens and coyotes are primarily responsible for scavenging mortalities. Photograph 2 provides evidence of this from a shot captured by a Cuddeback camera that was placed during the year one survey facing an avian mortality (ID 5_4_03, a Wilson's warbler). This avian mortality was a probable line strike that likely occurred the morning it was found. The condition of the warbler's body at the time of initial observation suggested that the carcass was found within a few hours of its death. The camera was placed at approximately 0835 on May 4, 2014. The camera was triggered by the raven and took Photograph 2 at 0954 on May 4, 2014, suggesting that common ravens can potentially scavenge avian mortalities within a few hours of their death. In addition, during surveys and the carcass removal trials conducted during year two, ravens were directly observed picking up carcasses several times, and coyote tracks and large clumps of feathers were observed leading to areas where two carcasses had been placed. Coyote tracks were regularly observed throughout surveys during year one and two, as shown in Photograph 3.

Although coyotes primarily scavenge and hunt at night, biologists reported seeing coyotes in transects as late as 0900 during surveys. It is probable that coyotes are capable of scavenging avian mortalities the same day as death.

Photograph 2.

Common raven photographed immediately prior to scavenging avian mortality ID 5_4_03

Photograph 3.

Coyote tracks found adjacent to a scavenged carcass

5.2.1 Observations of Scavenged Mortalities

During the year two reporting period, a total of four mortalities were observed in the scavenged condition. Scavenged carcasses present a unique dataset for this study in that they represent a mortality disturbed from its original location and condition. Although data was collected on Avian Mortality Report forms for all scavenged carcasses, these observations pose several potential complications during analysis. Scavenged carcasses may represent natural predation events, and mortalities may not be attributed to collisions. Thus, inclusion of these observations may result in over estimation of total avian mortalities within the study. Furthermore, during the scavenging event, carcasses may be transported or moved within a survey area, resulting in modification of the carcasses distance from the centerline and therefore should not be used to evaluate optimal transect width. Only if sufficient data is available regarding the consistency of scavenged carcasses with intact carcasses in relationship to distance from centerline, species represented, detection probability, and potential translocation during scavenging, should these points be reliably included in the dataset.

5.3 SEASONAL VARIATION

As discussed by Bevanger & Brøseth (2004) and Smallwood (2007), avian line-strike rates with electrical power lines vary by season due to fluctuations of seasonal abundance. Given that the CSE BBCS Project area is located within a critical area of the Pacific Flyway, bird abundance was anticipated to be greatest during spring and fall migrations. As expected, it appeared that spring migration saw an increase in avian mortality detections as well as an increase scavenger activity, particularly during the May surveys. However, there was not a spike in mortality or bird activity during the fall migration as previously anticipated. Common ravens were present and actively scavenging during the spring and early summer months of the spring migration, but by late June common ravens were less frequently observed within the Study Area. However, sample sizes for this Project are small, and do not provide statistically significant findings to support nor refute the correlation of seasonal migrations by passerines with numbers of line strikes.

5.4 CSE BBCS PROJECT DESIGN MODIFICATION

A total of nine mortalities were observed during the year one survey period. In order to increase the number of mortalities detected, the Project survey design was modified and extended to include three additional months during year two. The modified survey design during year two resulted in the detection of 24 mortalities. Although more mortalities were observed during year two, the number of observed mortalities did not provide a sufficient amount of data to run statistically sound analyses of an optimal transect width for the CSE BBCS Project, to extrapolate total avian mortality on the CSE BBCS Project by survey year, or to estimate scavenger and observation bias rates using the program DISTANCE.

5.5 ESTIMATED TOTAL AVIAN MORTALITY

The survey design implemented during year two of the Project did not provide a sample size large enough to run statistical analysis to obtain an estimate of total avian mortality. However, with the information gathered from the observer bias study and the scavenger studies, a general estimate of avian mortalities can be obtained. It should be noted that this estimated number represents a maximum expected number of mortalities and does not account for seasonal variation, changes in scavenger abundance, variations in survey spacing (two days versus three days) or other confounding factors. The following assumptions are made for the entire line:

1. Avian mortality rates are consistent throughout the entire gen-tie
2. Scavenger bias rates for carcass removal are estimated at the maximum rate of 82 percent within a three day period and are consistent throughout the survey period (i.e. 18 percent of mortalities would be detected for surveys spaced 3 days apart)
3. The carcass detection rate for the entire gen-tie is 93 percent of all mortalities occurring

The assumptions above were applied to a total of 24 avian mortalities observed within the Survey Area (including all intact, scavenged, and dismembered). Based on the Survey Area including 50 percent of the total gen-tie, a total of 48 mortalities were estimated for detection of the entire 2.5 mile gen-tie. When taking into account the results of the observer bias studies and the percent of carcasses scavenged within three days, it can be estimated that on average 286 (48 divided by 0.18 (number of mortalities detected every three days) divided by 0.93 (rate of detection)) avian mortalities occur yearly along the CSE BBCS Project, with the majority of these mortalities occurring during the spring migration.

APPENDIX A – AVIAN MORTALITY REPORTING FORM

CENTINELA SOLAR ENERGY PROJECT MORTALITY REPORTING FORM

DATE: 03/17/2015 **TIME: 7:47 AM** **OBSERVER: showard**

PROXIMAL TO PROJECT COMPONENT: Z248718

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 621285 North: 3616674

BEARING (degrees) to PROJECT COMPONENT: 147

DISTANCE (meters) to PROJECT COMPONENT: 52

CARCASS DESCRIPTION

SPECIES: ECDO Tag/Band Number: None

AGE: Adult SEX: Female CONDITION: Intact

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): <1 day

CAUSE OF DEATH: Presumed Collision

OBSERVABLE INJURIES: Head Trauma

SUBSTRATE/GROUND COVER *(at carcass location):* Bare Ground

DISPOSITION OF CARCASS[1]: left in place

NOTES: Brood patch, early in development likely not yet incubating. Carcass initially observed on 3/17 and naturally observed to be removed by scavengers on 3/20 (next survey pass). Scattered feather spot observed within 20ft of location.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit): 68-76 CLOUD COVER: none

PRECIPITATION (last 24 hours): partly cloudy WIND DIRECTION: North WIND SPEED: 0-10

PHOTOGRAPHS:

	**Photograph 1.** Eurasian collared dove 20150317_01
	**Photograph 2.** Eurasian collared-dove 20150317_01
	**Photograph 3.** Habitat surrounding Eurasian collared-dove 20150317_01
	**Photograph 4.** Nearest project feature to Eurasian collared-dove 20150317_01

CENTINELA SOLAR ENERGY PROJECT MORTALITY REPORTING FORM

DATE:03/24/2015 **TIME: 8:15 AM** **OBSERVER: showard**

PROXIMAL TO PROJECT COMPONENT: Z248714

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 622076 North: 3616106

BEARING (degrees) to PROJECT COMPONENT: 176

DISTANCE (meters) to PROJECT COMPONENT: 105

CARCASS DESCRIPTION

SPECIES: BRSP Tag/Band Number: None

AGE: Adult SEX: Female CONDITION: Intact

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): <1 day

CAUSE OF DEATH: Presumed Collision

OBSERVABLE INJURIES: Head Trauma

SUBSTRATE/GROUND COVER *(at carcass location):* Bare Ground

DISPOSITION OF CARCASS[1]: left in place

NOTES: Intact carcass appears to have broken neck. No other observables injuries.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit): 61- 77 CLOUD COVER: none

PRECIPITATION (last 24 hours): partly cloudy WIND DIRECTION: South WIND SPEED: 0-10

PHOTOGRAPHS:

Photograph 1. Brewer's sparrow 20150324_01

Photograph 2. Brewer's sparrow 20150324_01

CENTINELA SOLAR ENERGY PROJECT MORTALITY REPORTING FORM

DATE: 03/27/2015 **TIME: 8:29 AM** **OBSERVER: showard**

PROXIMAL TO PROJECT COMPONENT: Z248720

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 621229 North: 3616668

BEARING (degrees) to PROJECT COMPONENT: 94 DISTANCE (meters) to PROJECT COMPONENT: 30

CARCASS DESCRIPTION

SPECIES: COYE ID: 03_27_01 Tag/Band Number: None

AGE: Adult SEX: Male CONDITION: Intact

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): <1 day

CAUSE OF DEATH: Unknown

OBSERVABLE INJURIES: None

SUBSTRATE/GROUND COVER *(at carcass location):* Bare Ground

DISPOSITION OF CARCASS[1]: left in place

NOTES: Probable line strike mortality.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit): 61-86 CLOUD COVER: none

PRECIPITATION (last 24 hours): clear WIND DIRECTION: Northeast WIND SPEED: 0-10

PHOTOGRAPHS:

	**Photograph 1.** Common yellowthroat 20150327_01
	**Photograph 2.** Common yellowthroat 20150327_01
	**Photograph 3.** Habitat surrounding common yellowthroat 20150327_01
	**Photograph 4.** Habitat surrounding and nearest project feature surrounding common yellowthroat 20150327_01

CENTINELA SOLAR ENERGY PROJECT MORTALITY REPORTING FORM

DATE: 04/13/2015 **TIME: 6:47 AM** **OBSERVER: showard**

PROXIMAL TO PROJECT COMPONENT: Z248714

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 622061 North: 3616115

BEARING (degrees) to PROJECT COMPONENT: -179

DISTANCE (meters) to PROJECT COMPONENT: 90

CARCASS DESCRIPTION

SPECIES: Warbler Tag/Band Number: none

AGE: Unknown SEX: Unknown CONDITION: Scavenged

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): 2 days

CAUSE OF DEATH: Unknown

OBSERVABLE INJURIES: Other

SUBSTRATE/GROUND COVER *(at carcass location):* Bare Ground

DISPOSITION OF CARCASS[1]: left in place

NOTES: Partial left wing of unknown warbler species with connective tissue present. Kit fox prints in immediate area surrounding.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit): 63-65 CLOUD COVER: none

PRECIPITATION (last 24 hours): clear WIND DIRECTION: Northeast WIND SPEED: 0-10

PHOTOGRAPHS:

	**Photograph 1.** Unknown warbler 20150413_01
	**Photograph 2.** Unknown warbler 20150413_01
	**Photograph 3.** Habitat surrounding unknown warbler 20150413_01
	**Photograph 4.** Nearest project feature to unknown warbler 20150413_01

CENTINELA SOLAR ENERGY PROJECT MORTALITY REPORTING FORM

DATE: 04/17/2015 **TIME: 7:05 AM** **OBSERVER: showard**

PROXIMAL TO PROJECT COMPONENT: Z248717

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 621432 North: 3616446

BEARING (degrees) to PROJECT COMPONENT: 63

DISTANCE (meters) to PROJECT COMPONENT: 8

CARCASS DESCRIPTION

SPECIES: OCWA ID: 20150417_01 Tag/Band Number: None

AGE: Adult SEX: Female

CONDITION: Intact

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): <1 day

CAUSE OF DEATH: Presumed Collision

OBSERVABLE INJURIES: Head Trauma

SUBSTRATE/GROUND COVER *(at carcass location):* Bare Ground

DISPOSITION OF CARCASS[1]: left in place NOTES: Female OCWA directly under conductor, left side of face sheered off and exposed from presumed collision. 4/21/15 Carcass observed through binoculars to be present in same location. CORA picked up carcass after monitors resumed survey –kquint.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit):60-80 CLOUD COVER: none

PRECIPITATION (last 24 hours): clear WIND DIRECTION: South WIND SPEED: 0-10

PHOTOGRAPHS :

	**Photograph 1.** Orange-crowned warbler 20150417_01
	**Photograph 2.** Orange-crowned warbler 20150417_01
	**Photograph 3.** Habitat surrounding orange-crowned warbler 20150417_01
	**Photograph 4.** Nearest project feature to orange-crowned warbler 20150417_01

CENTINELA SOLAR ENERGY PROJECT MORTALITY REPORTING FORM

DATE: 04/21/2015 **TIME: 6:39 AM** **OBSERVER: kquint**

PROXIMAL TO PROJECT COMPONENT: Z248715

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 621765 North: 3616128

BEARING (degrees) to PROJECT COMPONENT: -164

DISTANCE (meters) to PROJECT COMPONENT: 63

CARCASS DESCRIPTION

SPECIES: MGWA ID: 20150421_01 Tag/Band Number: None

AGE: Adult SEX: Male CONDITION: Intact

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): <1 day

CAUSE OF DEATH: Presumed Collision

OBSERVABLE INJURIES: Head Trauma

SUBSTRATE/GROUND COVER *(at carcass location):* Bare Ground

DISPOSITION OF CARCASS[1]: left in place

NOTES: 4/24/15 Carcass absent. Likely CORA tracks present where carcass initially observed.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit): 64-73 CLOUD COVER: none

PRECIPITATION (last 24 hours): mostly clear WIND DIRECTION: Northwest WIND SPEED: 0-10

PHOTOGRAPHS:

	**Photograph 1.** MacGillivray's warbler 20150421_01
	**Photograph 2.** MacGillivray's warbler 20150421_01
	**Photograph 3.** Habitat surrounding MacGillivray's warbler 20150421_01
	**Photograph 4.** Nearest project feature to MacGillivray's warbler 20150421_01

CENTINELA SOLAR ENERGY PROJECT MORTALITY REPORTING FORM

DATE: 04/28/2015 **TIME: 11:34 AM** **OBSERVER: rhutcheson**

PROXIMAL TO PROJECT COMPONENT: Z248719

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 621245 North:3616773

BEARING (degrees) to PROJECT COMPONENT: -134

DISTANCE (meters) to PROJECT COMPONENT: 17

CARCASS DESCRIPTION

SPECIES: WIWA ID: 201504281_01 Tag/Band Number: None

AGE: Adult SEX: Male CONDITION: Intact

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): 2 days

CAUSE OF DEATH: Presumed Collision

OBSERVABLE INJURIES: Head Trauma

SUBSTRATE/GROUND COVER *(at carcass location):* Below Ankle

DISPOSITION OF CARCASS[1]: left in place

NOTES: Carcass estimated to be present for greater than one day based on desiccated eyes and ants present on carcass.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit): 67-72 CLOUD COVER: none

PRECIPITATION (last 24 hours): clear WIND DIRECTION: West WIND SPEED: 0-10 .

PHOTOGRAPHS:

	**Photograph 1.** Wilson's warbler 20150428_01
	**Photograph 2.** Wilson's warbler 20150428_01
	**Photograph 3.** Habitat surrounding Wilson's warbler 20150428_01
	**Photograph 4.** Nearest project feature to Wilson's warbler 20150428_01

CENTINELA SOLAR ENERGY PROJECT MORTALITY REPORTING FORM

DATE: 05/05/2015 **TIME: 5:22 AM** **OBSERVER: kquint**

PROXIMAL TO PROJECT COMPONENT: Z248712

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 622535 North: 3616133

BEARING (degrees) to PROJECT COMPONENT: -8

DISTANCE (meters) to PROJECT COMPONENT: 86

CARCASS DESCRIPTION

SPECIES: WIWA ID: 20150505_01 Tag/Band Number: None

AGE: Adult SEX: Male CONDITION: Intact

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): <1 day

CAUSE OF DEATH: Unknown

OBSERVABLE INJURIES: None

SUBSTRATE/GROUND COVER *(at carcass location):* Bare Ground

DISPOSITION OF CARCASS[1]: left in place

NOTES: Carcass appears stiff with rigormortis set in. Unable to determine COD, potential neck trauma.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit): 67-80 CLOUD COVER: none

PRECIPITATION (last 24 hours): clear WIND DIRECTION: Northeast WIND SPEED: 0-10

PHOTOGRAPHS:

Due to technical difficulties, no photographs are available

CENTINELA SOLAR ENERGY PROJECT MORTALITY REPORTING FORM

DATE: 05/08/2015 **TIME: 7:07 AM** **OBSERVER: rhutcheson**

PROXIMAL TO PROJECT COMPONENT: Z248723

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 621122 North 3616748

BEARING (degrees) to PROJECT COMPONENT: -111

DISTANCE (meters) to PROJECT COMPONENT: 17

CARCASS DESCRIPTION

SPECIES: WIWA ID: 20150508_01 Tag/Band Number: None

AGE: Adult SEX: Female CONDITION: Intact

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): 2 days

CAUSE OF DEATH: Unknown

OBSERVABLE INJURIES: None

SUBSTRATE/GROUND COVER *(at carcass location):* Bare Ground

DISPOSITION OF CARCASS[1]: left in place

NOTES: Carcass appears stiff with rigamortis. Estimated time since death approximately 2 days. Likely result of recent storm event.

Carcass found adjacent to 230kv line and may not be associated with Project.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit): 57-62 CLOUD COVER: none

PRECIPITATION (last 24 hours): mostly clear WIND DIRECTION: Northwest WIND SPEED: 0-10

PHOTOGRAPHS:

PROXIMAL TO PROJECT COMPONENT: Z248715

CARCASS POSITION

GPS COORDINATES (UTM NAD83) 11S East: 621763 North: 3616140

BEARING (degrees) to PROJECT COMPONENT: -154

DISTANCE (meters) to PROJECT COMPONENT: 65

CARCASS DESCRIPTION

SPECIES: Unknown warbler ID: 20150512_01 Tag/Band Number: None

AGE: Unknown SEX: Unknown CONDITION: Dismembered

ESTIMATED TIME SINCE DEATH/INJURY (no. of days): 2 days

CAUSE OF DEATH: Unknown

OBSERVABLE INJURIES: Other

SUBSTRATE/GROUND COVER *(at carcass location):* Bare Ground

DISPOSITION OF CARCASS[1]: left in place

NOTES: Single left wing actively being scavenged by ants. Likely that remainder of carcass was removed from survey area. Wing is warbler or similar size and drab gray with nearby flight feather displaying white patch.

WEATHER CONDITIONS

AIR TEMPERATURE (degrees fahrenheit): 70-90 CLOUD COVER: none

PRECIPITATION (last 24 hours): mostly cloudy WIND DIRECTION: North WIND SPEED: 0-10

Enclosed is the requested carcass, Bank Swallow (*Riparia riparia)*. This bird is incident 2015_422_ISEGS, according to naming convention used for all on-site fatalities. UTMs and details are provided on the enclosed card (with the carcass). The bird has been processed, documented, and archived as required by our SPUT guidelines on site (ISEGS).

As Field Lead for the WEST-Inc Avian/Bat Team, I collected, processed, and shipped this bird personally. Detailed documentation (including age/sex, carcass notes, discovery notes) are documented on site, and available if required.

Please contact Doug Davis, site representative, or myself for further information.

Copies of our SPUT and SCP permits are attached.

2014 Second Quarterly Report

COA 62 Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan Quarterly Report

July 10, 2014

Discussion

The enclosed report has been prepared to address the reporting requirements for Condition of Approval (COA) 62 Bird Monitoring and Avoidance Plan (BMAP). This plan is merged with the Avian and Bat Protection Plan (ABPP), comprising a comprehensive avian management plan for the Topaz project.

In response to COA 62, the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP/BMAP) has been prepared, which further describes the approach to implementing the condition requirements.

COA 62 requires quarterly and annual reports. Quarterly reports are required during construction and for three years following the beginning of plant operation.

Following the completion of the fourth quarter of monitoring the biologist shall prepare an annual report that summarizes the year's data, analyzes any project-related bird fatalities or injuries detected, and provides recommendations (in consultation with the County) for future monitoring and any adaptive management actions needed.

Quarterly Reportable Items

COA 62 BMAP requires quarterly reports describing the dates, durations, and results of monitoring and data collection. The quarterly reports shall provide a detailed description of any project-related bird or wildlife deaths or injuries detected during the monitoring study or at any other time.

Report Data

Attached is the quarterly report prepared by Althouse & Meade (COA 62 and ABPP Quarterly Monitoring Report by Althouse & Meade April 01- June 30, 2014.

1.0 Introduction

This Year 3 Second Quarter report provides bird and bat information as specified in the Topaz Solar Farms Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP and BMAP; Althouse and Meade, Inc. June 2011). Section 5.5 of the ABPP and BMAP describes information to be included in reports and requires quarterly reports to be submitted to the County of San Luis Obispo (County), U.S. Fish and Wildlife Service (USFW) and the California Department of Fish and Wildlife (CDFW). The Avian and Bat Protection Plan (ABPP; Section 2.0) and Bird Monitoring and Avoidance Plan (BMAP; Section 3.0) are requirements of County of San Luis Obispo Conditions of Approval (COA) 61 and 62, and were prepared in consultation with USFWS and CDFW.

1.1 Construction Status

Construction of Blocks 1-9 was completed in 2013, and Blocks 10-17 were completed in 2014 by the end of June (Table 1). All completed blocks were transferred to and are now managed by Operations and Maintenance (O&M). Exhibit 1 illustrates construction status of Blocks through June 2014.

TABLE 1. CONSTRUCTION STATUS BY BLOCK. Date of transfer to O&M is provided for Blocks 1-17. Bold indicates transfer during 2nd quarter.

Block(s)	Month and Year Transferred to O&M	Block(s)	Month and Year Transferred to O&M
1	March 2013	**12**	**May 2014**
2	March 2013	**13**	**May 2014**
3	March 2013	14	January 2014

2.0 Avian and Bat Protection Plan

The ABPP monitoring program compiles general information on bird and bat presence, interactions with facility components, injuries, and mortality at the Topaz Solar Farms (TSF). During construction phases of the project this task is completed by the project biologists, as part of routine daily biological monitoring. In blocks under Operations and Maintenance (O&M) control, data is collected from a variety of sources, including pre-activity surveys, O&M technician reports, and during field work conducted for BMAP studies. Information regarding the detailed bird use and mortality risk assessment study is reported in Section 3.0.

For the ABPP, this quarterly report provides information collected during active construction in Blocks 11-13 and 16-22, spanning the period from April 1 through June 30, 2014

2.1 General Bird Surveys

2.1.1 Methods

General bird surveys are conducted on and around active construction areas of TSF project site on a daily basis seven days a week throughout the year by project biologists. Lists of bird species observed by each biological monitor are recorded on daily construction monitoring forms, which are then scanned, archived, and reviewed by project ornithologists Peter Gaede and Jason Dart.

2.1.2 Results

Monitors recorded a total of 82 species of birds in April, May, and June 2014 and an additional five birds not identified to species. Of those 82 species, 8 were waterbirds and 8 were raptors. Some of the 8 waterbird species were observed in lands surrounding Topaz including a private pond less than a thousand feet from TSF, and others were observed flying over TSF without using project features as habitat. Demolition of the TSF dust control pond (DCP) occurred during this reporting period; the DCP was where most onsite waterbird detections were recorded. Table 1 lists all bird species observed in this quarter with information on observation frequency.

TABLE 2. APRIL – JUNE 2014 GENERAL BIRD SURVEY RESULTS. All bird species recorded this quarter are listed. Top twenty species most frequently observed, waterbirds, and raptors are indicated.

Wilson's Warbler			
Yellow Warbler			
Yellow-Headed Blackbird			
Yellow-Rumped Warbler			

2.2 Nesting Activity

2.2.1 Methods

Focused nest surveys were conducted daily on and around the TSF project components under construction by biological monitors starting February 1, 2014. All nest surveys were conducted on foot by trained biologists. Strategically selected array areas near active construction were identified at the beginning of each week where surveyors walked all array rows searching for nests on the ground or on structures. Additionally, an area 300 feet around all perimeter fences of active construction areas was surveyed twice per week, per the approved Nesting Bird Management Plan (Althouse and Meade, Inc. 2013). Laydowns and move-on areas were surveyed as often as possible to prevent birds establishing nests in equipment and materials. Nests were also found by construction personnel in their work areas or incidentally found by biologists while monitoring construction activities. Nest starts were removed when the presence of a complete nest would conflict with construction activities or would present a danger to the birds. All nests and nest starts were documented. Nests identified from April to June 2014 in active construction areas are included in this report.

2.2.2 Results

The results of surveys from April through June 2014 are provided in Table 3. Other species identified nesting offsite (e.g. mitigation lands, future project lands, or areas managed by Operations and Maintenance) are not included in this table. Six horned lark nest starts were removed from construction areas during this quarter, as well as seven western kingbird and eleven house finch nest starts from equipment and materials. Many of these nest starts were multiple attempts by the same pair of birds, particularly the kingbirds. All nest starts were removed prior to being deemed complete by the Project Ornithologist. A nest was deemed complete when it was lined and ready to accept eggs. Common ravens and one pair of red-tailed hawks built nests on the PG&E transmission line power poles near the project, and ravens nested on several of the onsite medium voltage collector line poles.

A total of 71 horned lark nests were active in and near the construction areas of TSF during the second quarter of 2014 (Table 3 and Exhibit 2). Sixteen (23%) of the 71 nests fledged or were presumed to fledge successfully. Fifty-one (72%) of the nests failed. Three categories are distinguished for causes of nest failure: known/probable predation (39 nests, 55%), unknown (7 nests, 10%), and abandoned (5 nests, 7 %). Status of nest fledging could not be confidently determined for four (6%) of the 71 horned lark nests.

Eleven house finch nests were documented during the reporting period, eight (67%) of which fledged successfully. The remaining four (33%) nests failed due to several factors, as out lined in Table 3.

Of the five common raven nests, four (80%) fledged successfully and one (20%) failed due to unknown causes.

Only one mourning dove nest was located during the reporting period; it failed likely due to predation.

A red-tailed hawk nest on PGE transmission towers north of Block 11 was monitored during this reporting period; nestlings successfully fledged.

Exhibit 2 in Section 5.0 is a map of bird nests in and near areas of active construction April through June 2014.

TABLE 3. APRIL – JUNE 2014 BIRD NESTS. Active bird nests detected at Topaz Solar Farms from April to June 2014 in active construction areas.

Species	**Final Status**	**Number of Nests**	**Percent of Total**
Horned Lark	Fledged- Known/Probable	16	23
	Failed- Known/Probable Predation	39	55
	Failed- Unknown	7	10
	Failed- Abandoned	5	7
	Unknown	4	6

	Total Unknown	**4**	**4**

---

[1] One house finch nest was abandoned due to the nest being transported on material approximately a mile across the site. The nest was returned to the location where it was found but the parents did not return. The five nestlings perished despite being taken to Pacific Wildlife Care the next day.

[2] One common raven nest was considered a success, although when the single nestling attempted to fledge, its foot became entangled in nesting material and it perished.

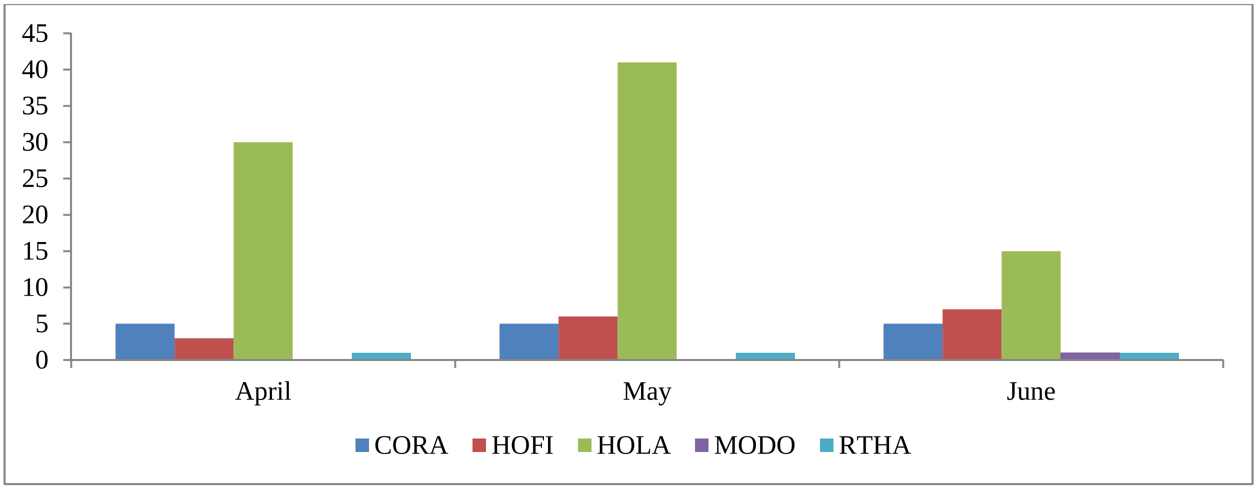

FIGURE 1. COUNT OF ACTIVE BIRD NESTS BY SPECIES AND MONTH. Bird nests detected at Topaz Solar Farms from April to June 2014 by species and month. Species abbreviations are as follows: CORA Common Raven, HOFI House Finch, HOLA Horned Lark, MODO Mourning Dove, RTHA Red-Tailed Hawk. Some nests, such as the ravens and hawks, were active during multiple months.

2.3 Avian and Other Wildlife Mortality

General biological monitoring of the Topaz work area documented bird, bat, and other wildlife mortality. All mortality identified on site during this reporting period is provided in Table 4. Cause of death is reported when known. Several of the avian fatalities identified were feather spots so predation as a cause of death could not be confirmed. Additionally, none of the collisions documented were with solar panels; the horned larks chased each other while exhibiting breeding behavior and collided with posts or windows. Snakes crossing roads or sunning themselves would often be run over by traffic throughout active construction areas. This table includes all fatalities found in active construction areas as well as areas managed by Commissioning or Operations and Maintenance.

TABLE 4. APRIL – JUNE 2014 AVIAN AND OTHER WILDLIFE MORTALITY. Bird and other wildlife mortality detected at the Topaz Solar Farms from April to June 2014. Asterisk indicates it was found during formal fatality surveys.

Month	Species	Location	Cause of Death

2.4 Adaptive Management

No adaptive management practices were implemented during the period from April through June 2014.

2.5 Bat Surveys

2.5.1 Methods

Acoustic monitoring surveys for bats on the project site were conducted at least one night per month using a Pettersson D240x (Pettersson Elektronik, Sweden) bat detector and Sonobat® (v.3.1 US west; DNDesign, Arcata, CA) acoustic analysis software. Sound frequencies between 10 and 120 kHz, the range utilized by bats, were detected and synthesized into time-expanded sound files and analyzed by Sonobat® software. Surveys were initiated near dusk, when bats commonly begin nightly foraging activities. Monitoring periods for each survey were limited to the battery-life of the Pettersson detector and typically ranged from three to six hours depending on the number of sound files detected. On April 23, 2014, the detector was placed on an extendable pole on a t-post between the Topaz Solar Farms substation and the PG&E switching station. On May 30, the detector was placed on a perimeter fencepost in the southwest corner of Block 19. On June 13, the detector was placed on a barb-wire fence post on the western edge of the Stewardship land west of Block 22, bordering the neighboring olive orchard. On June 20, the detector was placed in the northwestern corner of the Phase 6 Block 20 laydown yard. All detected bat calls were identified using the analysis software.

2.5.2 Results

On June 13, 2014 canyon bats (*Parastrellus hesperus*) were detected in the vicinity of Topaz Solar Farms; two detections consisting of 6 and 8 calls each were recorded. On June 20, 2014 two canyon bat detections of 7 and 8 calls and six Mexican free-tailed bat detections of 3 or 4 calls each were recorded within the work area of Topaz Solar Farms.

Canyon bats, formerly called western pipistrelles, are one of the smallest bats in California. They are typically considered a desert species and primarily roost in canyon and cliff sides, but may also roost in caves, mines, or buildings. Canyon bats tend to roost singly or in very small groups. They are among the most diurnal of bats and often begin foraging before sunset and continue until well after dusk. Canyon bats are considered common throughout their range. In the Carrizo Plain area, they likely roost in rocky outcroppings, cliff faces, as well as old structures.

Mexican free-tailed bats primarily roost in caves, but are frequently found in cavities under bridges and in buildings, where they roost gregariously. They may also roost singly or in small groups in large tree cavities. This species is common throughout the County. Maternity colonies form in spring and pups are born in the summer. Mexican free-tailed bats are one of the most widely distributed mammalian species in the Western Hemisphere and may fly more than 50 km a night to reach foraging areas. In the Carrizo Plain area, old barns and outbuildings likely provide abundant roosting sites for Mexican free-tailed bats.

The results of the April and May surveys showed no bat detections; however, sound files from the survey suggest the presence of acoustic interference with the detector. Table 5 provides a list of the number of detections of each bat species detected from April through June 2014. Each detection was assigned to species with a discrimination probability of 0.95 or higher.

No bat roosts are known to be present within or near the Topaz project site.

TABLE 5. TOPAZ SOLAR FARMS APRIL TO JUNE 2014 BAT SURVEYS. Bat acoustic monitoring survey dates, bat species detected at the Topaz Solar Farms project, and number of detections. Special status designations from CDFW and Western Bat Working Group (WBWG) are provided.

3.0 Bird Monitoring and Avoidance Plan

The BMAP study analyzes avian use surveys and avian fatality surveys to produce a risk index for various project components deemed to be potentially dangerous to birds, including array areas, overhead power lines and the Substation. Offsite grassland reference sites are used to gauge background mortality levels. Results are reported in this second quarterly report for Avian Use Surveys (Section 3.1), Avian Fatality Surveys (Section 3.2), and for bias trials (Section 3.3). Risk index calculations will be provided in the annual report.

3.1 Avian Use Surveys

3.1.1 Methods

Avian Use Surveys were conducted monthly from November 2011 through June 2014, and will continue throughout the construction period and for three years after construction is complete. Each month, 63 randomly selected survey points are completed, including 31 inside existing array areas, 18 along existing overhead power lines, 10 in grassland reference sites and 4 at energized equipment (substation). At each point, a 10 minute bird use count is conducted within a 50 meter radius of the surveyor. Avian Use Survey points are randomly selected each month across all six phases of the project and in offsite grassland reference areas (Exhibit 3).

3.1.2 Results

The four Survey Area Categories used as treatment types in this study comprise different habitat elements that influence species composition, abundance, and richness.

The Array Area category includes point counts conducted within solar array areas during active construction and in completed form. The habitat consists of rows of passive (non-moving) photovoltaic solar panels mounted to steel racking ranging from approximately 2 to 5 feet off the ground. The ground is seeded with a native seed mix to revegetate array areas to naturalized grassland habitat; vegetation density varied from 0 to 60 percent cover. Array Area survey point areas may also include perimeter fences, photovoltaic combining switchgear houses, as well as array roads.

The Energized Equipment category includes point counts conducted around the perimeter of the substation. The survey area includes the substation perimeter fence, transformers, power lines, and other electrical components. Within the substation fence the ground is gravel with no vegetation. Outside the perimeter fence, the ground is bare dirt with some patches of grass.

Overhead Powerline surveys represent areas underneath medium-voltage collector lines within the project. Vegetation varies depending on location; most powerlines are along array or perimeter access roads, however some locations are outside the fenced project areas in annual grassland habitat.

Reference Sites are composed of annual grassland habitat. They included point counts conducted on annual grassland in mitigation lands owned by California Department of Fish and Wildlife or Stewardship Land not developed by TSF.

In April, May, and June 2014, 189 avian point counts were conducted in the four survey area categories totaling 366.8 acres of survey area. During these surveys, 21 different bird species were observed (Table 6). The 10 most abundantly detected species, listed in decreasing order of abundance, were: horned lark (568 detections), common raven (46), house finch (36), western kingbird (18), mourning dove (12), European starling (10), turkey vulture (7), brewer's blackbird (6), tricolored blackbird (6), and red-tailed hawk (5). The most frequently encountered species, the horned lark, was detected more than twelve times as often as that of that of the second most frequently encountered species, the common raven. Horned larks are abundant year-around residents that nested within and around the TSF project site in high numbers in spring 2014. Both the horned lark and common raven were detected in high numbers in all project component categories and up to 51 percent less frequently in the Reference Site category.

TABLE 6. SPECIES COMPOSITION AND ABUNDANCE. All bird species detected during Avian Use Surveys in April, May and June 2014, with the average number of bird use detections per observation point calculated for each of the four survey area categories. Total detections for each species and each survey area type are provided in far right column and bottom row. Species are listed in decreasing order of abundance according to the total detections column.

Species	**Array Area** Ave. Detections per Obs. Pt.	**Energized Equipment** Ave. Detections per Obs. Pt.	**Overhead Powerline** Ave. Detections per Obs. Pt.	**Grassland/ Reference** Ave. Detections per Obs. Pt.	**Total Species Detections**
Horned Lark	4.63	1.42	1.06	2.10	568
Common Raven	0.25	0.17	0.31	0.13	46
House Finch	0.26	1.00	0.00	0.00	36
Western Kingbird	0.01	0.42	0.17	0.10	18
Mourning Dove	0.12	0.08	0.00	0.00	12
European Starling	0.05	0.08	0.06	0.03	10
Turkey Vulture	0.00	0.00	0.11	0.03	7
Brewer's Blackbird	0.02	0.00	0.07	0.00	6
Tricolored Blackbird	0.06	0.00	0.00	0.00	6
Red-tailed Hawk	0.02	0.00	0.06	0.00	5
Western Meadowlark	0.03	0.00	0.00	0.03	4
House Sparrow	0.00	0.08	0.04	0.00	3
Savannah Sparrow	0.02	0.00	0.02	0.00	3
Bullock's Oriole	0.02	0.00	0.00	0.00	2
Hummingbird sp.	0.01	0.00	0.02	0.00	2
Barn Swallow	0.01	0.00	0.00	0.00	1
Cliff Swallow	0.00	0.00	0.00	0.03	1
Eurasian Collared-Dove	0.00	0.08	0.00	0.00	1
Prairie Falcon	0.01	0.00	0.00	0.00	1
Say's Phoebe	0.00	0.00	0.00	0.03	1
Vesper Sparrow	0.01	0.00	0.00	0.00	1
Total Avian Detections	**516**	**40**	**103**	**75**	**734**

Species richness was calculated as the average number of species detected at each Observation Point. Among the treatment types, Energized Equipment had the highest species richness with an overall average of 1.67 species detected per Observation Point. Array Area had the next highest with an average of 1.30 species. Reference Site and Overhead Powerline categories were similar, with 0.80 and 0.93 species detected per Observation Point (Table 7 and Figure 2). The Energized Equipment species richness is about twice that of the undeveloped grassland sites.

Bird Utilization Rate (BUR) is calculated as the average number of birds observed per Observation Point count. Bird Utilization Rate is calculated for the four Survey Area Categories for April – June 2014 (Table 7 and Figure 2). Array Areas had the highest BUR at 5.55 birds per Observation Point. With 3.33 and 2.50 birds per Observation Point, Energized Equipment and Reference Site categories had the second and third highest BUR, and Overhead Powerline had the lowest BUR at 1.91 birds per Observation Point.

TABLE 7. AVIAN USE SURVEY POINT COUNTS AND DETECTIONS. Avian use survey point count data is provided for number of observation point counts, total area surveyed, total number of species detected, species richness and bird utilization rate. All results are from data collected in April, May and June 2014.

Type	**Number of Obs. Pt. Counts**	**Total Area Surveyed (Acres)**	**Total No. Species**	**Ave. No. Species per Obs. Pt (Species Richness)**	**Ave. No. Birds per Obs. Pt (BUR)**
Array Area	93	180.49	16	1.30	5.55
Energized Equipment	12	23.29	8	1.67	3.33
Overhead Powerline	54	104.80	10	0.93	1.91
Reference Site	30	58.22	8	0.80	2.50
Total	**189**	**366.80**	**21**	**1.14**	**3.88**

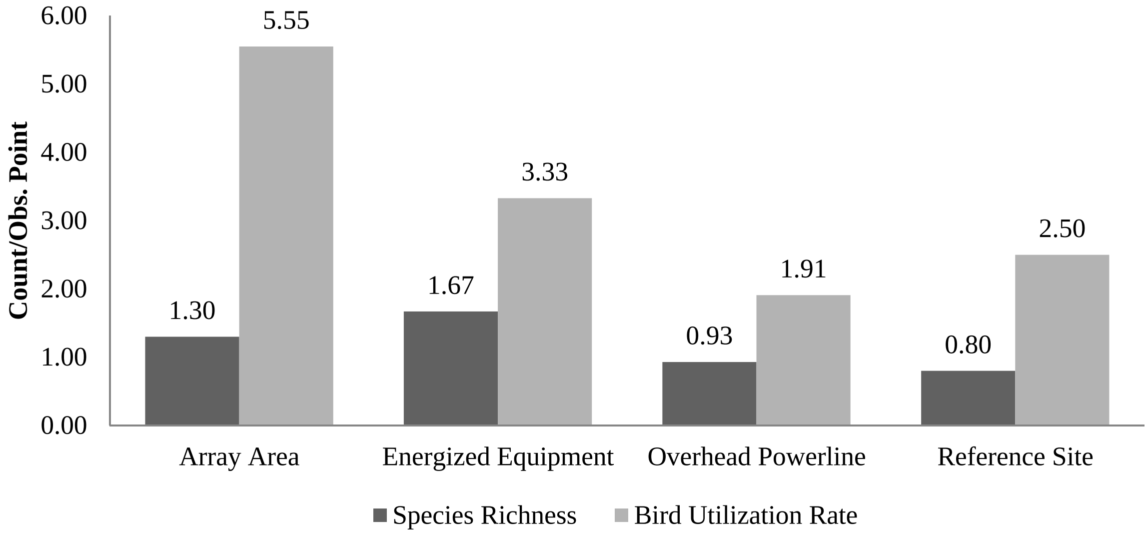

FIGURE 2. SPECIES RICHNESS AND BIRD UTILIZATION RATE. Species richness and bird utilization rate are provided for each of the four survey area categories.

.

3.2 Avian Fatality Surveys

3.2.1 Methods

Avian Fatality Surveys commenced upon completion of the first project components. Avian Fatality Surveys are conducted at randomly selected locations within four different survey area categories: Array Area, Overhead Powerline, Energized Equipment (Substation) and Reference Site. Search plots for Array Area, Reference Site, and Overhead Powerline were defined as a transect 14 feet wide and 480 feet long, or the area of a typical aisle in a PV array. The area searched in the Array Area and Reference Site each month are equivalent to approximately three PV arrays. The search plot for Energized Equipment is the entire area of the substation, which is 4.48 acres. All survey areas except Energized Equipment are randomly selected using an ArcGIS random point generator having defined areas as the constraining polygon. Avian Fatality Surveys are conducted within the same search plots each day for seven consecutive days every month. Repetitive surveys increase the chance of finding fatalities in a given area before predators remove the carcass, and also facilitate per day calculations.

3.2.2 Results

Each month, April through June 2014, we completed walking Avian Fatality Surveys for all transects within each of the Survey Area Categories for seven consecutive days each. Reference Site search plots were completed for seven consecutive days each, totaling 72.5 linear miles (123.1 acres) each month. Array Area search plots were completed for seven consecutive days each, totaling 72.5 linear miles (123.1 acres) each month. Overhead Powerline search plots were completed for seven consecutive days each, totaling 7.6 linear miles (13.0 acres) for April and May. In June, the powerline survey effort was increased to a total of 15.3 linear miles (25.9 acres). Energized Equipment was also surveyed for seven consecutive days, totaling 31.4 acres. See Exhibit 4 in Section 5.0 for a map of Avian Fatality Survey areas for April to June 2014.

Three months of surveys yielded a total distance of 465.7 linear miles and coverage of 884.6 acres. These surveys resulted in discovery of five fatalities, one each in Reference Site and Overhead Powerline, and three in Array Area. Fatality rates were calculated per search plot and mile walked (Table 8). Although only one fatality was found along the Powerline, it had the fewest search plots and therefore the highest fatality rate of 0.0030 fatalities/search plot. Array Areas had 3 fatalities and the second highest fatality rate of 0.0013 fatalities/search plot. In contrast, the same total acreage surveyed in Reference Site yielded only one fatality and therefore had a lower fatality rate of 0.0004 fatalities/search plot.

TABLE 8. BIRD FATALITY RATE. The survey results and efforts are indicated for each of the four survey area categories for the second quarter of 2014.

Survey Area Category	**Linear Miles**	**Acres**	**Search Plots**	**Total Fatalities**	**Fatality/ Search Plot**	**Fatality/ Mile**
Array Area	217.6	369.3	2394	3	0.0013	0.0138
Overhead Powerline	30.5	51.9	336	1	0.0030	0.0328
Reference Site	217.6	369.3	2394	1	0.0004	0.0046
Energized Equipment	-	94.1	21	0	0.0000	-
Total	**465.7**	**884.6**		**5**		

Cause of death was recorded for all fatalities, when known. The five fatalities documented during Avian Fatality Surveys in April, May, and June 2014 were classified as predation, collision, or unknown. The collision on the powerline was not confirmed, but was given a greater than 50 percent confidence level. Since it is difficult to determine cause of death with certainty, recent guidance from the U.S. Fish and Wildlife Service suggests attributing cause of death to a specific factor and including a confidence percent to indicate how confident the determination was (Table 9; A. Beck and T. Dietsch 2013). Predation as a cause of death is likely higher than reported, as often times a feather pile could not be confidently linked to a predation event as opposed to a scavenging event.

TABLE 9. CAUSE OF DEATH FOR AVIAN FATALITY SURVEY RESULTS. Cause of death tallied for avian fatalities detected within each of the four survey area categories, April – June, during formal avian fatality surveys. Percentages indicate confidence level.

Survey Area Category	Unknown	Predation Probable (>50%)	Collision Probable (>50%)
Array Area	0	3	0
Overhead Powerline	0	0	1
Reference Site	1	0	0
Energized Equipment	0	0	0
Total	**1**	**3**	**1**

3.3 Scavenger/Carcass Removal Trials and Searcher Efficiency Trials

3.3.1 Scavenger/Carcass Removal Trial

Scavenger/carcass removal trials were conducted in May and June 2014. Japanese quail carcasses were randomly placed by the trial administrator in Array Areas. Scavenger trials for Reference Site will be completed during the next quarter. The carcasses were numbered and labeled with a small band of green tape around one leg. Remote wildlife cameras were placed on half of the quail to document the scavenging animal.

Carcass monitoring procedures outlined in the ABPP/BMAP require carcasses to be checked the first three consecutive days after placement, twice a week for the next two weeks, and then once a week for the remainder of the 60 day trial. Monitoring stopped when 100 percent of the carcasses were scavenged. Upon routine monitoring of the carcasses, notes are recorded of the status and condition of the carcass. In these trials, with the exception of a few feathers, the carcass was simply present or not present.

As suspected, carcasses did not last long after they were placed in the Array Areas by the trial administrator. Eighty-five percent of the carcasses were scavenged within the first three days. All carcasses were scavenged within 2 weeks of being placed in the field (Figure 3). Of the ten cameras monitoring quail carcasses, seven captured photos of the predators, with the most common being ravens (Figure 4). Other scavengers include a bobcat, turkey vulture, coyote, and San Joaquin kit fox.

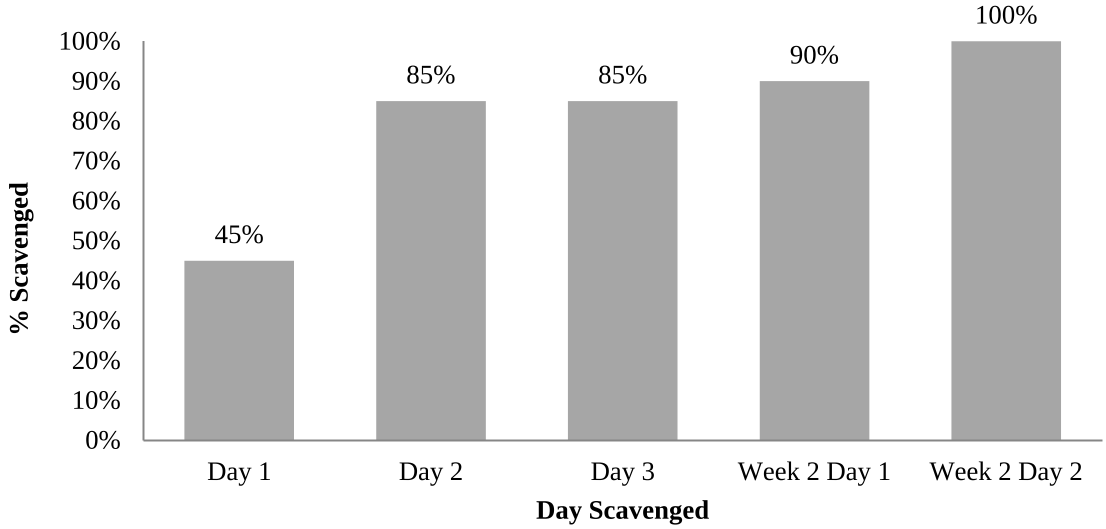

FIGURE 3. PERCENT SCAVENGED BY DAY (CUMULATIVE)-ARRAY AREA. Cumulative percent of carcasses scavenged in Array Areas by day in the June 2014 onsite trial. Percent scavenged is out of 20 quail placed.

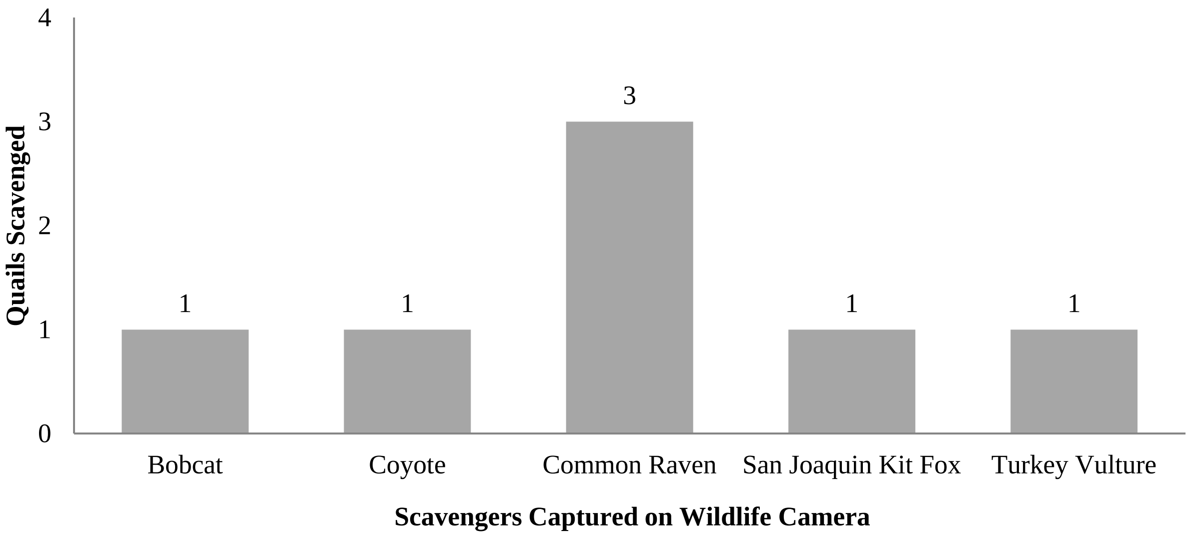

FIGURE 4. SCAVENGERS IDENTIFIED VIA REMOTE CAMERA. Number of quail carcasses scavenged by each predator out of seven photo captures.

3.3.2 Searcher Efficiency Trial

Searcher efficiency trials were conducted in June 2014. Prior to the commencement of the day's Avian Fatality Surveys, Japanese quail carcasses were randomly placed by the trial administrator in the search plots of the scheduled Avian Fatality Surveys, in Array Areas and Reference Site search plots. The trial was conducted blind, meaning carcasses were placed without the knowledge of the surveyors.

After the survey crew completed the day's surveys, the trial administrator performed a follow-up on all the carcasses placed prior to the trial. This was to determine how many of the original carcasses were in place, therefore available for detection, and how many carcasses had been scavenged by wildlife. The carcasses determined to have been scavenged by the time of the follow-up were removed from the detection rate calculation, since it could not be confirmed that the carcass was present when the surveyors were in that area.

Figure 5 provides detection rates for each Array Areas and Reference Site carcass placement in the trial. The detection rate is calculated by dividing the number of carcasses found by the number of carcasses placed minus any that were predated. Array Area detection rate was 60 percent, while Reference Site detection rate averaged 35 percent (Figure 5). Detection rate was higher in the Array Area search plots than in the Reference Site plots most likely because of less vegetation cover that provided greater visibility of the ground surface.

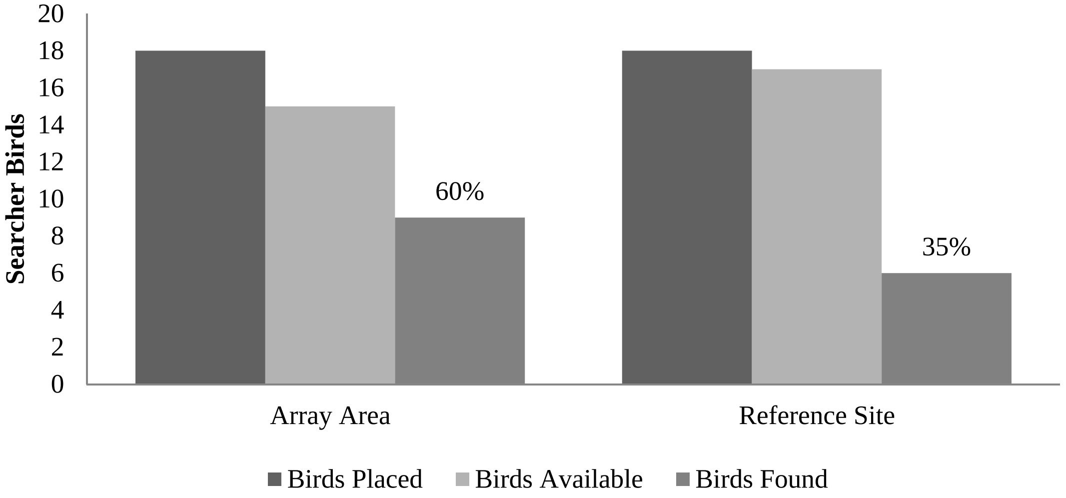

Figure 5. SEARCHER EFFICIENCY TRIAL. Detection rates are provided for Array Area and Reference Site searcher efficiency trials.

3.4 Discussion

The 2014 nesting season resulted in detection of a high number of nests in and near active construction areas, most notably for the horned lark. Horned lark nest success in 2014 was 23 percent, which is comparable to that of 2013 (21.5 percent), even though there were significantly more nests present in 2014 (71 nest) than in 2013 (14 nests). As with last year, predation was the primary cause of nest failure.

During this 2nd quarter reporting period, April, May, and June 2014, unadjusted Fatality Rate in Array Areas was three times higher than that recorded at the grassland Reference Site (0.0013 and 0.0004, respectively). Bird Utilization Rate was more than twice as high in the Array Areas (5.55 birds per Observation Point) than Reference Site (2.50 birds per Observation Point). The Fatality Rate calculated for this quarterly report was not adjusted for searcher and scavenger bias. Searcher efficiency in Array Areas found 1.7 times as many carcasses as in Reference Sites. This highlights the importance of obtaining accurate bias data and making final calculations incorporating the bias data, and the variation that can occur season to season and year to year. The annual report will provide bias adjusted Fatality Rates for all project components over the year. Searcher efficiency and scavenger trials will continue through 2014 to better refine bias data.

One raven was found dead beneath the power lines, with cause of death suspected to be collision (confidence of that determination was listed as probable, >50%). Ravens frequent the power lines, roosting on the poles and lines and nesting on several poles. It was not determined what the raven likely collided with, power pole or power line. A second raven was found dead at the base of a power pole, with cause of death confidently linked to electrocution based on physical examination of the carcass (singed feathers, entry and exit wounds). O&M technicians inspected the pole components and found the wildlife protector cap to be properly situated and no other evidence to suggest the cause of the electrocution. Continued monitoring and increased power line survey effort are being implemented to determine if these are isolated events or if a specific cause can be determined.

2014 Third Quarterly Report

COA 62 Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan Quarterly Report

October 1, 2014

Discussion

The enclosed report has been prepared to address the reporting requirements for Condition of Approval (COA) 62 Bird Monitoring and Avoidance Plan (BMAP). This plan is merged with the Avian and Bat Protection Plan (ABPP), comprising a comprehensive avian management plan for the Topaz project.

In response to COA 62, the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP/BMAP) has been prepared, which further describes the approach to implementing the condition requirements.

COA 62 requires quarterly and annual reports. Quarterly reports are required during construction and for three years following the beginning of plant operation.

Following the completion of the fourth quarter of monitoring the biologist shall prepare an annual report that summarizes the year’s data, analyzes any project-related bird fatalities or injuries detected, and provides recommendations (in consultation with the County) for future monitoring and any adaptive management actions needed.

Quarterly Reportable Items

COA 62 BMAP requires quarterly reports describing the dates, durations, and results of monitoring and data collection. The quarterly reports shall provide a detailed description of any project-related bird or wildlife deaths or injuries detected during the monitoring study or at any other time.

Report Data

Attached is the quarterly report prepared by Althouse & Meade (COA 62 Year 3 Third Quarter July 01-September 30, 2014 for ABPP and BMAP).

1.0 Introduction

This Year 3 Third Quarter report provides bird and bat information as specified in the Topaz Solar Farms Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP and BMAP; Althouse and Meade, Inc. June 2011). Section 5.5 of the ABPP and BMAP describes information to be included in reports and requires quarterly reports to be submitted to the County of San Luis Obispo (County), U.S. Fish and Wildlife Service (USFW) and the California Department of Fish and Wildlife (CDFW). The Avian and Bat Protection Plan (ABPP; Section 2.0) and Bird Monitoring and Avoidance Plan (BMAP; Section 3.0) are requirements of County of San Luis Obispo Conditions of Approval (COA) 61 and 62, and were prepared in consultation with USFWS and CDFW.

1.1 Construction Status

Construction of Blocks 1-9 was completed in 2013, and Blocks 10-19 were completed in 2014 by the end of September (Table 1). All completed blocks were transferred to and are now managed by Operations and Maintenance (O&M). Exhibit 1 illustrates construction status through September 2014.

TABLE 1. CONSTRUCTION STATUS BY BLOCK. Date of transfer to O&M is provided for Blocks 1-17. Bold indicates transfer during 2^{nd} quarter.

Block(s)	Month and Year Transferred to O&M	Block(s)	Month and Year Transferred to O&M
1	March 2013	12	May 2014
2	March 2013	13	May 2014
3	March 2013	14	January 2014
4	April 2013	15	February 2014
5	April 2013	16	May 2014
6	March 2013	17	June 2014
7	May 2013	18	**August 2014**
8	June 2013	19	**August 2014**
9	July 2013	20	-
10	March 2014	21	-
11	May 2014	22	-

2.0 Avian and Bat Protection Plan

The ABPP monitoring program compiles general information on bird and bat presence, interactions with facility components, injuries, and mortality at the Topaz Solar Farms (TSF) project. During construction phases of the project this task is completed by the project biologists, as part of routine daily biological monitoring. In blocks under Operations and Maintenance (O&M) control, data is collected from a variety of sources, including pre-activity surveys, O&M technician reports, and during field work conducted for BMAP studies. Information regarding the detailed bird use and mortality risk assessment study is reported in Section 3.0.

For the ABPP, this quarterly report provides information collected during active construction in Blocks 18-22, spanning the period from June 1 through September 30, 2014

2.1 General Bird Surveys

2.1.1 Methods

General bird surveys are conducted on and around active construction areas of TSF project site on a daily basis seven days a week throughout the year by project biologists. Lists of bird species observed by each biological monitor are recorded on daily construction monitoring forms, which are then scanned, archived, and reviewed by project ornithologists Peter Gaede and Jason Dart.

2.1.2 Results

Monitors recorded a total of 48 species of birds in July, August and September 2014; an additional 3 birds were not identified to species level, but general bird type category was known and is included in the following tallies. Of the 48 identified species, 6 were waterbirds and 12 were raptors. Some of the 6 waterbird species were observed in lands surrounding Topaz including a private pond less than a thousand feet from TSF, and others were observed flying over TSF without using project features as habitat. Demolition of the TSF dust control pond (DCP) occurred during the last reporting period; the DCP was where most onsite waterbird detections were recorded. Table 1 lists all bird species observed in this quarter with information on observation frequency.

TABLE 2. JULY – SEPTEMBER 2014 GENERAL BIRD SURVEY RESULTS. All bird species recorded this quarter are listed. Top twenty species most frequently observed, waterbirds, and raptors are indicated.

2.2 Nesting Activity

2.2.1 Methods

Focused nest surveys were conducted daily on and around the TSF project components under construction by biological monitors starting February 1, for the 2014 monitoring year. All nest surveys were conducted on foot by trained biologists. Strategically selected array areas near active construction were identified at the beginning of each week where surveyors walked all array rows searching for nests on the ground or on structures. Additionally, an area 300 feet around all perimeter fences of active construction areas was surveyed twice per week, per the approved Nesting Bird Management Plan (Althouse and Meade, Inc. 2013). Laydowns and move-on areas were surveyed as often as possible to prevent birds establishing nests in equipment and materials. Nests were also found by construction personnel in their work areas or incidentally found by biologists while monitoring construction activities. Nest starts were removed when the presence of a complete nest would conflict with construction activities or would present a danger to the birds. All nests and nest starts were documented. Nests identified from July to September 2014 in active construction areas are included in this report.

2.2.2 Results

The results of surveys from July through September 2014 are provided in Table 3. Other species identified nesting offsite (e.g. Mitigation Lands, future project lands, or areas managed by Operations and Maintenance) are not included in this table. No nest starts were removed during this reporting period.

Two house finch nests were documented in active construction areas during the reporting period, both of which fledged successfully (Table 3).

Exhibit 2 in Section 5.0 is a map of bird nests in and near areas of active construction July through September 2014.

TABLE 3. JULY – SEPTEMBER 2014 BIRD NESTS. Active bird nests detected at Topaz Solar Farms from July to September 2014 in active construction areas.

Species	Final Status	Number of Nests	Percent of Total
House Finch	Fledged	2	100

2.3 Avian and Other Wildlife Mortality

General biological monitoring of the Topaz work area documented bird, bat, and other wildlife mortality, as required by COA 62. All mortality identified on site during this reporting period is provided in Table 4. Cause of death is reported when known. Several of the avian fatalities identified were feather spots, so cause of death could not be confirmed. This table includes all fatalities found in active construction areas as well as areas managed by Commissioning or Operations and Maintenance.

TABLE 4. JULY – SEPTEMBER 2014 AVIAN AND OTHER WILDLIFE MORTALITY. Bird and other wildlife mortality detected at the Topaz Solar Farms from April to June 2014. Asterisk indicates found during formal fatality surveys.

Month	Species	Location	Cause of Death
July	Gopher Snake	Phase 6 Laydown	Vehicle Strike
	Common Raven*	Block 2	Predation
	Gopher Snake	Block 22	Probable Vehicle Strike
	Unknown Mouse (5)	Phase 6 Laydown	Abandonment
	McKittrick Pocket Mouse	Energy Place	Unknown
	Domestic Chicken	Block 17	Predation
August	Deer Mouse (4)	Phase 6 Laydown	Material Crush
	Horned Lark*	Block 7	Unknown
	Horned Lark*	Block 8	Unknown
	Horned Lark*	Block 8	Unknown
	Common Raven	Block 7	Possible Predation
	Rock Pigeon	Block 21	Probable Exhaustion
	Heermann’s Kangaroo Rat	Block 17	Drowning
	Unknown Mouse (5)	Secure Laydown	Exposure
September	Gopher Snake	Block 22	Vehicle Strike
	Killdeer*	Block 19	Unknown
	Common Raven*	Block 11	Unknown
	Domestic Cat	Secure Laydown	Unknown
	Desert Cottontail	Block 22	Predation

2.4 Adaptive Management

No adaptive management practices were implemented during the period from July through September 2014.

2.5 Bat Surveys

2.5.1 Methods

Acoustic monitoring surveys for bats on the project site were conducted at least one night per month using a Pettersson D240x (Pettersson Elektronik, Sweden) bat detector and Sonobat® (v.3.1 US west; DNDesign, Arcata, CA) acoustic analysis software. Sound frequencies in the range utilized by bats (10 to 120 kHz) were detected and synthesized into time-expanded sound files and analyzed by Sonobat® software. Surveys were initiated near dusk, when bats commonly begin foraging. Monitoring periods for each survey were limited to the battery life of the Pettersson detector and typically ranged from three to six hours depending on the number of sound files detected. On July 30 and August 15 the detector was placed on the perimeter fence just east of production well 7 (PW7). On September 2, 3, and 18 the detector was deployed in conjunction with night work for the medium voltage overhead collection line. On September 2 and 3 the detector was placed in the Phase 5 Move On area near the lights associated with the night work, and on September 18 it was deployed in Block 8. On September 29, the detector was placed on the perimeter fence in the northeast corner of Block 21. All detected bat calls were identified to species with a discrimination probability of 0.95 or higher using Sonobat® software.

2.5.2 Results

From July through September, six species of bat were detected at Topaz Solar Farms (Table 5). The majority of detections were Mexican free-tailed bats (*Tadarida brasiliensis*), which were detected on nearly every survey night. In addition, canyon bats (*Parastrellus hesperus*) were detected in both July and August and have been previously detected at Topaz Solar Farms during acoustic survey events. Silver-haired bat (*Lasionycteris noctivagans*), a CDFW Special Animal, and big brown bat (*Eptesicus fuscus*) were only detected during one night, in September. Western small-footed myotis (*Myotis ciliolabrum*), a CDFW Special Animal, was detected in July and September. Pallid bat (*Antrozous pallidus*), a CDFW Species of Special Concern, was detected in July and August with only a single detection on each survey night. No bat roosts are known to be present within the Topaz project site.

TABLE 5. ACOUSTIC BAT SURVEYS AT TOPAZ SOLAR FARMS FROM JULY TO SEPTEMBER 2014. Survey dates, bat species detected, number of detections, and special status designations from CDFW and Western Bat Working Group (WBWG) are provided.

Survey Date	**Location**	**Total Detections**	**Common Name**	**Scientific Name**	**CDFW Status**	**WBWG Status**
7/30/2014	PW7 near Block 20	1	Pallid bat	*Antrozous pallidus*	SSC	High

9/29/2014	Northeast corner of Block 21	3	Canyon bat	*Parastrellus hesperus*	None	Low
9/29/2014	Northeast corner of Block 21	1	Pallid bat	*Antrozous pallidus*	SSC	High

2.5.1 Species descriptions

Pallid bats are large, long-eared bats occurring throughout the state from deserts to moist forests. They primarily roost in crevices where they can retreat from view, frequently occurring in oak woodlands where they roost in tree cavities. These roosts are generally day or night roosts for one or a few bats. Attics may be used as roosts and during hot days they may emerge from crevices and roost on open rafters. Communal wintering or maternity colonies are more common in rock crevices and caves. In the Carrizo Plain area, nearby trees, old structures, cliff faces, and rocky outcropping may provide roosting sites for pallid bats.

Big brown bats are medium to large sized bats and have a wide distribution extending from Canada to northern South America. They are considered common within their range and tend to roost in man-made structures such as bridges, barns and attics. Females roost communally with males at hibernation sites and roost separately from males in spring and summer. Big brown bats would most likely roost in old structures in the Carrizo Plain area.

Silver-haired bats are medium-sized bats with black or dark brown hairs that are silver-tipped. It is a forest-dwelling species generally thought to be concentrated in the northern half of the state and considered relatively uncommon throughout much of its range. However, there are reports of this species in San Luis Obispo, Santa Barbara, and Ventura counties. This species typically roosts in trees, but has also been observed using structures such as attics and sheds. In the Carrizo Plain area, silver-haired bats most likely roost in the woodlands along the western periphery of the plain.

Western small-footed myotis is a small bat that occurs over most of California and the western United States. It roosts singly or in small groups in rocky cliffs, caves, mines, and man-made structures. Small-footed myotis commonly forages over water; both natural and man-made. In the Carrizo Plain area, they may roost in rocky cliffs or old structures.

Canyon bats, formerly called western pipistrelles, are one of the smallest bats in California. They are typically considered a desert species and primarily roost in canyon and cliff sides, but may also roost in caves, mines or buildings. Canyon bats tend to roost singly or in very small groups. They are among the most diurnal of bats and often begin foraging before sunset and continue until well after dusk. Canyon bats are considered common throughout their range. In the Carrizo Plain area, they likely roost in rocky outcroppings, cliff faces, and old structures.

Mexican free-tailed bats primarily roost in caves, but are frequently found in cavities under bridges and in buildings, where they roost gregariously. They may also roost singly or in small groups in large tree cavities. This species is common throughout San Luis Obispo County. Maternity colonies form in spring and pups are born in the summer. Mexican free-tailed bats are one of the most widely distributed mammalian species in the Western Hemisphere and may fly more than 50 km a night to reach foraging areas. In the Carrizo Plain area, old barns and outbuildings likely provide roosting sites for Mexican free-tailed bats.

3.0 Bird Monitoring and Avoidance Plan

The BMAP study analyzes avian use surveys and avian fatality surveys to produce a risk index for various project components deemed to be potentially dangerous to birds, including array areas, overhead power lines and the substation. Offsite grassland reference sites are used to gauge background mortality levels. Results are reported in this third quarter report for Avian Use Surveys (Section 3.1), Avian Fatality Surveys (Section 3.2), and for bias trials (Section 3.3). Risk index calculations will be provided in the annual report.

3.1 Avian Use Surveys

3.1.1 Methods

Avian Use Surveys were conducted monthly from November 2011 through September 2014, and will continue throughout the construction period and for three years after construction is complete. Each month, 63 randomly selected survey points are completed, including 31 inside existing array areas, 18 along existing overhead power lines, 10 in grassland reference sites and 4 at energized equipment (substation). At each point, a 10 minute bird use count is conducted within a 50 meter radius of the surveyor. Avian Use Survey points are randomly selected each month across all six phases of the project and in offsite grassland reference areas (Exhibit 3).

3.1.2 Results

The four Survey Area Categories used as treatment types in this study comprise different habitat elements that influence species composition, abundance and richness.

The Array Area category includes surveys conducted within solar array areas during active construction and in completed form. The habitat consists of rows of passive (non-moving) photovoltaic solar panels mounted to steel racking ranging from approximately 2 to 5 feet off the ground. The ground is seeded with a native seed mix to revegetate array areas to naturalized grassland habitat; vegetation density varied from 0 to 60 percent cover. Array Area survey point areas may also include perimeter fences, photovoltaic combining switchgear houses, as well as array roads.

The Energized Equipment category includes point counts conducted around the perimeter of the substation. The survey area includes the substation perimeter fence, transformers, power lines, and other electrical components. Within the substation fence the ground is gravel with no vegetation. Outside the perimeter fence, the ground is bare dirt with some patches of grass and forbs.

Overhead Powerline surveys represent areas underneath medium-voltage collector lines within the project. Vegetation varies depending on location. Most powerlines are along array or perimeter access roads, however some locations are outside the fenced project areas in annual grassland habitat.

Reference Sites are composed of annual grassland habitat. They included point counts conducted on annual grassland in mitigation lands owned and managed by California Department of Fish and Wildlife or Stewardship Land not developed by TSF.

In July, August, and September 2014, 189 avian point counts were conducted in the four Survey Area Categories totaling 366.8 acres of survey area. During these surveys, species composition consisted of 18 different bird species and one additional bird not identified to species. Bird abundance is examined as total number of detections per species as well as average number of detections per Observation Point (Table 6). The 10 most abundantly detected species, listed in decreasing order of total species detections, were: horned lark (527 detections), common raven (23), house finch (13), mourning dove (13), western sandpiper (13), turkey vulture (11), brewer's blackbird (10), house sparrow (9), loggerhead shrike (6), and Vaux's swift (4) and western meadowlark (4).

The most frequently encountered species, the horned lark, was detected more than 22 times as often as that of that of the second most frequently encountered species, the common raven. It was detected 3.4 times more frequently in Array Areas than in Reference Site grassland areas. The Energized Equipment category had the lowest average detections per Observation Point, which is consistent with lack of suitable foraging habitat in the substation. Common raven was detected at the Energized Equipment and Overhead Powerline categories most frequently. This is likely due to the availability of preferred perching locations on power poles.

TABLE 6. SPECIES COMPOSITION AND ABUNDANCE. All bird species detected during Avian Use Surveys in July, August, and September 2014 are listed, with the average number of bird use detections per observation point calculated for each of the four survey area categories. Total detections for each species and each survey area type are provided in far right column and bottom row. Species are listed in decreasing order of abundance according to the total detections column.

Species	**Array Area** Ave. Detections per Obs. Pt.	**Energized Equipment** Ave. Detections per Obs. Pt.	**Overhead Powerline** Ave. Detections per Obs. Pt.	**Grassland/ Reference** Ave. Detections per Obs. Pt.	**Total Species Detections**
Horned Lark	4.76	0.17	0.74	1.40	**527**
Common Raven	0.11	0.17	0.17	0.07	**23**
House Finch	0.14	0.00	0.00	0.00	**13**
Mourning Dove	0.11	0.00	0.00	0.10	**13**
Western Sandpiper	0.14	0.00	0.00	0.00	**13**
Turkey Vulture	0.06	0.00	0.04	0.10	**11**
Brewer's Blackbird	0.11	0.00	0.00	0.00	**10**
House Sparrow	0.00	0.33	0.09	0.00	**9**
Loggerhead Shrike	0.00	0.00	0.11	0.00	**6**
Vaux's Swift	0.04	0.00	0.00	0.00	**4**
Western Meadowlark	0.03	0.00	0.02	0.00	**4**
Unidentified Swift	0.00	0.00	0.06	0.00	**3**
Eurasian Collared-Dove	0.02	0.00	0.00	0.00	**2**
Western Kingbird	0.00	0.00	0.00	0.07	**2**
Burrowing Owl	0.00	0.00	0.00	0.03	**1**
Lesser Goldfinch	0.01	0.00	0.00	0.00	**1**
Rock Pigeon	0.01	0.00	0.00	0.00	**1**
Red-Tailed Hawk	0.01	0.00	0.00	0.00	**1**
Tree Swallow	0.01	0.00	0.00	0.00	**1**
Total Avian Detections	**518**	**8**	**53**	**66**	**645**

Species Richness was calculated as the average number of species detected at each Observation Point. Among the treatment types, Array Area had the highest species richness with an overall average of 0.96 species detected per Observation Point. Reference Site had the next highest with an average of 0.57 species, which was similar to Overhead Powerline at 0.54 species. Energized Equipment has the lowest with 0.42 species per observation point (Table 7 and Figure 1). The Array Area species richness is more than twice that of the Energized Equipment.

Bird Utilization Rate (BUR) is calculated as the average number of birds observed per Observation Point count. Bird Utilization Rate is calculated for the four Survey Area Categories for July – September 2014 (Table 7 and Figure 1). Array Areas had the highest BUR at 5.57 birds per Observation Point. With 1.77 and 1.22 birds per Observation Point, Reference Site and Overhead Powerline categories had the second and third highest BUR, and Energized Equipment had the lowest BUR at 0.67 birds per Observation Point.

TABLE 7. AVIAN USE SURVEY POINT COUNTS AND DETECTIONS. Avian use survey point count data is provided for number of observation point counts, total area surveyed, total number of species detected, species richness and bird utilization rate. All results are from data collected in July, August, and September 2014.

Type	**Number of Obs. Pt. Counts**	**Total Area Surveyed (Acres)**	**Total No. Species**	**Ave. No. Species per Obs. Pt (Species Richness)**	**Ave. No. Birds per Obs. Pt (BUR)**
Array Area	93	180.49	14	0.96	5.57
Energized Equipment	12	23.29	3	0.42	0.67
Overhead Powerline	54	104.80	6	0.54	1.22
Reference Site	30	58.22	7	0.57	1.77
Total Combined	**189**	**366.80**	**19**	**0.74**	**3.41**

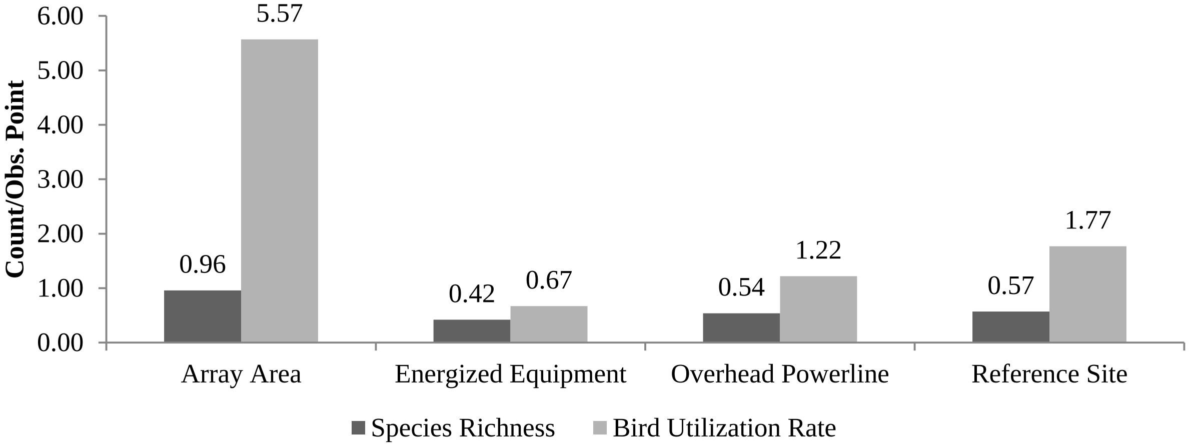

FIGURE 1. SPECIES RICHNESS AND BIRD UTILIZATION RATE. Species richness and bird utilization rate are provided for each of the four survey area categories.

.

3.2 Avian Fatality Surveys

3.2.1 Methods

Avian Fatality Surveys commenced upon completion of the first project components. Avian Fatality Surveys are conducted at randomly selected locations within four different survey area categories: Array Area, Overhead Powerline, Energized Equipment (Substation) and Reference Site. Search plots for Array Area, Reference Site and Overhead Powerline were defined as a transect 14 feet wide and 480 feet long, or the area of a typical aisle in a PV array. The area searched in the Array Area and Reference Site each month is equivalent to approximately three PV arrays. The search plot for Energized Equipment is the entire area of the substation, which is 4.48 acres. All survey areas except Energized Equipment are randomly selected using an ArcGIS random point generator having defined areas as the constraining polygon. Avian Fatality Surveys are conducted within the same search plots each day for seven consecutive days every month.[1] Repetitive surveys increase the chance of finding fatalities in a given area before predators remove the carcass, and also facilitate per day calculations.

3.2.2 Results

Each month, July through September 2014, we completed walking Avian Fatality Surveys for all transects within each of the Survey Area Categories for seven consecutive days each. Reference Site search plots were completed for seven consecutive days each, totaling 10.4 linear miles (17.6 acres) each day of surveys. Array Area search plots were completed for seven consecutive days each, totaling 10.4 linear miles (17.6 acres) each day. Overhead Powerline search plots were completed for seven consecutive days each, totaling 2.2 linear miles (3.7 acres) each day. Energized Equipment was also surveyed for seven consecutive days, totaling 4.5 acres each day. See Exhibit 4 in Section 5.0 for a map of Avian Fatality Survey areas for July to September 2014. In addition to these regular surveys, the Overhead Powerline in its entirety was surveyed on July 22, 2014; no fatalities were found. All acreage and mileage calculations reported exclude this one day survey.

Three months of surveys yielded a total distance of 504.0 linear miles and coverage of 953.8 acres. These surveys resulted in discovery of eight fatalities, two each in Reference Site and Overhead Powerline, and four in Array Area. Fatality rates were calculated per search plot and mile walked (Table 8). Although only two fatalities were found along the Powerline, it had the fewest search plots and therefore the highest fatality rate of 0.0038 fatalities/search plot. Array Areas had four fatalities and the second highest fatality rate of 0.0016 fatalities/search plot. In contrast, the same total acreage surveyed in Reference Site yielded two fatalities and therefore had a lower fatality rate of 0.0008 fatalities/search plot.

---

[1] The last day of September surveys was missed and was therefore searched for an additional two consecutive days the later in the month. No fatalities were found during these days.

TABLE 8. BIRD FATALITY RATE. The survey results and efforts are indicated for each of the four survey area categories for the third quarter of 2014.

Survey Area Category	**Linear Miles**	**Acres**	**Search Plots**	**Total Fatalities**	**Fatality/ Search Plot**	**Fatality/ Mile**
Array Area	228.0	386.9	2508	4	0.0016	0.0175
Overhead Powerline	48.0	81.5	528	2	0.0038	0.0417
Reference Site	228.0	386.9	2508	2	0.0008	0.0088
Energized Equipment	-	98.6	22	0	0.0000	-
Total Combined	**504.0**	**953.8**		**8**		

Cause of death was recorded for all fatalities, when known. The eight fatalities documented during Avian Fatality Surveys in July, August, and September 2014 were classified as predation or unknown. Since it is difficult to determine cause of death with certainty, recent guidance from the U.S. Fish and Wildlife Service suggests attributing cause of death to a specific factor and including a confidence percent to indicate how confident the determination was (Table 9; A. Beck and T. Dietsch 2013). Predation as a cause of death is likely higher than reported, as often times a feather pile could not be confidently linked to a predation event as opposed to a scavenging event.

TABLE 9. CAUSE OF DEATH FOR AVIAN FATALITY SURVEY RESULTS. Cause of death tallied for avian fatalities detected within each of the four survey area categories, July – September, during formal avian fatality surveys. Percentages indicate confidence level.

Survey Area Category	**Unknown**	**Predation Valid (>90%)**	**Predation Possible (1-50%)**	**Total**
Array Area	3	1	0	**4**
Overhead Powerline	2	0	0	**2**
Reference Site	1	0	1	**2**
Energized Equipment	0	0	0	**0**
Total Combined	**6**	**1**	**1**	**8**

3.3 Scavenger/Carcass Removal Trials and Searcher Efficiency Trials

3.3.1 Scavenger/Carcass Removal Trial

Scavenger/carcass removal trials were conducted in July and August 2014. Japanese quail carcasses were randomly placed by the trial administrator in Reference Site areas. Scavenger trials for Array Areas were completed during the last quarter. The carcasses were numbered and labeled with a small band of green tape around one leg. Remote wildlife cameras were placed on half of the quail to document the scavenging animal.

Carcass monitoring procedures outlined in the ABPP/BMAP require carcasses to be checked the first three consecutive days after placement, twice a week for the next two weeks, and then once a week for the remainder of the 60 day trial. Monitoring stopped when 100 percent of the carcasses were scavenged. Upon routine monitoring of the carcasses, notes are recorded of the status and condition of the carcass. In these trials, with the exception of a few feathers, the carcass was simply present or not present.

As expected, carcasses did not last long after they were placed in the Reference Site by the trial administrator. Eighty-five percent of the carcasses were scavenged within the first three days. All carcasses were scavenged within 2 weeks of being placed in the field (Figure 2). Of the ten cameras monitoring quail carcasses, eight captured photos of the suspected scavengers, with the most common being San Joaquin kit fox (Figure 3). Other scavengers include American badger, coyote, and common raven.

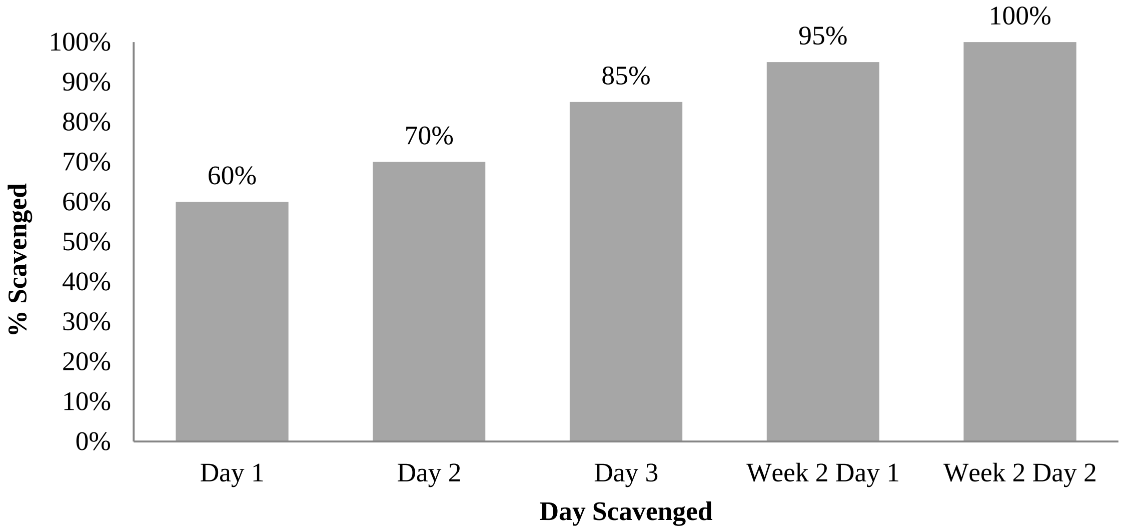

FIGURE 2. PERCENT SCAVENGED BY DAY (CUMULATIVE)-ARRAY AREA. Cumulative percent of carcasses scavenged in Array Areas by day in the July and August 2014 offsite trial. Percent scavenged is out of 20 quail placed.

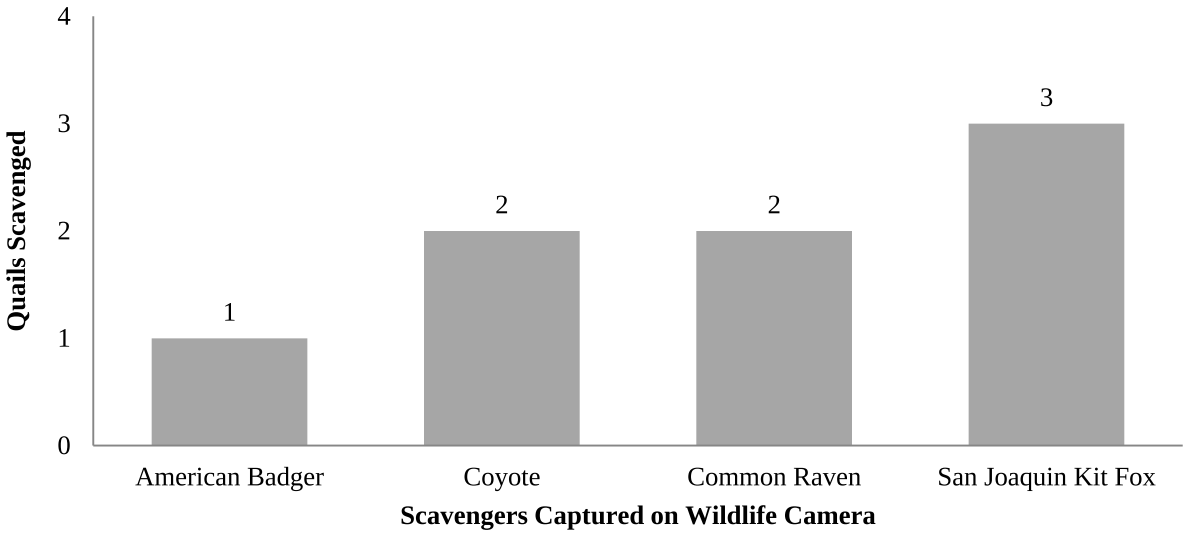

FIGURE 3. SCAVENGERS IDENTIFIED VIA REMOTE CAMERA. Number of quail carcasses scavenged by each suspected predator out of eight photo captures.

3.3.2 Searcher Efficiency Trial

Searcher efficiency trials were not conducted during this reporting period.

3.4 Discussion

The only bird nests that remained active past June were house finch nests. House finch nests were particularly common in staged equipment and material stacks.

During this 3rd quarter reporting period, July, June, and August 2014, unadjusted Fatality Rate in Array Areas was twice as high as that recorded at the grassland Reference Site (0.0016 and 0.0008, respectively). Bird Utilization Rate was more than three times as high in the Array Areas (5.57 birds per Observation Point) than Reference Site (1.77 birds per Observation Point). The data indicates more birds were present and more birds died within the Array Areas than in the Reference Site areas. The Overhead Powerline surveys yielded the highest unadjusted Fatality Rate, although collisions or electrocution were not suspected as the cause of death. Additionally, a comprehensive search conducted in one day along the entire power line did not detect any fatalities. The Fatality Rates calculated for this quarterly report were not adjusted for searcher and scavenger bias. The annual report will provide bias adjusted Fatality Rates for all project components over the year. Searcher efficiency and scavenger trials will continue through 2014 to better refine bias data.

The third quarter general bird surveys listed nearly half as many species as were listed in the second quarter. The Bird Utilization Rates and Species Richness values were also much less in all categories this quarter except for Array Areas. We suspect this is due to the record drought in California, and seasonal differences between spring and summer seasons with respect to bird presence. There was less available vegetation, water, and food this year for the birds and even less during this reporting period which was the hottest and driest part of the year.

Annual Report

COA 62 Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan

February 13, 2013

Discussion

This report has been prepared to address the reporting requirements for Condition of Approval (COA) 62 Bird Monitoring and Avoidance Plan (BMAP). The BMAP report was prepared to include bats and the title revised to the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP).

In response to COA 62, the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP) has been prepared, which further describes the approach to implementing the condition requirements.

COA 62 requires quarterly and annual reports. Following the completion of the fourth quarter of monitoring the biologist shall prepare an annual report that summarizes the year's data, analyzes any project-related bird fatalities or injuries detected, and provides recommendations (in consultation with the County) for future monitoring and any adaptive management actions needed.

Annual Reportable Items

COA 62 ABMP requires specific significance thresholds that would trigger Adaptive Management will be defined in the Year 1 annual report based on analysis of the Year 1 data, in consultation with the County, CDFW and USFWS. Significance thresholds will be based on statistical comparison of Project Site data and offsite reference plot data. Comparison with reference plots will provide insight regarding the significance of any detected fatalities, so that thresholds can be assigned with confidence. If, in the event that Year 1 data is insufficient to determine significance thresholds because the amount of construction was less than anticipated, the Year 2 annual report shall make these recommendations.

Report Data

Attached is the Annual report prepared by Althouse & Meade (COA 62 and ABPP Quarterly Monitoring Report by Althouse & Meade February 13, 2013).

Topaz Solar Farm
Avian and Bat Protection Plan
and
Bird Monitoring and Avoidance Plan

Fourth Quarterly/First Annual Report for 2012

This Fourth Quarterly/First Annual Report provides information pertinent to the reporting obligations regarding implementation of various tasks required by the Topaz Solar Farm Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (Althouse and Meade, Inc. June 2011). The Avian and Bat Protection Plan (ABPP) and Bird Monitoring and Avoidance Plan (BMAP) are requirements of County of San Luis Obispo Conditions of Approval (COA) 61 and 62, and were prepared in consultation with USFWS and CDFW. Section 5.5 of the ABPP/BMAP document requires quarterly and annual reports to be submitted to the County of San Luis Obispo, U.S. Fish and Wildlife Service (USFW) and the California Department of Fish and Wildlife (CDFW). This Fourth Quarterly Report has been augmented to satisfy requirements of the annual reporting obligation, and thus constitutes the first annual report for the Topaz Solar Farms ABPP/BMAP. Information provided spans the period from January 1 through December 31, 2012.

List of Tables

List of Figures

1.0 Avian and Bat Protection Plan

The ABPP monitoring program compiles general information on bird and bat interactions, injuries and mortality at the Topaz Solar Farm. During construction phases of the project this task is completed by the project biologists, as part of routine daily biological monitoring. Data reported for the Bird Monitoring and Avoidance Plan, which provides detailed information on bird use and bird mortality at the project site, is presented below in Section 2.0.

1.1 Bird Surveys

General bird surveys are conducted on and around the project site on a daily basis throughout the year by project biologists. Species lists are generated and maintained, and interesting bird observations are highlighted. A list of 113 bird species observed on and near the project site is included as Exhibit 3.

1.2 Nesting Activity

All nests and nest starts identified during the 2012 nesting season were documented. The month each nest and nest start were found are shown in Figure 1. A total of 9 bird species were documented nesting in or near the 2012 work areas (Table 1). Other species nesting in offsite mitigation lands or future project lands are not included in this tally. Burrowing owl was the only special concern species nesting on or near the project. Nesting was documented spanning the months of March through July, with fledgling burrowing owls observed into August. The peak nesting period, in terms of number of nests and number of species nesting was late April through May. The horned lark was the most abundant nesting species, with over 50 nests and nest starts identified in May 2012.

TABLE 1. 2012 NESTING DATA BY MONTH. The number of nests detected each month is listed for 9 species between March and July.

Species	March	April	May	June	July
Barn Owl	0	0	0	1	0
Burrowing Owl	1	1	1	1	1
Common Raven	1	6	2	4	2
European Starling	2	2	1	0	0
Horned Lark	0	16	51	8	0
House Finch	2	5	3	0	0
Mourning Dove	1	1	0	0	0
Western Meadowlark	0	13	2	0	0

Species	March	April	May	June	July
Say's Phoebe	1	0	0	0	0

Horned larks nest on the ground in a woven grass cup, often placed in a small depression. They prefer patchy short-grass conditions with bare spots. Array areas with newly vegetated ground provided a preferred nesting substrate. Although specific data was not compiled, our observations suggest horned lark nesting density was higher in array areas than in undisturbed grassland. Nest success was observed to be low in the array areas, with a high rate of predation by ravens and other wildlife. When a nest was predated, surveys of the vicinity often showed attempts to re-nest close by. Horned larks do not re-use nests. No prevention methods were utilized to keep horned larks from nesting in the arrays other than removal of nest starts. Detection of nest starts required intensive daily survey efforts, and nests with eggs or chicks were often found and left in place.

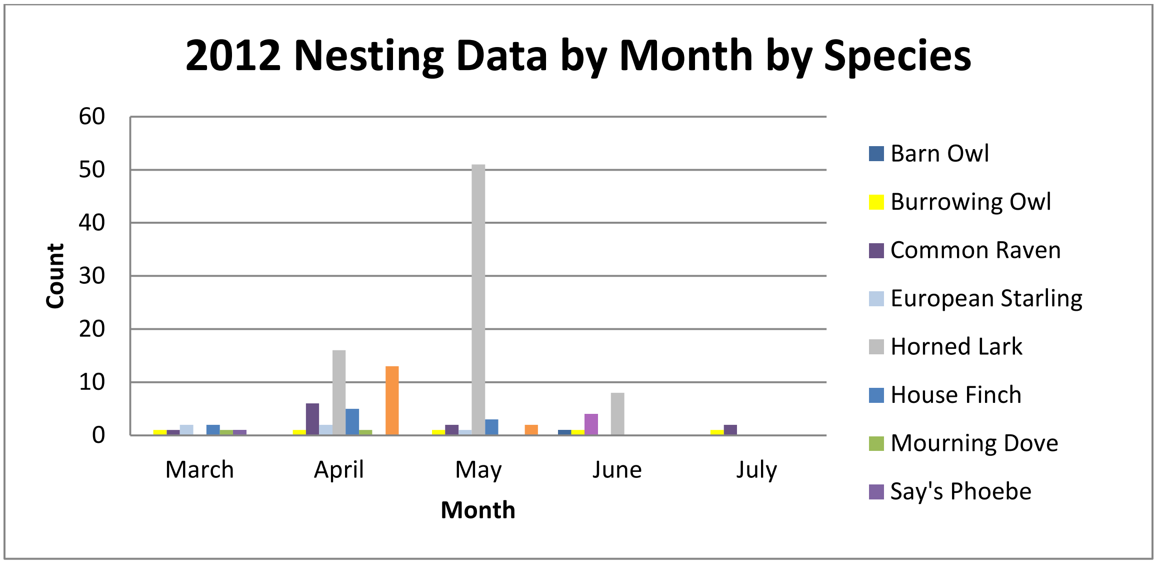
Western meadowlarks nest on the ground in taller grass habitats. All meadowlark nests identified were in future work areas containing tall grasses with abundant mustards. Mowing of tall grass fields prior to nesting activity was conducted in limited areas to prevent meadowlark nesting.

House finches nested or attempted to nest on construction equipment and materials throughout the project site. Preferred nesting areas were in small pieces of equipment, gaps in spools, and openings in cardboard boxes. Flashing tape and bird netting were used to prevent house finch nesting on materials and equipment. Both of these methods were effective.

Ravens nested on power poles within and around the project. They also attempted to nest on heavy equipment and on abandoned windmills in future work areas. Nesting materials were removed daily from some nest sites to prevent nesting. For equipment, removing nest starts and moving the equipment to a new location solved the problem. At one medium-voltage power pole within the project the nest start was removed on several occasions but eventually the ravens were allowed to nest on the pole. Unfortunately one chick died as a result of entanglement in nesting materials.

Burrowing owls nested in several locations immediately adjacent to the project. One nest attempt along Helios Way failed when one of the adults died. One nest northeast of Block 6 was observed to have 7 chicks in June 2012. Biologists observed a prairie falcon kill one of the burrowing owl chicks as it stood with the cohort at the burrow entrance. Survival of the remaining chicks was not known, but all remaining were fledged in August 2012. A third nest located west of the project successfully fledged, but the number of fledglings was not determined.

FIGURE 1. 2012 NESTING DATA BY MONTH.



1.3 Avian and other Wildlife Mortality

General biological monitoring of the Topaz work areas documented bird, bat and other wildlife mortality. All mortality identified on site from January through December 2012 is provided in Table 2. Cause of death is reported when known.

TABLE 2. BIRD AND OTHER WILDLIFE MORTALITY. Bird and other wildlife mortality detected at the Topaz Solar Farm, January through December 2012.

Species	Cause of Death	Notes
January 2012		
Horned Lark *Eremophila alpestris*	Unknown	One carcass found under powerlines along Tower Road
California Vole *Microtus californicus*	Unknown	One carcass removed from an open fence post hole
February 2012		
Mourning Dove *Zenaida macroura*	Raptor predation	One carcass found 200 yards north of Hwy 58 on Helios Way
Pacific Gopher Snake *Pituophis catenifer catenifer*	Unknown	One carcass found in grass east of Phase 1 North Array
Pacific Gopher Snake *Pituophis catenifer catenifer*	Construction activities	Hit by road grader in dust control pond area
Western Meadowlark *Sturnella neglecta*	Raptor predation	One carcass found on Tower Road
Horned Lark *Eremophila alpestris*	Predation	One carcass found in the secure laydown area
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Phase 1 North Array

Species	Cause of Death	Notes
March 2012		
Botta's Pocket Gopher *Thomomys bottae*	Unknown	One carcass found in Phase 1 South Array
Horned Lark *Eremophila alpestris*	Predation	Remains found in Phase 1 North Array
House Finch *Carpodacus mexicanus*	Predation	Three carcasses removed from the Helios laydown; house-cat is probable predator
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass found in Block 3
Savannah Sparrow *Passerculus sandwichensis*	Entanglement/Predation	One carcass caught in exclusion net and partially eaten in Helios laydown area
Heermann's Kangaroo Rat *Dipodomys heermanni*	Drowning	One carcass found in the Helios wheel wash
April 2012		
Unidentified Mice	Drowning	Two carcasses found in the Helios wheel wash
Unidentified Mice	Unknown	Two carcasses found under materials stack in Phase 1 South Array
Horned Lark *Eremophila alpestris*	Unknown	One carcass found in Phase 1 South Array
Pacific Gopher Snake *Pituophis catenifer catenifer*	Construction activities	Killed by equipment moving materials
Pacific Gopher Snake *Pituophis catenifer catenifer*	Entanglement	One carcass found in bird abatement netting in the Helios laydown area
Savannah Sparrow *Passerculus sandwichensis*	Entanglement	One carcass found in bird netting in the Helios laydown area
Botta's Pocket Gopher *Thomomys bottae*	Unknown	Two carcasses found in open fence post holes
Heermann's Kangaroo Rat *Dipodomys heermanni*	Unknown	One carcass found in open fence post hole
May 2012		
Savannah Sparrow *Passerculus sandwichensis*	Predation	Two carcasses found in Phase 1 South Array; house-cat is probable predator
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass found in trench in Phase 1 North Array
Deer Mouse *Peromyscus maniculatus*	Drowning	Two carcasses found in dust control pond well head
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Unknown	One carcass found in Phase 1 North Array
California Ground Squirrel *Spermophilus beecheyi*	Predation	One carcass found near dust control pond
California Ground Squirrel *Spermophilus beecheyi*	Predation	One carcass found in Block 3

Species	Cause of Death	Notes
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Five carcasses removed from Helios Way
Wilson's Phalarope *Phalaropus tricolor*	Unknown; either drowning or raptor predation	One carcass found in dust control pond
Northern Pacific Rattlesnake *Crotalus oreganus oreganus*	Vehicle strike	One juvenile found in Phase 1 North Array
Horned Lark *Eremophila alpestris*	Unknown	One carcass with no visible wounds on Helios Way
Horned Lark *Eremophila alpestris*	Raptor predation	One carcass found outside Block 3 fence
Horned Lark *Eremophila alpestris*	Raptor predation	One carcass found in Block 2
House Finch *Carpodacus mexicanus*	Construction activities	One egg crushed during accidental exposure of nest built in cable roll; nest subsequently abandoned
June 2012		
Horned Lark *Eremophila alpestris*	Predation	One carcass found in Phase 1 South Array
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass found in Phase 1 South Array
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass found in Block 2
House Finch *Carpodacus mexicanus*	Predation	On material stacks. Two eggs and two dead chicks. Nest abandoned.
Unidentified Mice	Drowning	Two carcasses found in dust control pond well head
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Three carcasses removed from dust control pond
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Access Road A
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	One carcass removed from Helios laydown entrance
Pacific Gopher Snake *Pituophis catenifer catenifer*	Construction activities	One killed during ground preparation work in Block 1
Pacific Gopher Snake *Pituophis catenifer catenifer*	Construction activities	Two juveniles killed during ground preparation work in Block 2
Brewer's Blackbird *Euphagus cyanocephalus*	Injury	One female flew into the side of a concrete vault
July 2012		
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Drowning	11 carcasses were removed from the dust control pond in July
Deer Mouse *Peromyscus maniculatus*	Construction activities	2 dead mice were removed from a work area, likely crushed by moving materials
Horned Lark *Eremophila alpestris*	Unknown	One carcass was removed from an array area

Species	Cause of Death	Notes
European Starling *Sturnus vulgaris*	Unknown	Carcass found near a work area perimeter fence, no apparent injuries
Western Bluebird *Sialia mexicana*	Probable vehicle strike on Highway 58 off site, carried onto site by car.	Juvenile found near cars in parking lot
Common Raven *Corvus corax*	Entanglement in nesting material	Foot of nestling was entangled in nesting material, bird died when it tried to fledge.
August 2012		
Deer Mouse *Peromyscus maniculatus*	Vehicle strike	2 carcasses were removed from project roads in August
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Five carcasses removed from dust control pond
California Ground Squirrel *Spermophilus beecheyi*	Unknown	Two carcasses were removed from work areas in August
Violet-Green Swallow *Tachycineta thalassina*	Drowning	Juvenile removed alive from dust control pond; died shortly thereafter
Horned Lark *Eremophila alpestris*	Unknown	One carcass removed from array area in Block 2
Desert Cottontail *Sylvilagus auduboni*	Abandoned by parents	3 juveniles found under a pallet, two were relocated, third was dead
Cooper's Hawk *Accipiter cooperii*	Unknown	Desiccated carcass found in arrays of Block 6. CDFG and USFWS notified. Carcass was transferred to CDFG Jan 10, 2013.
September 2012		
Virginia Rail *Rallus limicola*	Collision with fence	Rail collected dead in parking area at base of chain link fence with obvious collision wound
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Two carcasses were removed from the dust control pond in September
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Two carcasses removed from work area in Block 5
Brewer's Blackbird *Euphagus cyanocephalus*	Unknown; possible entrapment or crushing by moving materials	Four carcasses were removed from between materials boxes in a laydown yard.
Botta's Pocket Gopher *Thomomys bottae*	Unknown; possible failed predation attempt	One carcass was removed from Block 1
Deer Mouse *Peromyscus maniculatus*	Crushed by materials	Reported by workers, mouse died before it could be treated or released
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass removed from Block 5
Heermann's Kangaroo Rat *Dipodomys heermanii*	Equipment strike	Mortally wounded by heavy equipment
Horned Lark *Eremophila alpestris*	Raptor predation	Reportedly dropped by a raptor, the carcass was removed by biologists
Horned Lark *Eremophila alpestris*	Raptor predation	One carcass with injuries consistent with a failed raptor predation attempt was removed from Block 8

Species	Cause of Death	Notes
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle/equipment strike	2 juvenile gopher snake carcasses were removed from work areas
Desert Cottontail *Sylvilagus audubonii*	Exposure	A juvenile rabbit was removed alive from a trench but died shortly thereafter
Common Raven *Corvus corax*	Unknown	One carcass was removed from Block 1 work area with no apparent injuries
October 2012		
Common Raven *Corvus corax*	Predation	Remains were found in Block 5
Long-billed Curlew *Numenius americanus*	Predation	Carcass found with missing head in trench in Block 1
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle/equipment strike	Mortally wounded on a project road south of Block 4; euthanized by biologists
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Mortally wounded by a forklift in Block 2; euthanized by biologists
Horned Lark *Eremophila alpestris*	Unknown	Carcass removed from Access Road B; no visible injuries present
November 2012		
Horned Lark *Eremophila alpestris*	Unknown	Carcass found in Block 5
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Juvenile found dead on Access Road B
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Killed by ground-breaking equipment in Block 8 East
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Killed by a trencher in Block 4
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Carcass found on Helios Way
Deer Mouse *Peromyscus maniculatus*	Unknown	Juvenile found dead outside of nest in materials box
Pacific Chorus Frog *Pseudacris regilla*	Equipment strike	One frog euthanized due to injuries from heavy equipment at the Cochrane site
Coyote *Canis latrans*	Unknown	Old carcass observed under debris pile at the Cochrane site
Barn Owl *Tyto alba*	Drowning/Entrapment	Old carcass observed at bottom of well at the Cochrane site
Western Meadowlark *Sturnella neglecta*	Drowning/Entrapment	Old carcass observed at bottom of well at the Cochrane site. Pre-dates project start.
Western Meadowlark *Sturnella neglecta*	Predation	Carcass found in Block 9 West
Desert Cottontail *Sylvilagus audubonii*	Unknown	Carcass found under panels in Block 2
December 2012		

Species	Cause of Death	Notes
Unidentified Mice	Entrapment	Two mice found in backfilled vault
Mourning Dove *Zenaida macroura*	Raptor predation	One carcass removed from surface of module in Block 7. Presumably dropped by raptor.
Mourning Dove *Zenaida macroura*	Predation	One headless carcass removed from the Cochrane site
Horned Lark *Eremophila alpestris*	Predation	One headless carcass removed from Block 1
House Finch *Carpodacus mexicanus*	Unknown	One carcass removed from Block 3
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Equipment strike	One carcass removed from Block 8
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Two snakes killed by heavy equipment at the Cochrane site
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	One carcass removed from Block 9
Western Meadowlark *Sturnella neglecta*	Injury	One carcass removed from Access Road B; bird appears to have flown into a moving vehicle
California King Snake *Lampropeltis getula californiae*	Equipment strike	One carcass removed from Block 9
Desert Cottontail *Sylvilagus auduboni*	Equipment strike	Three carcasses removed from the Cochrane site
Heermann's Kangaroo Rat *Dipodomys heermanni*	Unknown	One carcass found in open fence post hole in Block 8 West
Pacific Chorus Frog *Pseudacris regilla*	Unknown	One carcass removed from a pitfall trap at the Cochrane site

2.0 Bird Monitoring and Avoidance Plan

The BMAP study utilizes avian use surveys and avian fatality surveys to produce a risk index for various project components deemed to be potentially dangerous to birds, including array areas, overhead power lines and energized equipment (substation). Offsite grassland areas were used as reference sites to compare Bird Utilization Rates, Bird Fatality Rates, and ultimately Bird Risk Index. The BMAP study has two primary goals:

Goal 1. Provide Project owners/managers with scientifically-based risk analyses to facilitate implementation of Adaptive Management actions to minimize conflicts between Project components and birds.

Goal 2. Provide a rigorous scientific study of avian use and mortality associated with specific components of an industrial scale photovoltaic solar facility that can be used by wildlife regulators as a planning tool for future solar projects.

To accomplish these goals, the BMAP outlines five Objectives with specific Tasks:

Objective 1. Assess changes in total bird abundance, species composition, and species richness relative to development and operation of the Project compared to undeveloped reference sites;

Task 1.1: Implement Avian Use Surveys.

Task 1.2: Submit quarterly and annual monitoring reports.

Objective 2. Calculate Bird Utilization Rate, Bird Fatality Rate, and Bird Risk Index for three specific Project components (Array Areas, Overhead Power Lines, Substation/Switching Station);

Task 2.1: Implement Avian Fatality Monitoring Surveys, Searcher Efficiency Trials, and Scavenger/Carcass Removal Trials.

Task 2.2: Run calculations on survey data according to methods in Section 5.4.

Task 2.3: Submit quarterly and annual monitoring reports.

Objective 3. Conduct risk assessment analyses for each Project component based on calculated Bird Utilization Rate, Bird Fatality Rate, and Bird Risk Index;

Task 3.1: Prepare a written analysis of survey data and calculated Bird Risk Index for each Project component to be included in the annual report.

Objective 4. Inform TSF facility managers of Adaptive Management requirements when Bird Risk Index and/or Bird Fatality Rate indicates significance thresholds for avian mortality have been reached (refer to Section 6.0);

Task 4.1: Submit quarterly and annual monitoring reports.

Objective 5. Prepare a scientific paper describing the results of avian use surveys and avian fatality monitoring surveys, and the conclusion regarding the risk level that the Project poses for avian resources.

Task 5.1: Within one year of completion of the study data collection, prepare and submit a scientific paper to the County of San Luis Obispo.

2.1 Discussion regarding Year 1 Data

This Fourth Quarterly/First Annual Report of the ABPP/BMAP provides preliminary data collected for Objectives 1, 2 and 3 (Sections 2.2, 2.3 and 2.5, below). The data is considered preliminary for Year 1 since the pace of construction did not facilitate a large number of Avian Use Surveys or Avian Fatality Surveys to be completed in Array Area, Overhead Powerline and Energized Equipment survey areas, as these areas were not completed with construction until late in the year.

When the BMAP study design was prepared in 2010, prior to start of construction, it was assumed that more completed array areas and powerlines would be available earlier in the year for avian surveys. Therefore, the Year 1 annual report was the designated timeframe for establishing significance thresholds on avian mortality levels. The significance thresholds are to be determined in consultation with the U.S. Fish and Wildlife Service, California Department of Fish and Wildlife, and the County of San Luis Obispo, based on Bird Risk Index data.

We propose to modify the significance threshold determination schedule as presented in the BMAP so that data may be collected through 2013 on avian use and avian fatality at project components. Another year of data from completed project components will provide a robust foundation for the Bird Risk Index calculations, which will better inform significance determinations. If this approach is acceptable to the reviewing agencies, the Topaz Solar Farm ABPP/BMAP document will be revised and resubmitted to reflect the changes.

With respect to the proposal to postpose the significance threshold determination, Objective 4 will be reported beginning with the first quarterly report for Year 2, after significance thresholds have been determined. Objective 5 will be completed within one year after completion of the field surveys.

2.2 Avian Use Surveys

Avian Use Surveys commenced in November 2011, prior to the start of construction, to gather baseline data on bird use in the project area. Avian Use Surveys will inform the Bird Utilization Rate calculations (see Section 2.2.1, below). Construction commenced in late November 2011 in a limited footprint, and slowly expanded in area throughout 2012. Avian use surveys were conducted monthly from November 2011 through December 2012, and will continue throughout the construction period and for three years after construction is complete. Each month, 63 randomly selected survey points were completed, for a total of 882 survey points completed as of December 2012. The 63 survey points include 31 inside existing or future array areas, 18 along existing or future overhead power lines, 10 in grassland reference sites and 4 at the substation. At each point, a 10 minute bird use count is conducted within a 50 meter radius of the surveyor.

Avian Use Survey points were selected each month across all six phases of the project and in offsite grassland reference areas (Exhibit 1). Each month, as construction area increased in size, more of the survey points occurred in developed area. Those points located within future project areas that had not been developed at the time of the survey are categorized as Baseline. Baseline condition is similar to Reference site condition in that it is not developed, however it differs in being cropland habitat versus grassland habitat. Therefore, comparison of Baseline with Reference data could provide information regarding Bird Utilization Rate in different habitat types, if desired.

Forty-three bird species were detected during the avian use surveys from November 2011 through December 2012. Thirteen of these species were detected only once. Horned lark was overwhelmingly the most commonly detected species (6848 detections), followed by house finch (1416), savannah sparrow (776), long-billed curlew (604), common raven (565) and mountain bluebird (526).

For reasons outlined above in Section 2.1, the data collected for Avian Use Surveys and the subsequent analyses for Objective 1 are considered preliminary. Sections 2.2.1, 2.2.2 and 2.2.3 outline our preliminary data collected for bird abundance, species composition and species richness.

2.2.1 Preliminary bird abundance

Total bird abundance is compared in Table 3 between Array Area, Overhead Powerline, Energized Equipment, Reference Site and Baseline survey area categories. Bird abundance is calculated as average number of birds observed per Observation Point. Highest bird abundance was for the Baseline category, at 15.85 birds per Observation Point. The Baseline category represents crop stubble fields prior to start of construction. Reference Sites consisting of grassland habitat had an average of 12.19 birds per Observation Point. Completed Array Areas averaged 11.09 birds per Observation Point, Overhead Powerlines averaged 7.95 birds and Energized Equipment averaged 7.0 birds. Preliminary data suggest a reduction in total bird abundance between the Baseline category and the completed Array Area category.

TABLE 3. PRELIMINARY BIRD ABUNDANCE COMPARISON.

Survey Area Category	**Bird Abundance** **(Average # Birds/Observation Point)**
Baseline (Crop Stubble)	15.85
Reference Site (Grassland)	12.19
Overhead Powerline	7.95
Energized Equipment	7.00
Array Area	11.09

2.2.2 Preliminary species richness

Species richness is a measure of the number of different species in a given area. Table 4 lists the total number of species observed within each of the five survey area categories. Baseline Observation Points had 33 species detected, the highest of any of the survey area categories. Grassland Reference Site points had 20 species detected, both Overhead Powerline and Array Area points had 18 species detected, and Energized Equipment had 14 species.

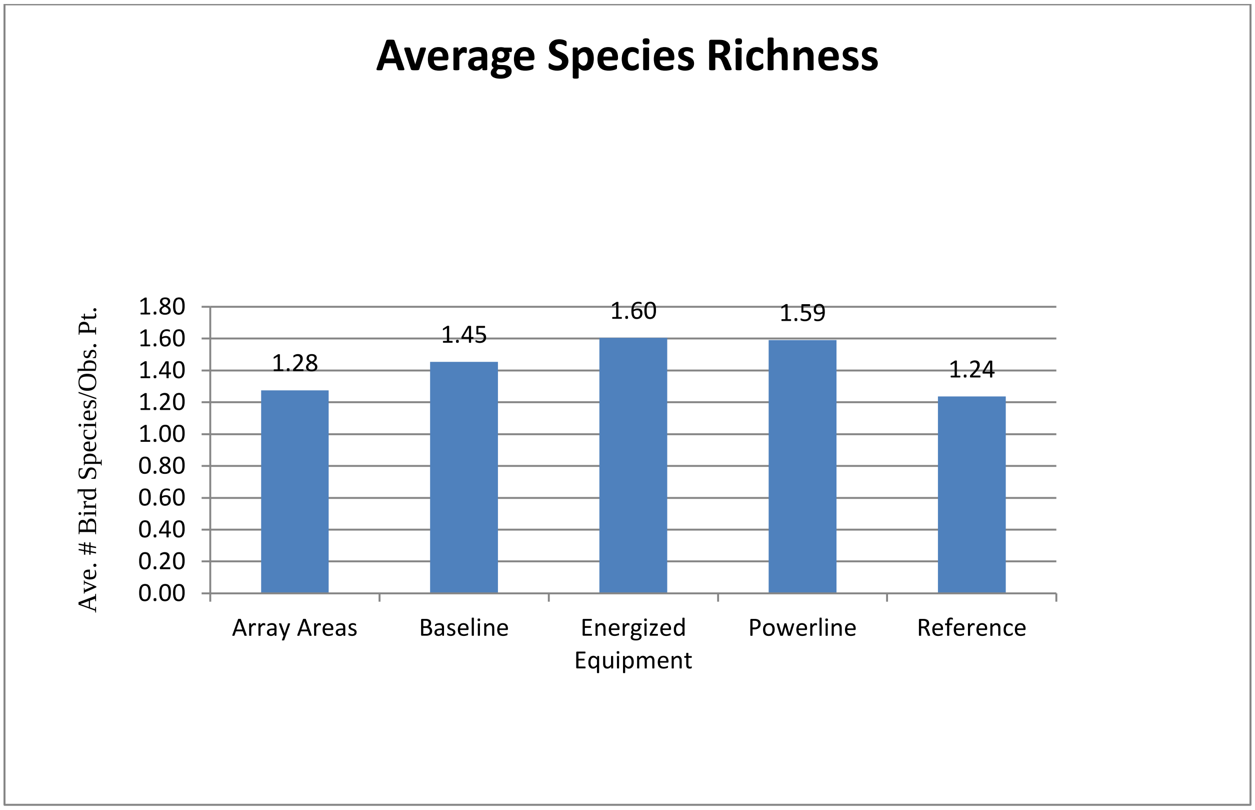
We also compared avian species richness averaged across all Observation Points in each of the five survey area categories from November 2011 through December 2012 (Table 4 and Figure 2). Species richness is markedly similar in each category. Energized Equipment and Overhead Powerlines averaged 1.60 and 1.59 bird species per Observation Point, respectively. Array Areas averaged 1.28 bird species per Observation Point, Baseline averaged 1.45 species and grassland Reference Sites averaged 1.24 species.

Preliminary data suggest a reduction in species richness between the Baseline category and the completed Array Area category.

TABLE 4. PRELIMINARY SPECIES RICHNESS COMPARISON.

Survey Area Category	Ave No. Species per Obs. Point	Total Number of Species
Baseline	**1.45**	**33**
Reference Site	**1.24**	**20**
Overhead Powerline	**1.59**	**18**
Energized Equipment	**1.60**	**14**
Array Area	**1.28**	**18**

FIGURE 2. AVERAGE SPECIES RICHNESS.



2.2.3 Preliminary species composition

Species composition refers to the relative abundance of different species in a given area. For each species we calculated the average number of birds detected for Observation Points within each of the five survey area categories (Table 5). We looked at the 6 most abundant species detected from November 2011 through December 2012: horned lark, house finch, savanna sparrow, long-billed curlew, common raven and mountain bluebird.

Of the 6 most abundant species detected, the Baseline and Reference Site categories detected all 6 species, or 100%. Both of these categories represent non-developed habitat. Overhead Powerline and Energized Equipment categories detected 5 of the 6 most abundant species (83%). Completed Array Areas detected only 4 of the 6 most abundant species, or 67% (Table 5).

TABLE 5. PRELIMINARY SPECIES COMPOSITION COMPARISON. Average number of individuals is listed for each of the 6 species within the five survey area categories. Percent of top 6 species is listed at far right.

Survey Area Category	Horned Lark Ave #	House Finch Ave #	Savanna Sparrow Ave #	Long-billed Curlew Ave #	Common Raven Ave #	Mountain Bluebird Ave #	% of Top 6 Species Recorded
Baseline	3.11	0.57	0.39	0.35	0.32	0.19	**100%**
Reference Site	2.32	1.04	0.14	0.17	0.18	0.67	**100%**
Overhead Powerline	1.72	0.35	0.34	0.00	0.02	0.01	**83%**
Energized Equipment	1.33	0.60	0.28	0.00	0.02	0.02	**83%**
Array Area	3.80	0.11	0.02	0.00	0.01	0.00	**67%**

2.2.4 2012 Bird Utilization Rate Calculations

Bird Utilization Rate (BUR) is calculated as the number of unique bird observations divided by the number of observation point counts. Each month 63 observation point counts are randomly chosen and surveyed for 10 minutes each. A unique bird observation is recorded each time a bird or group of birds enters the survey area.

We calculated Bird Utilization Rate for five survey area types: Array Areas, Overhead Powerlines, Energized Equipment (Substation), Reference Site (grassland) and Baseline (future work area, cropland or grassland). Where an Array Area, Overhead Powerline, or Energized Equipment survey point was conducted prior to construction commencement at that location, that point was categorized as a Baseline site since no construction activities or project facilities were present.

Average BUR for each survey area type was calculated for 2012 (Figure 3 and Table 6). Reference sites had the highest BUR, at 4.82. Array Areas were second highest, with an average BUR 3.66, and Baseline, Overhead Powerline and Energized Equipment were roughly similar with BUR of 2.97, 2.96 and 2.83 respectively.

Bird Utilization Rates were also calculated and graphed by month, for each of the five survey area types (Figure 4). Note that surveys in November and December 2011 did not include all survey area types since construction had not commenced.

FIGURE 3. 2012 AVERAGE BUR FOR ALL SURVEY AREA TYPES.

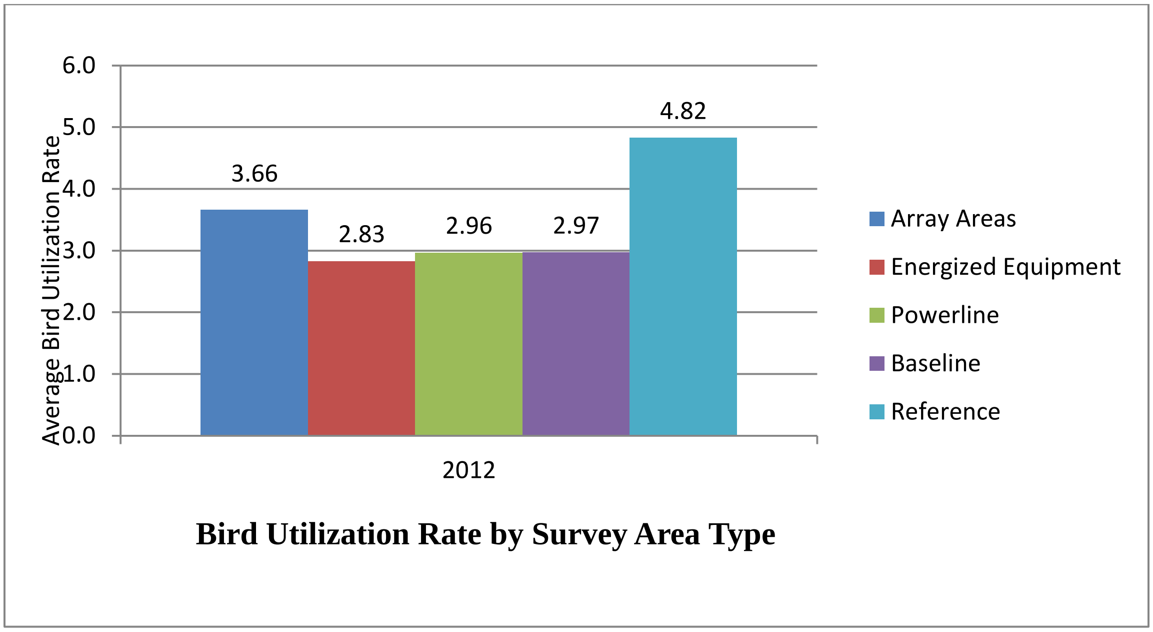


TABLE 6. BIRD UTILIZATION RATE BY SURVEY AREA TYPE. BUR is provided for each of the survey area types by month. Total monthly average BUR is provided in the last column, and average BUR for the year 2012 is provided at the bottom.

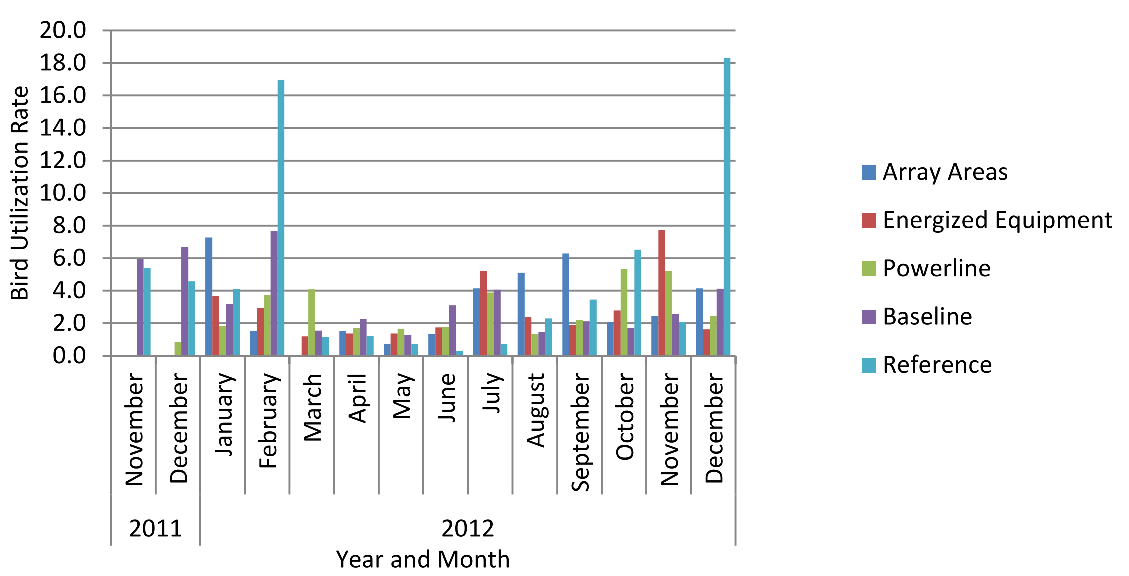
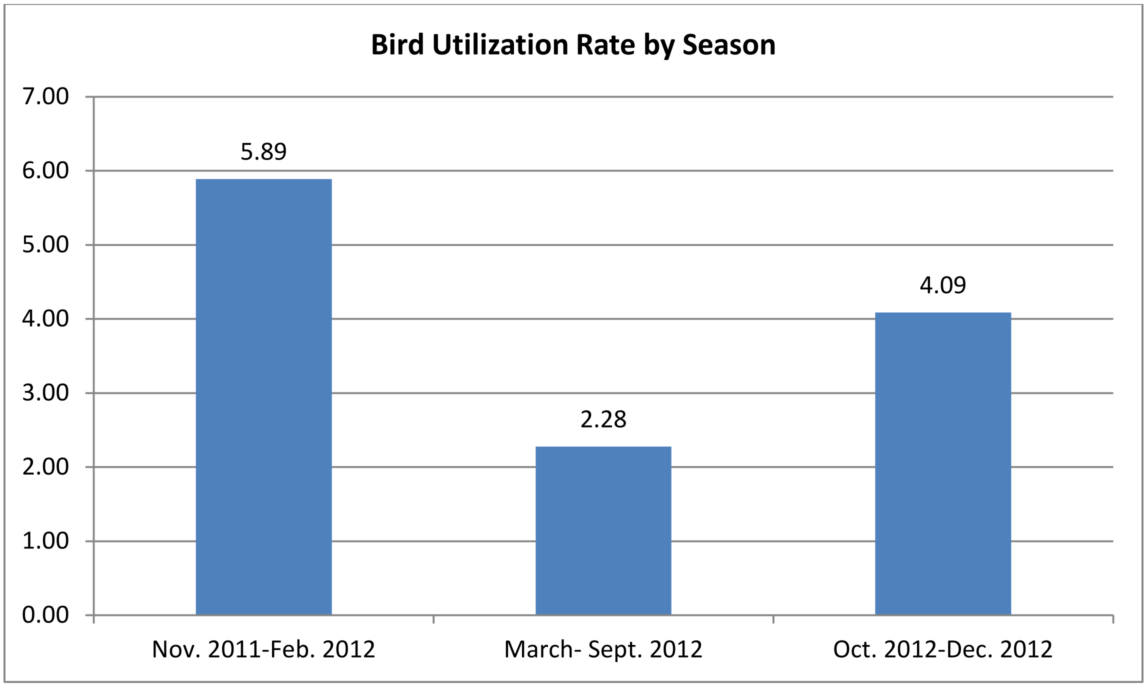
Year/Month	Array Areas	Energized Equipment	Overhead Powerline	Baseline	Reference	Average
2011 November	n/a	5.96	5.38	5.86	n/a	5.96
2011 December	0.83	6.71	4.59	6.09	0.83	6.71
2012 January	7.28	3.68	1.83	3.19	4.11	3.28
2012 February	1.50	2.92	3.75	7.67	16.98	8.31
2012 March	0.00	1.19	4.08	1.55	1.15	1.68
2012 April	1.50	1.38	1.70	2.26	1.21	1.97
2012 May	0.75	1.38	1.67	1.30	0.75	1.25
2012 June	1.33	1.75	1.79	3.11	0.30	2.30
2012 July	4.14	5.21	3.89	4.07	0.72	3.59
2012 August	5.10	2.38	1.33	1.47	2.30	2.22
2012 September	6.29	1.88	2.20	2.11	3.46	2.92
2012 October	2.08	2.79	5.35	1.72	6.53	3.18
2012 November	2.43	7.75	5.22	2.57	2.08	3.17
2012 December	4.15	1.63	2.44	4.12	18.30	5.90
Average of 2012 Monthly Surveys	**3.66**	**2.83**	**2.96**	**2.97**	**4.82**	**3.32**

FIGURE 4. MONTHLY BIRD UTILIZATION RATE. The Bird Utilization Rate is indicated for each of the five survey area types during each month from November 2011 through December 2012.



Bird Utilization Rate indicates highest general bird use during the winter period from October through February, with average BUR from November 2011 to February 2012 of 5.89 and an average BUR of 4.09 from October 2012 to December 2012. By comparison, the non-winter period spanning March to September 2012 had an average BUR of 2.28 (Figure 5). This is generally consistent with the influx of wintering birds which gather in large flocks in the Carrizo Plain during this time. Based on these preliminary results we would expect the risk of bird mortality to be higher during the winter period, if all other variables remain the same, simply due to the higher number of birds present.

FIGURE 5. BIRD UTILIZATION RATE BY SEASON. Average BUR is graphed for winter and non-winter periods.



2.3 Avian Fatality Surveys

Avian Fatality Surveys commenced upon completion of the first project components. Avian Fatality Surveys are conducted at randomly selected locations within four different survey area types: Array Areas, Overhead Powerlines, Energized Equipment (Substation) and at Reference sites[1]. Each survey area type was divided into 500 foot by 15 foot search plots. Search plots are randomly selected using an ArcGIS random point generator having defined areas as the constraining polygon. Avian Fatality Surveys are conducted within the same search plots each day for seven consecutive days every month. Repetitive surveys increase the chance of finding fatalities in a given area before predators remove the carcass. Exhibit 2 depicts the search plots covered by Avian Fatality Surveys in 2012.

During the period of July 1 through September 31, 2012 we conducted test fatality surveys at various locations during construction phases; however, no formal surveys were conducted due to incomplete project components. We used these preliminary results to guide our survey efforts in the Array Areas starting in October 2012.

In October 2012 we completed walking Avian Fatality Surveys at 168 five hundred foot transects within completed Array Area search plots, for 7 consecutive days each, totaling 1,176 search plots (111.4 linear miles, 207.3 acres) for the month. No avian fatalities

---

[1] Select Array Areas were completed and safe to conduct surveys by October 2012. The first Overhead Powerline areas were completed by the December survey. Energized Equipment areas were not complete with construction in 2012 and were therefore not surveyed.

were detected during the October survey (Table 7). Since Overhead Powerline and Substation construction were not complete, no search plots in these survey area types were conducted. We consider the October 2012 Array Area data to be a test to determine labor hours required per search plot, therefore no Reference Site search plots were conducted for comparison. This data is not included in the 4th quarter Average Fatality Rate calculation provided in Table 7, last row.

In November 2012 we completed walking avian fatality surveys at 84 five hundred foot transects within completed Array Area search plots, for 7 consecutive days each, totaling 588 search plots (55.7 linear miles, 103.7 acres). A total of 84 Grassland Reference Site search plots were completed, for 7 consecutive days each, totaling 55.7 linear miles (101.8 acres). One bird fatality was detected in the Array Area search plots and four fatalities were detected in the Reference Site search plots. The Array Area fatality was a very old mourning dove feather pile in which the cause of death could not be determined. The fatalities recorded in the Reference Site search plots consisted of two American kestrels, one domestic chicken, and one unidentified species. Each of these fatalities consisted of feather piles, and in one case (the unidentified species), a bone fragment. Cause of death could not be determined for any of the fatalities, however predation was presumed to be the likely cause for each.

In December 2012 we completed walking Avian Fatality Surveys at 126 five hundred foot transects within completed Array Area search plots, for 7 consecutive days each, totaling 882 search plots (83.5 linear miles, 155.5 acres). Powerline search plots included 3 five hundred foot transects, surveyed for 7 consecutive days each, totaling 2.0 linear miles (3.6 acres). A total of 12 grassland Reference Site search plots were completed, for 7 consecutive days each, totaling 84 linear miles (152.7 acres). One fatality was recorded in the Array Area search plots. The fatality was a domestic chicken in which only feathers were found. The cause of death was determined to be predation. No fatalities were recorded in the Powerline or Reference Site search plots.

2.3.1 2012 Bird Fatality Rate Calculations

Bird Fatality Rate (BFR) is calculated for three of the four survey area types as the number of unique bird carcasses detected divided by the number of plots searched (Table 7). Energized Equipment (Substation) was not completed in 2012 and was therefore not surveyed. The highest 4th Quarter (November and December 2012) BFR was recorded for the Reference Site search plots (0.003). The Array Area search plots had a BFR of 0.001. No bird fatalities were recorded in the Overhead Powerline search plots, so the BFR is zero.

TABLE 7. BIRD FATALITY RATE DATA.

2012 Data	**Array Areas**	**Energized Equipment**	**Overhead Powerline**	**Reference (Grassland)**
Number of Search Plots				
October Search Plots	**1,176**	**0**	**0**	**0**
November Search Plots	**588**	**0**	**0**	**591**
December Search Plots	**882**	**0**	**21**	**887**

2012 Data	**Array Areas**	**Energized Equipment**	**Overhead Powerline**	**Reference (Grassland)**
Number of Bird Fatalities				
October Bird Fatalities	**0**	--	--	--
November Bird Fatalities	**1**	--	--	**4**
December Bird Fatalities	**1**	--	**0**	**0**
Bird Fatality Rate (No. Fatalities/No. Search Plots)				
October Bird Fatality Rate	**0**	--	--	--
November Bird Fatality Rate	**0.002**	--	--	**0.007**
December Bird Fatality Rate	**0.001**	--	**0**	**0**
4th Quarter Average Fatality Rate (Nov. & Dec data)	**0.001**	--	**0**	**0.003**

2.4 Scavenger Trials and Searcher Efficiency Trials

Scavenger trials and searcher efficiency trials are proposed to determine any bias in the fatality survey results. These trials will not commence until construction is complete in designated project component areas[2].

2.5 Preliminary Bird Risk Index Calculations

Bird Risk Index (BRI) is calculated in order to quantify multiple measures into a single number to facilitate comparison of the different survey area types and to monitor for trends over time. For this BMAP study, BRI is calculated as the Bird Fatality Rate divided by the Bird Use Rate (Table 8). We are providing a preliminary BRI for each survey area type in this first annual report, but acknowledge that insufficient fatality surveys were completed in 2012 to provide a strong conclusion. Significance thresholds should not be based on these preliminary results.

The offsite grassland Reference Site search plots had a Bird Risk Index double that of the Array Area search plots. Bird fatality detections were extremely low in both the Array Area and Reference Site search plots. No bird fatalities were detected in the Overhead Powerline search plots, however we surveyed significantly fewer search plots within this survey area type compared with Array Areas and Reference Sites.

---

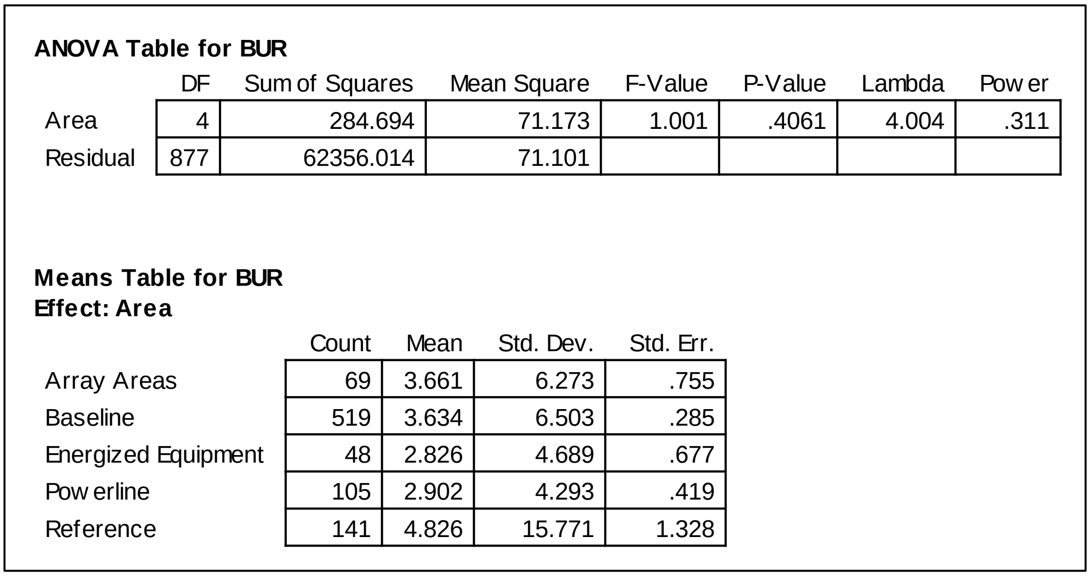
[2] Scavenger trials and searcher efficiency trials commenced in February 2013.

TABLE 8. PRELIMINARY BIRD RISK INDEX. BUR, BFR and BRI are provided for the Array Area, Overhead Powerline, Energized Equipment and Reference Site search plots.

Survey Area Type	Bird Utilization Rate (BUR)	Bird Fatality Rate (BFR)	Bird Risk Index (BRI)
Array Area	3.66	0.001	0.0003
Overhead Powerline	2.96	0	0
Energized Equipment	2.83	n/a	n/a
Reference Site	4.82	0.003	0.0006

Statistical analysis of the BUR found no difference among treatment types (areas) across the study area. This is due to the large variation in the bird observation point data results (Table 9).

TABLE 9. BUR STATISTICAL ANALYSIS.



ANOVA Table for BUR

	DF	Sum of Squares	Mean Square	F-Value	P-Value	Lambda	Power
Area	4	284.694	71.173	1.001	.4061	4.004	.311
Residual	877	62356.014	71.101				

Means Table for BUR
Effect: Area

	Count	Mean	Std. Dev.	Std. Err.
Array Areas	69	3.661	6.273	.755
Baseline	519	3.634	6.503	.285
Energized Equipment	48	2.826	4.689	.677
Powerline	105	2.902	4.293	.419
Reference	141	4.826	15.771	1.328

3.0 Discussion

Avian Use Surveys were conducted for all 12 months of 2012. A total of 63 observation points were surveyed each month, for a total of 756 for the year. For observation points in Array Areas where panels were installed, observer visibility was limited. This effect could potentially reduce the number of unique bird detections per observation point compared with open Reference Site observation points. Although we anticipated this effect, we are concerned that the severity of the sight limitation may be worse than anticipated. Therefore we decided to change the parameters of our random selection criteria for 2013 so that observation points for the Array Areas only fall on interior north-south oriented access roads. This selection criterion will only choose observation points that allow visibility to the 50 meter survey area extent to the north and south along the narrow access road, as well as to the east and west down the panel rows, while still collecting data on bird use within the Array Areas.

A total of 250.6 linear miles of 15-foot wide Avian Fatality Survey search plots were systematically surveyed on foot by project biologists within completed Array Areas; two bird fatalities were recorded. One fatality was a domestic chicken that was obviously brought to the location by a predator. The other fatality was an old mourning dove feather pile that suggested raptor predation; however cause of death was recorded as unknown. Grassland Reference Site search plots covered a total of 139.7 linear miles of 15-foot wide search plots. Four fatalities were recorded in the Reference Site search plots. Cause of death could not be determined for any of these fatalities, however predation was presumed to be the likely cause for all. General fatality rates appear to be very low in work areas (1 fatality every 125 miles of array rows).

Searcher efficiency trials and scavenger/carcass removal trials will be conducted in 2013 to provide insight into the accuracy of Avian Fatality Survey data. Results of these trials will be reported in the first quarterly report for 2013, and the second annual report will include Fatality Survey data adjusted to account for the results of the trials.

Annual Report

COA 62 Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan

March 12, 2014

Discussion

This report has been prepared to address the reporting requirements for Condition of Approval (COA) 62 Bird Monitoring and Avoidance Plan (BMAP). The BMAP report was prepared to include bats and the title revised to the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP).

In response to COA 62, the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP) has been prepared, which further describes the approach to implementing the condition requirements.

COA 62 requires quarterly and annual reports. Following the completion of the fourth quarter of monitoring the biologist shall prepare an annual report that summarizes the year's data, analyzes any project-related bird fatalities or injuries detected, and provides recommendations (in consultation with the County) for future monitoring and any adaptive management actions needed.

Annual Reportable Items

COA 62 BMAP requires specific significance thresholds that would trigger Adaptive Management will be defined in the Year 1 annual report based on analysis of the Year 1 data, in consultation with the County, CDFW and USFWS. Significance thresholds will be based on statistical comparison of Project Site data and offsite reference plot data. Comparison with reference plots will provide insight regarding the significance of any detected fatalities, so that thresholds can be assigned with confidence. If, in the event that Year 1 data is insufficient to determine significance thresholds because the amount of construction was less than anticipated, the Year 2 annual report shall make these recommendations.

Report Data

Attached is the Annual report prepared by Althouse & Meade (COA 62 and ABPP Quarterly Monitoring Report by Althouse & Meade March 12, 2014).

1.0 Introduction

This Fourth Quarter/Second Annual Report (Report) provides information specific to reporting obligations for implementation of tasks required by the Topaz Solar Farms Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (Althouse and Meade, Inc. June 2011). The Avian and Bat Protection Plan (ABPP) and Bird Monitoring and Avoidance Plan (BMAP) are requirements of County of San Luis Obispo (County) Conditions of Approval (COA) 61 and 62, and were prepared in consultation with the U.S. Fish and Wildlife Service (USFWS) and the California Department of Fish and Wildlife (CDFW). They were combined to form the ABPP/BMAP document. Section 5.5 of the ABPP/BMAP document requires quarterly and annual reports to be submitted to the County, USFW, and CDFW. This Report is prepared to satisfy requirements of the annual reporting obligation, and thus constitutes the second annual report for the Topaz Solar Farms ABPP/BMAP. Information provided spans the period from January 1 through December 31, 2013.

Construction at Topaz Solar Farms began on December 5, 2011. As of December 31, 2013, work had occurred in Phases 1 through 6 of the project. Construction activities included but were not limited to grading and leveling land; creating roads; installing posts, rails, and photovoltaic panels; installing overhead and underground electrical lines; installing two stream crossings consisting of articulated concrete blankets; erecting San Joaquin kit fox friendly fencing around solar arrays; installing artificial burrowing owl dens and kit fox escape dens; and removal of unneeded barbed wire fencing. As of December 31, 2013, construction was complete in Blocks 1 through 9 (Exhibit 1). These Blocks were turned over to Operations and Maintenance (O&M) in 2013. Construction was still occurring on Blocks 10 through 18, and had not begun on Blocks 19 through 22. Blocks under construction during 2013 are anticipated to be completed in 2014.

2.0 Avian and Bat Protection Plan

The ABPP monitoring program compiles general information on bird and bat interactions, injuries, and mortality at Topaz Solar Farms (TSF). During construction phases of the project, this task is completed by the project biologists as part of routine daily biological monitoring. Data reported for the Bird Monitoring and Avoidance Plan, which provides detailed information on bird use and bird mortality at the project site to inform a bird risk analysis, is presented below in Section 3.0. Abbreviations that are used throughout this document are listed on page iv.

2.1 Bird Surveys

General bird surveys are conducted on and around the TSF project site on a daily basis throughout the year by project biologists. Lists of bird species observed by each biological monitor are written on daily construction survey forms, which are then scanned, archived, and reviewed by project ornithologists Peter Gaede and Jason Dart. A cumulative list is then generated by the project ornithologists and updated throughout the year. An annotated list of the 139 species recorded at the TSF project site since 2011 is included as Appendix C, which includes information on seasonal occurrence, status within the greater Carrizo Plain region, and 2013 breeding status. Structured Avian Use Surveys are conducted monthly as part of the

BMAP to gather data on bird use within and near the TSF project. These surveys and results are discussed in Section 3.1.

2.1.1 Waterbird observations

Waterbirds are defined here as birds that are predominantly associated with water. This includes a diverse group of species that are ecologically tied to water, for at least part of their lives. The non-passerine groups of waterbirds that have been recorded at Topaz Solar Farms include waterfowl (geese and ducks, Photo 1), grebes (Photo 2), egrets, herons, ibis, osprey, eagle (Photo 3), rails, coots, avocet, stilt, plovers, shorebirds, and gulls. Most of these species are spring/fall migrants and/or winter visitors to the region. A total of 36 waterbird species and 5 unidentified waterbirds have been observed at the TSF project site (TABLE 1).

Documentation of waterbirds occurring at TSF have been made since the beginning of project construction in an effort to address the question of whether the reflective nature of installed photovoltaic array panels can potentially appear as bodies of water when viewed from the air. Most of the waterbirds documented at the site have been found at a temporary dust control pond (DCP), which was built on site during the initial phases of construction. Although small in size (approximately 415 by 120 feet), this body of water represents a very visible attractant to birds that associate with water in an otherwise dry environment, and is similar in size to many other human-made ponds in the area.

The diversity of waterbird species observed at TSF increased in 2013. A total of 34 species were recorded in 2013 compared with 23 species in 2012. The majority of waterfowl observed at the TSF site were at the DCP or were fly-over observations. Duration of presence at the DCP was generally for only a very short period of time (typically less than one day), as no food is available. Data is not available to support any conclusions for why the waterbirds came into the project area, whether due to the presence of the DCP itself or due to the panels appearing like water from the air. A green-winged teal was found standing on the ground in the Block 11 arrays (see Photo 4 below) in 2013, and there were two observations of American coot walking in the arrays. In fall 2013 flocks of shorebirds flew up from the ground in array areas (a flock of 20 Western sandpipers and 53 small, unidentified shorebirds in Block 3 on August 20; and a flock of Western sandpipers in Block 11 on October 7). Sora and Virginia rail are both small, secretive birds generally associated with freshwater marshes. Both species are migratory and winter south of the Carrizo region; the birds found at the project site in 2013 were both juvenile fall migrants. The two records for this group in 2013 include a Virginia rail found exhausted under panels in Block 11 on September 9 and a sora found dead on Helios Way on October 8 with no visible injuries. Herons, egrets, and ibis were observed at the site primarily in spring and fall. All members of the waterfowl group (great blue heron, great egret, snowy egret, green heron, and white-faced ibis) are considered uncommon to rare on the Carrizo Plain, and observations of these species are considered noteworthy. Most were observed flying over the arrays or briefly visiting the DCP. One individual, a great blue heron, was observed perched on a module table in Block 8.

Osprey and bald eagle are raptors that typically nest near large bodies of water, and in the case of the former, feed exclusively on fish. Both of these species were observed at the project site seasonally before and during construction. A bald eagle (see Photo 3 below) was observed flying over the project site in winter 2012/13 and again in winter 2013/2014, and was occasionally seen on the ground (presumably hunting) in nearby fields. Most of the shorebirds observed at the site are long-distance migrants that travel through the area in spring and fall. Given the dry conditions in 2013 and the overall lack of suitable stop-over habitat in the region, it is not surprising that birds were seen in greater numbers at the DCP.

TABLE 1. 2012-2013 WATERBIRD OBSERVATIONS. Listed are 41 waterbird species, including 5 identified only to genus, that were observed at the TSF project site in 2012 and 2013. A ✓ indicates that the species was observed.

2.2 Nesting Activity

All nests and nest starts identified within or near[1] the project during the 2012 and 2013 nesting seasons were documented (Exhibit 2). The month each nest was found during 2013 is shown in Figure 1[2]. A total of ten bird species were documented nesting in or near the 2012-2013 work areas (Table 2 and Figure 1). Additional species that were found nesting in offsite Mitigation Lands or future project lands are not included in this tally. Burrowing owl was the only special concern species nesting within or near the project site. Loggerhead shrike is known to nest in the vicinity of the TSF project, but was not found on or within setback distance of the project site. Nesting was documented spanning the months of February through August. The peak nesting period, in terms of number of nests and number of species nesting was late April through May. The horned lark was the most abundant nesting species, with 15 nests documented within or near the project in 2013.

According to the approved Topaz Construction Phase Programmatic Nesting Bird Management Plan (Althouse and Meade, Inc. April 2013, revised August 2013) a “nest start” is defined as “a new nest that is under construction but that has not yet been completed, and that does not contain eggs or young.” Nest starts were removed when the presence of a complete nest would conflict with construction activities or would present a danger to the birds. Sixteen nest starts were removed in 2013 from active construction areas. In some cases, nesting material was removed from the same location and replaced by the same birds multiple times. Nest starts of four bird species and one unidentified species were removed: mourning dove, house finch, common raven, and Western kingbird.

---

[1] Within setback distance of the project, typically 250 feet but may vary.

[2] Month nest was found does not always indicate month nesting was initiated.

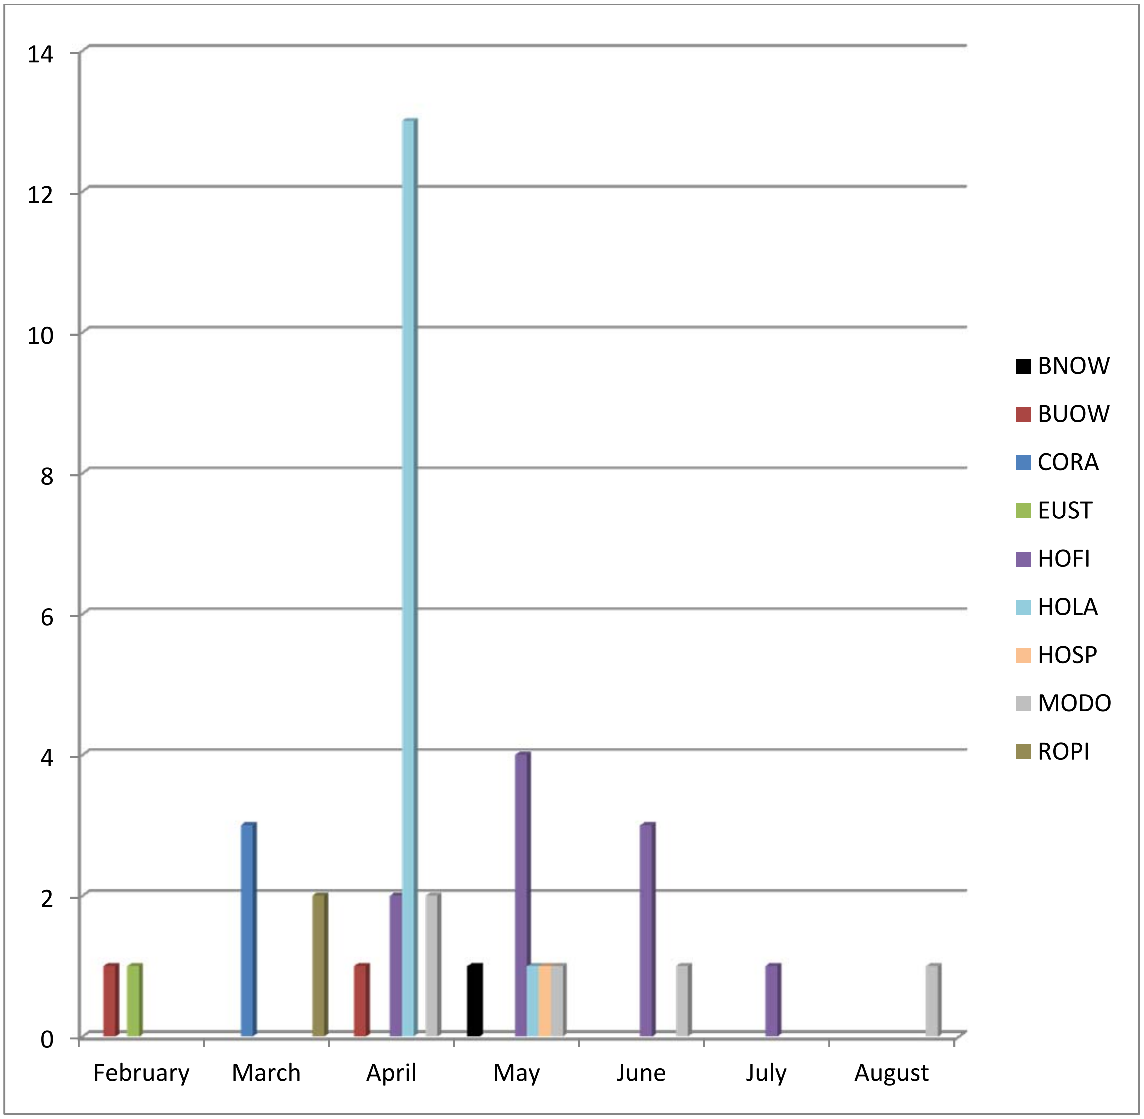

FIGURE 1. 2013 NESTING DATA BY MONTH. The number of nests located within or near the TSF project area for each species in 2013. Bird acronyms are defined on page iv, above.

2.2.1 Discussion of nesting by species 2012-2013

Horned Lark: Horned larks nest on the ground in a woven grass cup, often placed in a small depression. They prefer patchy short-grass conditions with bare spots. Array areas with newly vegetated ground provided a preferred nesting substrate. Vegetated areas adjacent to based roads were also preferable nesting sites for horned larks.

In 2013, a total of 14 active horned lark nests were located and monitored within and near the TSF project (Table 2 and Figure 1). In comparison, 47 active horned lark nests were located and monitored in 2012. Although the area covered by nest surveys each year differed in size and habitat structure, the comparison is consistent with a general reduction in nesting activity observed during 2013. Severe drought is likely responsible for fewer nests being found in 2013. Substantially lower annual rainfall occurred throughout California that year. For example rainfall totals for Atascadero, California (34 miles to the west of the TSF) for the calendar year 2012 and 2013 were 15.34 and 2.93 inches, respectively. Vegetation production observed in the Carrizo Plain was correspondingly low, and affected food availability for nesting birds.

Eleven of the 14 nests found in 2013 failed before nestlings fledged, putting nest success at 21.5 percent (3 fledged nests) and nest failure at 78.5 percent. All 11 failures were determined to be depredated by ravens, ground squirrels, and other wildlife. Nest monitoring observations indicated that ravens were the most frequent predator. Interestingly, we noticed that nestling survival appeared to be higher for nests near or adjacent to heavily utilized access roads and work areas. One of the three successful horned lark nests was located within three feet of the main site access road (Helios Way). In general, nests that were closer to active access roads remained intact for a longer period of time without predation, when compared to nests in the arrays. Proximity to active work areas or roads appeared to deter predators to some degree, thereby reducing predation rates.

Western Meadowlark: Western meadowlarks nest on the ground in taller grassland habitats. No meadowlark nests were found in current or future work areas in 2013. This was likely due to the severe drought that greatly limited grass production and the lack of suitable nesting habitat in the work areas during this timeframe.

House Finch: House finches nested or attempted to nest on construction equipment and materials throughout the project site (Photo 5). Preferred nesting areas were in the electrical coils temporarily hung on solar panels during the panel installation process (Photo 6), and openings in cardboard boxes containing tilt brackets. The number of house finch nests increased from two nests in 2012 to ten nests in 2013 (Figure 2). This increase in numbers of nests coincided with a relatively abundant nesting substrate (panel electrical wiring), which was not as common on site in 2012. Nest success in 2013 was 20 percent (2 of 10).

Photo 5. Example of house finch nests in panel supports. Photograph of P. Gaede.

Photo 6. Example of house finch nest in electrical coils. Photograph by P. Gaede.

Mourning Dove: Mourning doves are opportunistic with nest placement. Nests are a platform of twigs with little formation of the nest. Mourning doves nested or attempted to nest on the ground, under pallets, on construction equipment, and on the ledges of material and cardboard in various areas of the project site. While nests were infrequent, the overall nesting behavior lasted longer than for other nesting birds on the site, with nesting behavior noted until August 2013. Of the five mourning dove nests located in 2013 work areas, none successfully fledged any young. Predation appeared to be the primary factor in nest failure.

Common Raven: This species nested almost exclusively on power poles within and around the project site. They also attempted to nest on heavy equipment. Nesting materials were removed regularly from some nest sites to prevent nesting near work areas or locations deemed dangerous for the birds. For nest starts on equipment, removing the initial nesting material and moving the equipment to a new location proved to be the most successful method of discouraging nesting by this species. Three common raven nests were active near the project site in 2013; additional nests were detected on PG&E transmission towers and other power poles in the general vicinity of TSF.

Burrowing Owl: Burrowing owls nested in two locations immediately adjacent to the TSF project site. One nest successfully fledged in Block 10 with four young. One nest west of Block 15 was observed to have two chicks in July 2013. It is not known if both fledged successfully. A third nest (not reported in Table 2) was located between Blocks 3 and 4 on CDFW Mitigation Land. It had two chicks in June 2013. It was not known if chicks fledged; there were no observations of chicks in July and August of 2013.

Barn Owl: Barn owls occupied an abandoned building at the former Arco solar plant in what is now Block 11. Two fledglings were present in May 2013; however both of these young owls may have died. One barn owl carcass was found offsite in June, and another was found in the vicinity of the Arco building in August 2013. Cause of death was not determined for either carcass.

Rock Pigeon: Rock pigeons inhabited the abandoned building at the former Arco solar plant area in what is now Block 11. Two pigeon nests were found in the building with eggs in March 2013, both of which were presumed to have fledged.

House Sparrow: One house Sparrow nest was located in a storage container along the western perimeter road of Block 14 in May. Nesting success was unknown.

European Starling: One European starling nest was located in the handle of a storage container at the Topaz construction trailers in February 2013. Nesting success was unknown.

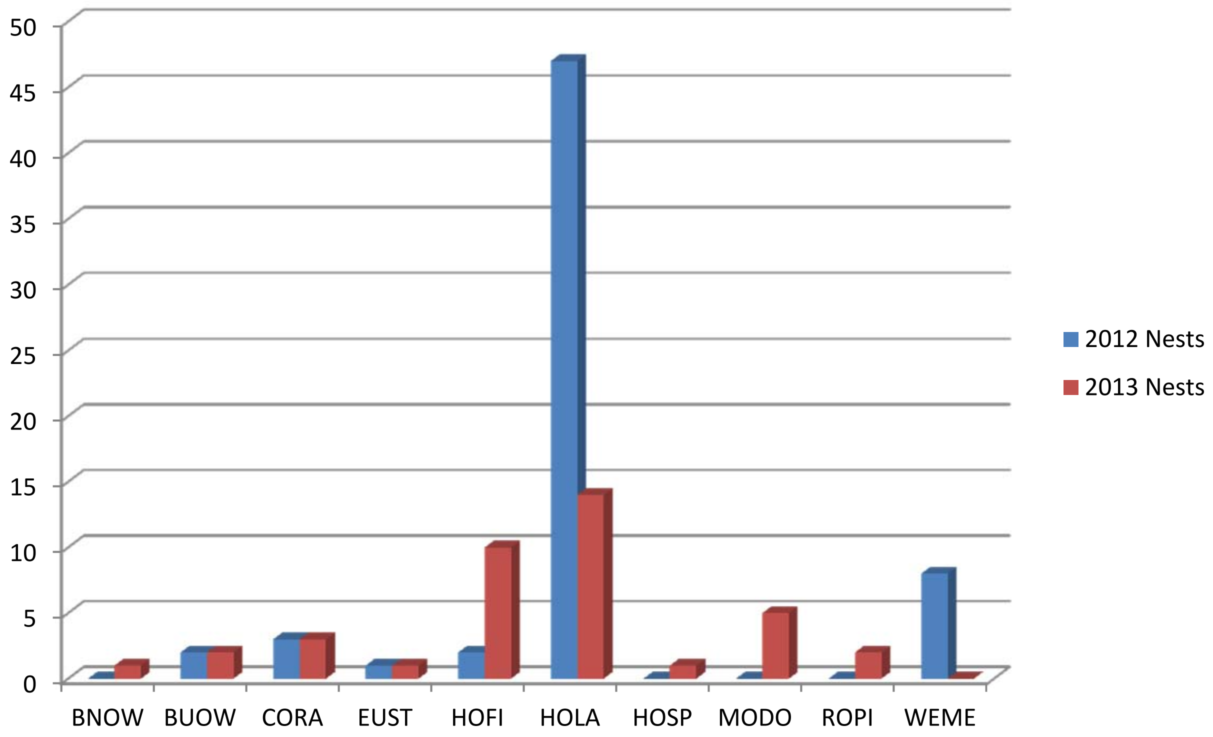

FIGURE 2. 2012-2013 NEST COMPARISON. The number of nests located within or near the TSF project area for each species is provided for 2012 and 2013. Bird acronyms are defined on page iv, above.

2.3 Nest Deterrents

Flashing tape and bird netting were used to prevent nesting on materials and equipment. Both of these methods were effective. Flashing tape was used effectively to keep house finches from nesting on equipment. Bird netting was used on tilt bracket boxes and other material stacks. When adequately secured and maintained, netting was very effective at keeping birds from nesting on materials stacks, but wildlife entrapment and entanglement was a risk. A concerted effort by workers to maintain netting in good condition minimized entrapment and entanglement. Flashing tape was often used on netting to make it more visible to birds. One avian fatality in 2013 was attributed to entanglement, a rock pigeon in the Block 11 laydown area.

Medium-voltage collector line power poles across the site were fitted with nest and perch diverters when installed. The steel power poles have a seven-inch diameter at the top where it was determined that raptors and ravens could potentially construct nests. Nest deterrents included installation of “Zena Cones” fitted to the top of the pole which eliminated the possibility of nest construction. The cones are made of high density polyethelyne and are bolted to the steel pole (Zena Design 2013).

Perch diverters of two types were used on power poles. Four inch tall spike strips were glued to the tops of the steel power pole cross-arms to prevent raptors from using the poles as hunting perches. Observations suggest the spike strips are largely ineffective at preventing raptors from perching on the cross-arms, as biologists have made numerous observations of red-tailed hawks and golden eagles perching on them. Triangle perch diverters were used on narrow cross-arms found on the wooden power poles used to provide power to the Topaz construction trailers, as well as on the narrow support brackets on the steel riser poles. Ravens had no problem perching and attempting to nest on the cross-arms and support brackets that had triangle perch diverters installed. Raptors, however, did not attempt to perch or nest on cross-arms either before or after diverter installation.

2.4 Avian and Other Wildlife Fatalities

General biological monitoring of the Topaz Solar Farms work areas documented bird, bat, and other wildlife fatalities. Avian fatalities are shown in Exhibit 5. Additionally, structured avian fatality surveys were conducted as part of the BMAP that were focused specifically on avian fatality detections. All avian and other wildlife fatalities identified on site from January through December 2013 are provided in Appendices A and B. Cause of death is provided in the tables when known, and is summarized in Table 3, below.

A total of 66 avian fatalities were documented on or near the TSF project site in 2013 (Table 3). Cause of death was not determined for 36 of the 66 fatalities (54.5 percent). For many of the incidents where the cause of death was undetermined, predation was the most likely culprit, but it was often times difficult to rule out other causes, such as those cases when only feather piles were found. Predation (presumed or confirmed) accounted for 21.2 percent (14 birds) of the fatalities. Peregrine and prairie falcons are likely the most prevalent predator of birds in the area; however, common ravens, other raptors, and canids are also potential predators that occur commonly within the project site. Electrocutions accounted for 12.1 percent (8 common ravens). All eight electrocutions were due to a single cause: faulty wildlife protector caps on the medium-voltage overhead power line riser poles. Replacement of the wildlife protector caps with a new design eliminated the electrocutions (see Section 2.4.1 for details regarding adaptive management for electrocutions on riser poles). Entanglement was listed as cause of death for one bird in 2013, a rock pigeon found beneath netting in the Block 11 laydown (1.5 percent). Collision was presumed to be the cause of death for one fatality in 2013, a lesser goldfinch that was found beneath an array table under construction, with no module in place. No collision deaths were confirmed or presumed of birds flying into solar panels. An unidentified bird carcass was removed from the wheel wash station water tank where it presumably fell through the grates; cause of death was listed as drowning. Five avian fatalities were associated with nests: a nestling European starling that apparently fell out of the nest, and a house finch nest that was incidentally damaged during movement of materials that resulted in loss of four eggs. The nest was not known to be in the materials until workers discovered it damaged.

Table 3 lists the total number of fatalities recorded and cause of death. Additionally, the table lists whether any of the fatalities were related to construction activities or operation activities. Analysis of avian fatality data collected for the BMAP is provided in Section 3.2. The survey methodology used for BMAP studies allows calculation of bird fatality rate as a measure of the number of fatalities per unit area per unit time.

TABLE 3. 2013 AVIAN MORTALITY CAUSE OF DEATH. Breakdown of causes of death for all avian fatalities recorded at the TSF project site in 2013.

Cause of Death	Species	Number of Fatalities	Related to Construction Activities	Related to Operation Activities
Unknown	AMCO, GRRO, HOLA, MODO, HOFI, BNOW, SASP, CORA, SORA, ROPI, Unidentified, Domestic chicken	36	Unknown	Unknown
Predation	CORA, MODO, HOLA, BUOW, ROPI, BNOW, EAGR, Domestic chicken	12	No	No
Presumed Predation	AMCO, MODO	2	No	No
Electrocution	CORA	8	No	Yes
Entanglement	ROPI	1	Yes	No
Collision	LEGO	1	Yes	No
Drowning	Unidentified	1	Yes	No
Nest Damage	HOFI	4 (eggs)	Yes	No
Fell out of Nest	EUST	1 (nestling)	Yes	No
Total		**66**	**8**	**8**

2.4.1 Adaptive Management

The Year 2 first quarter period of January to March 2013 was the first reporting period where medium-voltage collector lines were energized. Energized overhead lines extended from the west side of Block 1 east to Block 7 during this period. For the second quarter period of April to June 2013, Blocks 8-10 were in the process of becoming energized. Overhead collector lines extend south from Block 7 to the northwest corner of Block 9, east to the center of Block 9, then south into Block 10.

The first quarter monitoring report discussed the electrocution of six common ravens on riser poles associated with the medium-voltage collector lines. Two additional common raven electrocutions occurred in early April.

By design, there are no exposed live parts on the riser poles. The cables are insulated and energized components of the lightning arrestors that are not individually insulated have insulated wildlife protector caps on top of them preventing exposure to wildlife and workers (note arrow on Photo 7). It was determined that the common denominator between the electrocutions was a dislodged wildlife protector cap on the lightning arrestors, and suspected that raven nest-building activity dislodged the caps, exposing the ravens to live parts which, if touched, would complete a phase-to-phase or phase-to-ground circuit resulting in electrocution of the bird.

The problem was determined to be the lightning arrestor cap design, so a different style of cap was installed. This new cap was installed on each lightning arrestor on all energized riser poles by April 22, 2013. For future phases of construction, all riser poles will also be outfitted with the new lightning arrestor caps. The last documented bird electrocution was April 14, 2013. At that time a total of eight common ravens had been electrocuted on riser poles. After wildlife protector caps were replaced, No electrocutions have occurred since the wildlife protector caps were replaced.

Photo 7. Riser pole showing insulated cables and insulated wildlife protector caps (arrow) covering energized un-insulated parts of the lighting arrestors.

2.5 Bat Surveys

An acoustic monitoring survey for bats on the project site was conducted on the night of August 14, 2013 using a Pettersson D240x (Pettersson Elektronik, Sweden) bat detector and Sonobat® (v.3.1 US west; DNDesign, Arcata, CA) acoustic analysis software. The detector was placed on the south fence of the Dust Control Pond (DCP) and recorded bat calls from 20:00 to 23:07. All detected bat calls were analyzed and identified using the analysis software. Table 4 provides a list of 6 bat species detected and assigned with a discrimination probability of 0.95 or higher. A seventh bat species, the little brown bat (*Myotis lucifugus*), was possibly detected, but the call did not have a high enough discrimination probability (0.549) to be assigned with confidence.

TABLE 4. TOPAZ SOLAR FARMS BAT LIST. Six bat species detected at the Topaz Solar Farms project site in 2013 are listed. Special status designations from CDFW and Western Bat Working Group (WBWG) are provided, as well as the highest discrimination probability for each species from the recorded calls.

Common Name	Scientific Name	CDFW Status	WBWG Status	Highest Discrimination Probability
Big Brown Bat	*Eptesicus fuscus*	None	Low	1.0000
Silver-haired Bat	*Lasionycteris noctivagans*	Special Animal	Medium	0.9558
Western Small-footed Bat [=Western Small-footed Myotis]	*Myotis ciliolabrum*	Special Animal	Medium	0.9999
Yuma Bat [=Yuma Myotis]	*Myotis yumaensis*	Special Animal	Low-Medium	0.9995
Canyon Bat [=Western Pipistrelle]	*Parastrellus hesperus*	None	Low	1.0000
Mexican Free-tailed Bat [=Brazilian Free-tailed Bat]	*Tadarida brasiliensis*	None	Low	1.0000

No bat roosts are known to be present within or near the Topaz project site. Since construction started in December 2011, two bats have been found, in separate incidents, roosting beneath cloth tarps on dumpster bins. Biologists kept workers from the areas until the bats left at night, and the following morning the bats had not returned and the tarps were better secured to prevent entry.

One bat has been found dead at the project site since start of construction. A worker reported a bat carcass in a module box that was unloaded from a transport container box in August 2013. The container had not been opened since shipping from Malaysia. The bat was tentatively identified as a Malaysian fruit bat; the specimen was preserved and submitted to the Santa Barbara Museum of Natural History for further evaluation.

3.0 Bird Monitoring and Avoidance Plan

The BMAP study utilizes avian use surveys and avian fatality surveys to produce a risk index for various project components deemed to be potentially dangerous to birds, including Array Areas, Overhead Powerlines, and Energized Equipment (Substation). Offsite grassland areas were used as Reference sites to compare Bird Utilization Rates, Bird Fatality Rates, and ultimately, Bird Risk Index. The BMAP study has two primary goals:

Goal 1. Provide Project owners/managers with scientifically-based risk analyses to facilitate implementation of Adaptive Management actions to minimize conflicts between Project components and birds.

Goal 2. Provide a rigorous scientific study of avian use and mortality associated with specific components of an industrial scale photovoltaic solar facility that can be used by wildlife regulators as a planning tool for future solar projects.

To accomplish these goals, the BMAP outlines five Objectives with specific Tasks:

Objective 1. Assess changes in total bird abundance, species composition, and species richness relative to development and operation of the Project compared to undeveloped reference sites;

Task 1.1: Implement Avian Use Surveys.

Task 1.2: Submit quarterly and annual monitoring reports.

Objective 2. Calculate Bird Utilization Rate, Bird Fatality Rate, and Bird Risk Index for three specific Project components (Array Areas, Overhead Powerlines, Substation/Switching Station);

Task 2.1: Implement Avian Fatality Monitoring Surveys, Searcher Efficiency Trials, and Scavenger/Carcass Removal Trials.

Task 2.2: Run calculations on survey data according to methods in Section 5.4.

Task 2.3: Submit quarterly and annual monitoring reports.

Objective 3. Conduct risk assessment analyses for each Project component based on calculated Bird Utilization Rate, Bird Fatality Rate, and Bird Risk Index;

Task 3.1: Prepare a written analysis of survey data and calculated Bird Risk Index for each Project component to be included in the annual report.

Objective 4. Inform TSF facility managers of Adaptive Management requirements when Bird Risk Index and/or Bird Fatality Rate indicates significance thresholds for avian mortality have been reached (refer to Section 6.0);

Task 4.1: Submit quarterly and annual monitoring reports.

Objective 5. Prepare a scientific paper describing the results of avian use surveys and avian fatality monitoring surveys, and the conclusion regarding the risk level that the Project poses for avian resources.

Task 5.1: Within one year of completion of the study data collection, prepare and submit a scientific paper to the County of San Luis Obispo.

3.1 Avian Use Surveys

Avian Use Surveys commenced in November 2011, prior to the start of construction, to gather baseline data on bird use in the project area. Avian Use Survey data informs the species composition, species abundance and species richness calculations (Section 3.1.3) and Bird Utilization Rate calculations (Section 3.2.3). Bird Utilization Rate is ultimately used in Bird Risk Index calculations (Section 3.5). Construction of the TSF project commenced in December 2011 in a limited footprint, and slowly expanded in area throughout 2012 and 2013. Avian Use Surveys were conducted monthly from November 2011 through December 2013.

3.1.1 Methods

Sixty-three randomly selected survey points were selected monthly across all six phases of the TSF project site in active construction areas and future work areas, as well as offsite reference sites (Exhibit 3). Each month, as the construction area increased in size, more of the survey points occurred in developed areas. Points located within future project areas that are not developed at the time of the survey are categorized as Baseline. The Baseline category is represented by cropland habitat[3], whereas the Reference Site category is grassland. The 63 survey points conducted each month included 31 inside existing or future array areas, 18 along existing or future overhead power lines, 10 in grassland reference sites and 4 at the substation.

The five Survey Area Categories covered by Avian Use Surveys are:

- Array Area (built solar arrays);
- Energized Equipment (substation yard);
- Overhead Powerlines (linear areas under medium-voltage collector lines);
- Reference (undisturbed grasslands outside of the project footprint); and
- Baseline (cropland areas to be developed into solar arrays).

Each survey point consisted of a circular survey area with a 50 meter radius (1.94 acre), within which a ten minute bird use point count was conducted between first light and 11:00 a.m. Bird use counts differ from bird abundance counts by tallying every bird that enters the survey area, including birds that leave and re-enter the survey area. For each bird detection within the survey area, data is recorded for number of each species, behavior (e.g. fly-over, on the ground, perching, foraging, etc.), height, and interactions with facility components.

3.1.2 Results

Between November 2011 and December 2013 a total of 1,638 survey points were selected. Of these points, seven were missed during the surveys and an additional 83 points were dropped from the analyses because their Survey Area Category became obsolete due to changes in

---

[3] Blocks 14 and 15 were built on natural grassland habitat, therefore surveys conducted in Blocks 14 and 15 prior to start of construction were counted as Reference Site instead of Baseline.

construction. Data from 126 point counts conducted in November and December 2011 was also omitted so the analysis would encompass seasonal variation between two full years of surveys.

In 2012 and 2013, we completed 1,422 point counts covering approximately 2,759 acres of land to inform species composition, species abundance, species richness, Bird Utilization Rate and Bird Risk Index (Table 5). The number of survey points conducted increased from 2012 to 2013 for the three categories that consist of project components: Array Areas, Energized Equipment and Overhead Powerlines. Baseline points decreased, as there was less undeveloped area in 2013.

The Baseline category had a total of 621 observation point counts, the highest of all categories, covering approximately 1205 acres of cropland habitat. As more of the project site becomes developed, the gap between baseline and Array Areas will decrease. Array Areas had 296 point counts covering approximately 574 acres of land. Reference Sites had 233 point counts, covering approximately 452 acres of grassland habitat. Overhead Powerlines had 172 point counts, covering approximately 334 acres of developed land beneath and immediately adjacent to power lines. A total of 100 point counts were conducted at the substation for the Energized Equipment category, covering 1,194 acres of land within and surrounding the substation.

TABLE 5. AVIAN USE SURVEY POINT COUNTS. The number of point counts conducted in 2012 and 2013 is listed for each of the five Survey Area Categories. Cumulative total and acreage is also listed.

Survey Area Category	Number of Obs. Pt. Counts 2012	Number of Obs. Pt. Counts 2013	Total Number of Obs. Pt. Counts	Total Survey Area (Acres)
Array Areas	69	227	296	574.24
Energized Equipment	48	52	100	194.00
Overhead Powerline	64	108	172	333.68
Reference Site (Grassland)	120	113	233	452.02
Baseline (Cropland)	416	205	621	1204.74
Total	**717**	**705**	**1,422**	**2,758.68**

The five Survey Area Categories used as treatment types in this study comprise different habitat elements that influence species composition, abundance and richness.

The Array Area category includes point counts conducted within solar array areas during active construction and in completed form. The habitat consists of rows of passive (non-moving) photovoltaic solar panels mounted to steel racking ranging from approximately 2 to 5 feet off the ground. The ground is seeded with a native seed mix to revegetate array areas to naturalized grassland habitat; vegetation density varied from 0 to 60 percent cover. Array Area survey points may also include perimeter fences, photovoltaic combining switchgear houses, as well as array roads.

The Energized Equipment category includes point counts conducted around the perimeter of the substation. The survey area includes the substation perimeter fence, transformers, power lines, and other electrical components. Within the substation fence the ground is gravel with no vegetation. Outside the perimeter fence, the ground is bare dirt with some patches of grass.

Overhead Powerline surveys represent areas underneath medium-voltage collector lines within the project. Vegetation varies depending on location; most powerlines are along array or access roads, however some locations are outside the fenced project areas in annual grassland habitat.

Reference Sites included point counts conducted on mitigation lands owned by California Department of Fish and Wildlife. Reference Sites are composed of annual grassland habitat.

The Baseline survey category represents point count locations that were conducted in cropland habitat that will be developed into Array Areas. The habitat consists of large open areas of crop stubble.

3.1.3 Species composition, species abundance and species richness

Avian Use Surveys conducted at the TSF project were designed to collect data on *bird use* within a predetermined survey area; data were not collected on the actual number of individual birds in that area. In this section we compare 2012 and 2013 bird use data among the five Survey Area Categories) as species composition, species abundance and species richness. Data from 2011 is omitted for reasons discussed above in Section 3.1.2. Species composition looks at which bird species were detected in the Survey Area Categories. Species abundance is a measure of how abundant each of the species were within each category. Species richness is a measure of the number of different species in a given area.

Species composition consisted of 48 bird species and three unidentified bird species in 2012 and 2013 (Table 6).

Species abundance is examined in the following two ways:

- Overall Total No. Detections per Species
- Average No. Detections per Observation Point within each Survey Area Category

Overall total number of detections per species is simply a count of detections for all observation points in all five Survey Area Categories combined. This number shows how abundantly each of the species were detected by the surveys overall. It is helpful in understanding overall abundance of each species relative to abundance of other species within and near the TSF project, but does not provide comparative information among treatment types. Average number of detections per Observation Point takes this into account, and provides better understanding of how abundantly each species occurred within the different Survey Area Categories. This number is calculated using the same formula as Bird Utilization Rate (see Section 3.2.5), except that it is per species, whereas Bird Utilization Rate is overall bird use for all species. Combined with habitat description information, this number suggests preferred habitat areas for each species (see descriptions above, in Section 3.2.2).

The 10 most abundantly detected species, listed in decreasing order of abundance, were: horned lark (5,392 detections), house finch (1,416), common raven (677), savannah sparrow (473), long-billed curlew (466), brewer’s blackbird (450), Western meadowlark (311), mountain bluebird (221), mourning dove (190), and European starling (182). The most frequently encountered species, the horned lark, was detected more than three times as often as that of that of the second most frequently encountered species, the house finch. Horned larks are abundant year-around residents that commonly form large flocks in winter on the Carrizo Plain. Both the horned lark and house finch were detected in high numbers in Baseline areas consisting of cropland habitat, and were also frequently detected in project areas. Long-billed curlew and mountain plover had high detections in Baseline and Reference Site areas in 2012, almost no detections in the 2012 project areas, and were not detected at all in 2013. Both of these species are winter visitors to the Carrizo Plain and fluctuate widely in local distribution and numbers from year to year. They are almost exclusively associated with undeveloped habitats. Nineteen species were represented by a single detection consisting of a single bird.

Table 6. Species Composition and Abundance. All bird species detected during Avian Use Surveys in 2012 and 2013 are listed, with the average number of bird use detections per observation point calculated for each of the five survey area categories. Total detections for each species are provided at far right. Species are listed in decreasing order of abundance according to the total detections column.

Species	**Array Area** Ave. Detections per Obs. Pt.	**Energized Equipment** Ave. Detections per Obs. Pt	**Overhead Powerline** Ave. Detections per Obs. Pt	**Reference Site** Ave. Detections per Obs. Pt	**Baseline** Ave. Detections per Obs. Pt	**Total Detections**

Similar to species abundance, species richness is examined in the following two ways (Table 7):

- Total No. Species Detected Per Survey Area Category
- Average No. Species per Observation Point within each Survey Area Category

Table 7 and Figure 3 present species richness as the total number of species observed in all Observation Points within each Survey Area Category, by year and overall. This calculation accurately portrays the difference in annual species richness, 39 species in 2012 and 32 species in 2013, as the number of Observation Points is similar (717 and 705, respectively; see Table 5, above). However, direct comparison of species richness calculated in this manner for each of the survey area categories provides an inaccurate assessment due to the significant differences in number of Observation Points among the treatment types and from year to year. Average number of species per Observation Point within each of the treatment types is a better method for evaluating the difference in species richness among treatment types. For example, the Array Area category had an increase in the total number of species detected from 2012 to 2013, but the average number of species per Observation Point decreased from 1.28 to 1.18. The number of Observation Points increased from 69 in 2012 to 227 in 2013 (Table 5), creating this difference. The same is true for Overhead Powerline.

All five Survey Area Categories showed a decline in species richness from 2012 to 2013 based on average number of species detected per Observation Point. With severe drought conditions present in 2013, this decline is consistent with our general observations of fewer birds, and overall nesting declines for most species in the area (refer to Section 2.3).

Among the treatment types, Energized Equipment had the highest species richness with an overall average of 1.33 species detected per Observation Point. A high number of species detected in 2012 contributed to this result. Interestingly, the substation was under construction and was not energized in 2012 as it was in 2013. Array Area and Overhead Powerline categories were similar, with 1.20 and 1.19 species detected per Observation Point. As these two treatment types are in close proximity to each other and contain similar and at times overlapping habitat features, this result was expected. Reference Site and Baseline categories represent the two undeveloped habitat areas. Reference Sites recorded an average of 1.12 species per Observation Point, while Baseline had 0.89 species per point. This result is interesting in light of the fact that Baseline had almost three times as many Observation Points completed as Reference Site (621 and 233, respectively). Therefore, it can be said that species richness in offsite annual grasslands is higher than in fallow croplands. Species richness is also higher in all three project component categories than in the two offsite undeveloped categories.

TABLE 7. SPECIES RICHNESS 2012-2013. Species richness is listed separately for 2012, 2013 and overall for the two years as total number of species detected within each category. Additionally, species richness is listed as average number of species detected per observation point.

Survey Area Category	2012 Total Species	2013 Total Species	Overall Total Species 2012-13	Average No. Species per Obs. Pt. 2012	Average No. Species per Obs. Pt. 2013	Overall Average No. Species per Obs. Pt.
Array Area	18	20	26	1.28	1.18	1.20
Energized Equipment (Substation)	14	10	15	1.60	1.08	1.33
Overhead Powerline	12	15	18	1.39	1.06	1.19
Reference Site (Grassland)	18	13	22	1.22	0.90	1.12
Baseline (Cropland)	29	15	33	1.03	0.75	0.89
Totals	**39**	**32**	**51**	-	-	-

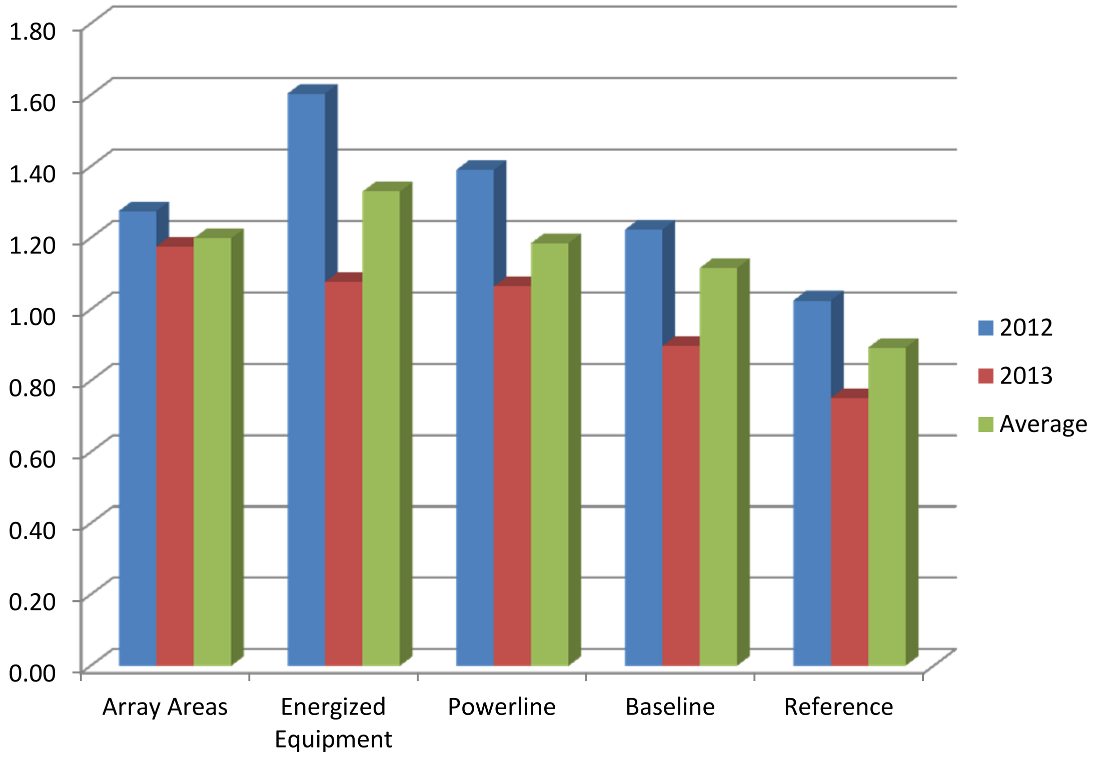

FIGURE 3. SPECIES RICHNESS 2012-2013. Species Richness is indicated as the average number of species detected per observation point for each survey area category, by year and overall.

3.1.4 Bird Utilization Rate

Bird Utilization Rate (BUR) is calculated as the average number of birds observed per Observation Point count[4]. With each Observation Point count consisting of a 10 minute tally of bird use within a circular survey area totaling 1.94 acres, the result is a rate that indicates bird use per unit time (10 minutes) per unit area (1.94 acres). This rate can be extrapolated in a variety of ways for project to project comparisons (refer to discussion in Section 4.0).

We calculated Bird Utilization Rate for five Survey Area Categories for 2012 and 2013 separately and cumulatively (Table 8): Array Areas, Overhead Powerlines, Energized Equipment (Substation), Reference Site (grassland) and Baseline (cropland).

Array Area and Baseline have the highest cumulative BUR at 7.72 and 7.66 birds per Observation Point. With 6.97 birds per Observation Point, Reference Site category had the third highest BUR, and Overhead Powerline and Energized Equipment had the lowest BUR at 5.55 and 5.47 birds per Observation Point.

Compared to 2012, BUR declined for all five Survey Area Categories in 2013. Array Areas declined the least (-39.6 percent) while Overhead Powerline declined the most (-62.6 percent).

TABLE 8 BIRD UTILIZATION RATE. BUR is calculated as the average number of birds observed per Observation Point for 2012 and 2013, as well as cumulatively for both years for each of the five Survey Area Categories. Percent change from 2012 to 2013 is also listed.

Survey Area Category	2012 BUR	2013 BUR	Percent Change	Cumulative BUR 2012-13
Array Area	11.1	6.7	-39.6%	7.72
Energized Equipment (Substation)	7.1	3.9	-45.1%	5.47
Overhead Powerline	9.1	3.4	-62.6%	5.55
Reference Site (Grassland)	9.1	4.7	-48.4%	6.97
Baseline (Cropland)	9.3	4.2	-54.8%	7.66

---

[4] ABPP document and 2012 annual report calculate BUR as average number of unique bird observations per observation point. This method counts a multi-bird observation such as a flock as a single unique observation. For this annual report and future reports we modified the calculation of BUR as average number of birds observed per observation point. This method yields a more meaningful result in terms of bird use per unit time per unit area. This method will be incorporated into the next ABPP/BMAP revision.

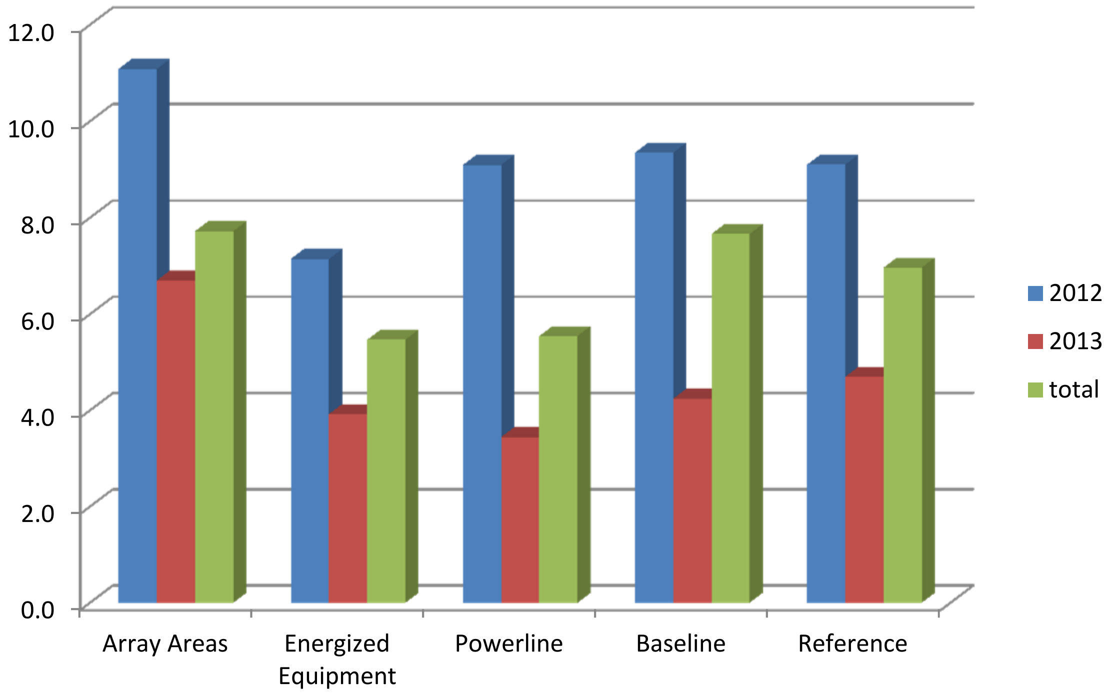

FIGURE 4. BIRD UTILIZATION RATE. Calculated as the average number of birds observed per Observation Point, BUR is compared for 2012, 2013 and an overall cumulative total.

3.2 Avian Fatality Surveys

Avian Fatality Surveys commenced upon completion of the first project components. Avian Fatality Surveys are conducted monthly at randomly selected locations within four different Survey Area Categories: Array Area, Overhead Powerline, Energized Equipment (Substation) and Reference Site. Select Array Areas were completed with construction and safe to conduct avian fatality surveys starting in October 2012. The first Overhead Powerline search plots were completed by the December 2012 survey. Energized Equipment areas were not completed with construction in 2012 and were therefore not surveyed; surveys started in February 2013.

3.2.1 Methods

Search Plots within each of the four Survey Area Categories were defined in ArcGIS as an area 480 feet long by 14 feet wide[5], which is the standard length of an array aisle, minus the bisecting road. Search plots are randomly selected each month using an ArcGIS random point generator having defined areas as the constraining polygon. Avian Fatality Surveys are conducted within

---

[5] Search plots were previously listed as 500 feet long, based on plan sheets prior to start of construction. It was decided to remove the 20 foot wide center road from transects to better account for distance surveyed within the arrays, thus transects are now considered 480 feet long.

the same search plots each day for seven consecutive days every month. Repetitive surveys increase the chance of finding fatalities in a given area before predators remove the carcass. As the TSF project progressed in construction, increasing numbers of Search Plots were surveyed monthly. By the end of 2013, a total of 114 search plots were selected in Array Area, 6 in Overhead Powerline, 4 in Energized Equipment and 114 in Reference Site. Exhibit 4 depicts the search plots covered by Avian Fatality Surveys in 2012 and 2013.

Avian Fatality Surveys are conducted on foot by trained biologists. Surveyors scan the ground and project components for bird carcasses, feathers, and marks indicating collision. When a fatality is found, data is collected on species, age and sex, location, carcass condition, cause of death, proximity to project components, and general notes.

3.2.2 Results

To date 12,656 search plots covering 1,952.4 acres (1150.5 linear miles) have been surveyed in Array Areas, resulting in detection of 14 avian fatalities (Table 9). For offsite Reference Sites, 12,365 search plots were surveyed covering 1,888.1 acres (1112.6 linear miles), resulting in detection of 26 avian fatalities. Along Overhead Powerlines, one fatality was detected in 49 search plots totaling 79.7 acres (47.0 linear miles). Energized Equipment surveys covered 304 search plots totaling 48.8 acres (28.8 linear miles), without detecting a single avian fatality (Table 9).

Cause of death was recorded for all fatalities, when known. The 41 fatalities documented during formal Avian Fatality Surveys were the result of three causes: predation, entrapment and unknown. No confirmed collisions or electrocutions were recorded in any of the Survey Area Categories. Predation was determined to be the likely cause of death in 6 Array Area fatalities and 14 Reference Site fatalities. Most of these incidents were due to raptors killing and plucking passerines such as horned lark, meadowlark and mourning dove. Four of the Predation incidents, all in Array Areas, involved domestic chickens that were likely brought onto the site by canid predators from an adjacent private residence. Predation as a cause of death is likely much higher than reported, as often times a feather pile could not be confidently linked to a predation event as opposed to a scavenging event. In these cases, cause of death was listed as Unknown[6]. Entanglement was listed as cause of death for one incident in the Reference Site category. This was a common raven chick that got tangled in nesting material. Cause of death could not be determined for 20 (48.8 percent) fatalities, 8 in the Array Areas, 1 in Overhead Powerline and 11 in Reference Site. Eleven of these occurred in Reference Site areas where predation was the likely cause of death. Nine of them occurred in project areas, all of which were described as feather piles. Our observations suggest a feather pile is the result of raptor predation, where a live bird is killed and plucked at or near the kill site. If a bird collides with something or

---

[6] Recent guidance from the U.S. Fish and Wildlife Service suggests attributing cause of death to a specific factor and including a confidence percent to indicate how confident the determination was. Data for 2014 is being collected in this manner and cause of death for all prior incidents may also be annotated as such.

otherwise dies and ends up whole on the ground, scavenging by birds or mammals results in the carcass simply disappearing rather than becoming a feather pile.

TABLE 9. CAUSE OF DEATH FOR AVIAN FATALITY SURVEY RESULTS. Cause of death is tallied for avian fatalities detected within each of the four survey area categories, 2012-2013, during formal avian fatality surveys.

Survey Area Category	Collision	Electrocution	Predation	Entanglement	Unknown	Total
Array Area	0	0	6	0	8	**14**
Energized Equipment (Substation)	0	0	0	0	0	**0**
Overhead Powerline	0	0	0	0	1	**1**
Reference Site (Grassland)	0	0	14	1	11	**26**
Totals	**0**	**0**	**20**	**1**	**20**	**41**

3.2.3 Bird Fatality Rate

Bird Fatality Rate (BFR) is calculated as the number of unique bird carcasses detected divided by the number of plots searched (Table 10). For this analysis, data is cumulative for 2012 and 2013.

Overhead Powerline and Reference Site had the highest BFR (0.0020 and 0.0021, respectively). This equates to one fatality in 79.7 acres (47.0 linear miles) of Overheard Powerlines, and one fatality in 72.6 acres (42.7 linear miles) of grassland. It should be noted that cause of death for the one fatality near the Powerlines was not determined, and cause of death for 42 percent of the Reference Site fatalities was not determined. BFR for Array Areas is 0.0011, or 14 fatalities in 12,656 search plots. This is equivalent to one fatality per 139.5 acres (82.2 linear miles). No fatalities were recorded in the Energized Equipment search plots, so the BFR is zero.

TABLE 10. BIRD FATALITY RATE. BFR is indicated for each of the four survey area categories, cumulatively for 2012 and 2013.

Survey Area Category	# Search Plots	Linear Miles	Acres	Acres per Fatality	Total # Fatalities	Bird Fatality Rate
Array Area	12,656	1150.5	1952.4	139.5	14	0.0011
Energized Equipment (Substation)	304	28.8	48.8	-	0	0.0000
Overhead Powerline	496	47.0	79.7	79.7	1	0.0020
Reference Site (Grassland)	12,365	1112.6	1888.1	72.6	26	0.0021

BFR at Reference Site areas (0.0021) was nearly double that of Array Area (0.0011), with a similar number of search plots completed (12,365 and 12,656 respectively). To test for difference in bird mortality between Array Area (completed project area) and Reference Site (natural grassland) we used a one-way ANOVA. BFR for Array Area and Reference Site were compared, and found to be significantly different. Natural grassland areas had a significantly higher number of bird fatalities per transect than did array areas (F = 3.892, p=0.0485).

TABLE 11. ANOVA BFR RESULTS. One-way ANOVA results for test between fatality number per search plot (BFR) in Array Area and Reference Site areas. The two types were significantly different with respect to the number of dead birds discovered per search plot.

3.3 Scavenger/Carcass Removal Trial and Searcher Efficiency Trial

The BMAP study requires two types of trials to determine bias in the data. The scavenger/carcass removal trial investigates how fast a carcass gets scavenged within each of the four Survey Area Categories. The searcher efficiency trial provides a percent of known carcasses that are found by surveyors. Data from these trials is provided as background information to evaluate potential significance of these types of bias, but is not included in the final calculations used to determine Bird Risk Index. Carcasses used in the trials were unfrozen Japanese quail purchased from a reptile feed supplier. The quail are brownish overall and are about the size of a Western meadowlark, which is roughly the average size of common bird species present at TSF.

3.3.1 Scavenger/carcass removal trial

Scavenger/carcass removal trials were conducted in May and July 2013. Carcasses were randomly placed by the trial administrator in project areas and in offsite grasslands. The carcasses were numbered and labeled with a small band of green tape around one leg.

Carcass monitoring procedures outlined in the ABPP/BMAP require carcasses to be checked the first three consecutive days after placement, twice a week for the next two weeks, and then once a week for the remainder of the 60 day trial. Monitoring stopped when 100 percent of the carcasses were scavenged (Table 12). Upon routine monitoring of the carcasses, notes are recorded of the status and condition of the carcass. In these trials, with the exception of a few feathers, the carcass was simply present or not present.

As suspected, carcasses did not last long after they were placed in the field by the trial administrator. For onsite areas, 93.3 and 94.4 percent of the carcasses were scavenged within the first three days. For offsite areas, 86.7 and 100 percent of the carcasses were scavenged within the same time period. The maximum length of time a carcass remained in place was 18 days, which was twice the length of time any other carcass remained before being scavenged.

TABLE 12. PERCENT SCAVENGED BY DAY (CUMULATIVE). Cumulative percent of carcasses scavenged by day, separated by trial number. Included is the maximum number of days a carcass remained in the field before being scavenged.

Trial	**Location**	**Number of Carcasses**	**Day 1**	**Day 2**	**Day 3**	**Wk 2 (Day 1)**	**Wk 2 (Day 2)**	**Wk 3 (Day 1)**	**Wk 3 (Day 2)**	**Max. Days Present**
			Percent Scavenged							
1	Onsite	18	88.9	94.4	94.4	94.4	94.4	94.4	100	18
	Offsite	15	60.0	100	--	--	--	--	--	2
2	Onsite	15	33.3	80	93.3	100	--	--	--	8
	Offsite	15	33.3	53.3	86.7	93.3	100	--	--	9
Onsite Average			**63.6**							**13**
Offsite Average			**46.7**							**5.5**

3.3.2 Searcher efficiency trial

Searcher efficiency trials were conducted in May and December of 2013. Prior to the commencement of the day's Avian Fatality Surveys, dead Japanese quail were randomly placed by the trial administrator in the search plots of the scheduled Avian Fatality Surveys, both on and offsite. The trial was conducted blind, meaning carcasses were placed without the knowledge of the surveyors.

After the survey crew completed the day's surveys, the trial administrator performed a follow-up on all the carcasses placed prior to the trial. This was to determine how many of the original carcasses were in place, therefore available for detection, and how many carcasses had been scavenged by wildlife. The carcasses determined to be scavenged by the time of the follow-up were removed from the detection rate equation, since it could not be confirmed if the carcass was actually present when the surveyors were in that area.

Table 13 provides detection rates for onsite and offsite carcass placements in the two trials, and an average of the two trials. The detection rate is calculated by dividing the number of carcasses found by the number of carcasses placed minus any that were predated. Onsite detection rates averaged 70.8 percent, while offsite detection rates averaged 60 percent. Detection rate was assumed to be higher in the onsite survey plots than in the grassland plots because of minimal vegetation within the onsite survey plots that provided greater visibility of the ground surface.

Onsite in the arrays, surveyors are exposed to repetitive aisles between solar panels which cast harsh shadows to the ground. Often, half of the aisle is bright with sunlight and the other half under the panels and next to the support posts is contrastingly dark with shadow. This visibility issue may affect searcher efficiency rate.

Offsite, in the grassland plot transects, surveyors are exposed to ever-changing vegetation and debris within the search plots. Offsite plots were once grazed by cattle. The remaining dry cattle dung patties spread across the landscape look very similar to the dead Japanese quail used for the searcher efficiency trial. The landscape is also covered in small divots that carcasses may lay in and be hard to detect. The vegetation is drab, as are the quail and most of the avian species present in the area.

TABLE 13. SEARCHER EFFICIENCY TRIAL. Detection rates are provided for onsite and offsite searcher efficiency trials.

Trial #	**Location**	**Carcasses Placed**	**Carcasses Scavenged**	**Carcasses Available for Detection**	**Carcasses Found**	**Carcasses Not Detected**	**Detection Rate** (percent of available)
1	Onsite	18	6	12	9	3	75.0%
	Offsite	15	4	11	6	5	54.5%
2	Onsite	15	3	12	8	4	66.6%
	Offsite	13	4	9	6	3	66.6%
Average	**Onsite**	33	9	24	17	7	**70.8%**
Average	**Offsite**	28	8	20	12	8	**60.0%**

3.4 Bird Risk Index

Bird Risk Index (BRI) is calculated in order to quantify multiple measures into a single number to facilitate comparison of the different Survey Area Categories and to monitor for trends over time. For this study, BRI is calculated as Bird Fatality Rate (BFR) divided by Bird Utilization Rate (BUR). The risk index number therefore reflects differences in bird mortality and bird use among the treatment types. Table 14 lists BUR, BFR, and BRI, calculated from avian use survey data and avian fatality survey data collected in 2012 and 2013.

The Overhead Powerline survey category had the highest BRI, at 0.00036. Although only one bird fatality was detected at powerline search plots, the total number of powerline search plots was low compared to other survey area categories, resulting in a high fatality rate and BRI. Reference Site had the second highest BRI, at 0.00030. Twenty-six fatalities were recorded in 2012 and 2013 in over 12,000 search plots, resulting in a BFR similar to that for Overhead Powerline, and a BRI only slightly lower. Array Areas had a BRI of 0.00041, approximately a quarter of that calculated for Overhead Powerline, and a third of the BRI calculated for Reference Site. No mortality was documented at the Energized Equipment category, therefore the BRI is zero.

TABLE 14. BIRD RISK INDEX. BUR, BFR, and BRI are provided for the Array Area, Overhead Powerline, Energized Equipment and Reference Site search plots.

Survey Area Category	Bird Utilization Rate (BUR)	Bird Fatality Rate (BFR)	Bird Risk Index (BRI)
Array Area	7.72	0.0011	0.00014
Energized Equipment (Substation)	5.47	0.0000	0
Overhead Powerline	5.55	0.0020	0.00036
Reference Site (Grassland)	6.97	0.0021	0.00030

3.5 Adjusted Avian Fatality Rates

Searcher efficiency and scavenger removal trials were conducted to account for systematic reduction of fatality detections resulting from sampling procedure (bias). The trials were each repeated twice. Results between the original and repeat trial efforts were very different; therefore to obtain accurate measure of searcher efficiency these trials need more repetitions. For this reason, we consider trial bias data utilized here as preliminary, yet useful for fatality estimates.

Preliminary scavenger removal data collected in 2013 indicates that 64 percent of onsite carcasses and 47 percent of offsite carcasses are scavenged in the first 24 hours of the carcass being present. This means that at only 36 percent of the onsite and 53 percent of the offsite carcasses are available for detection after one day. With searcher efficiency at 71 percent of the available onsite carcasses and 66 percent of the available offsite carcasses, we adjusted avian fatality data to indicate a maximum of likely total fatalities (Table 15).

Using fatality data collected in 2012 and 2013 during formal avian fatality surveys, we calculated number of fatalities per acre per day for each of the four Survey Area Categories and extrapolated that to estimated number of fatalities per site per year, where site equals the total area of those components when the project is completed. Our fatality survey method consists of seven consecutive days of surveying the same transects. Since the first day could potentially contain carcasses present for several days, if not months, we excluded those fatalities detected on the first day and based the number of fatalities per acre per day calculation on carcasses found each of the remaining six days. This number is provided as a minimum number of fatalities detected. Using trial bias data, this number is adjusted to provide a maximum potential number of fatalities per unit area per unit time (Table 15).

For Array Area, we detected 7 fatalities (after excluding data from the first day of surveys, see explanation in paragraph above), representing the minimum number of fatalities per 1,674 acres of survey area per 95 days. Projected maximum number of fatalities for the same area and time, adjusted for trial data, is 27.4. For the completed TSF project, with 2,659 acres of array transects, we can expect a range of 42.7 to 167.2 avian fatalities per year.

For Overhead Powerline areas, we detected only one fatality in 68 acres over 80 days. Potential maximum fatalities for the same area and time, adjusted for trial data, is 3.9. For the completed TSF project, with 21.9 acres of power line transects, extrapolating and adjusting fatality number by searcher efficiency and scavenger removal trial data, we calculate a range of 1.5 to 5.7 fatalities per year.

For Energized Equipment, no fatalities were detected in 287 acres over 64 days. With a base fatality rate of zero, projected maximum fatalities would also be zero.

For Reference Site, we detected 19 fatalities in 1,622 acres over 84 days. Potential maximum fatalities based on trial data is 54.3 fatalities. To compare Reference Site range of potential fatalities with Array Area, Overhead Powerline and Energized Equipment, we calculated the number of fatalities per year per area of each category using Reference Site fatality rate. Thus, for an equivalent area of grassland as Array Area (2,659 acres), we would expect a range of 135.4 to 387.0 avian fatalities. For an equivalent area of Overhead Powerline (21.9 acres), we would expect a range of 1.1 to 3.2 avian fatalities. For an equivalent area of grassland as Energized Equipment (287 acres), we would expect a range of 0.2 to 0.7 avian fatalities.

The most interesting fatality rate comparison is between Array Area and Reference Site, where actual fatalities are 3.17 times higher and projected maximum fatalities are 2.3 times higher in offsite grassland habitat than in project array fields (see Table 15 and Figure 6):

- Array Area: 42.7 to 167.2 avian fatalities per year
- Reference Site: 135.4 to 387.0 avian fatalities per year

TABLE 15. ADJUSTED FATALITY RATES. Fatality data is indicated for minimum and maximum bird mortality rates for each of the Survey Area Categories per year, accounting for searcher efficiency and scavenger bias rate data. Calculations are shown for number of fatalities per acre per year, fatalities per site per year, and fatalities per site per year based on Reference Site fatality rate.

Survey Area Category	**Days Surveyed**	**Survey Area (acres)**	**Cause of Death**	**No. Fatalities**		**Fatalities/Ac/Yr**		**Fatalities/Site/Yr**		**Fatalities/Site/Yr (Reference Site Rate)**	
				Min	**Max**	**Min**	**Max**	**Min**	**Max**	**Min**	**Max**

			Total	**19**	**54.3**	**0.051**	**0.146**	**-**	**-**	**-**	**-**

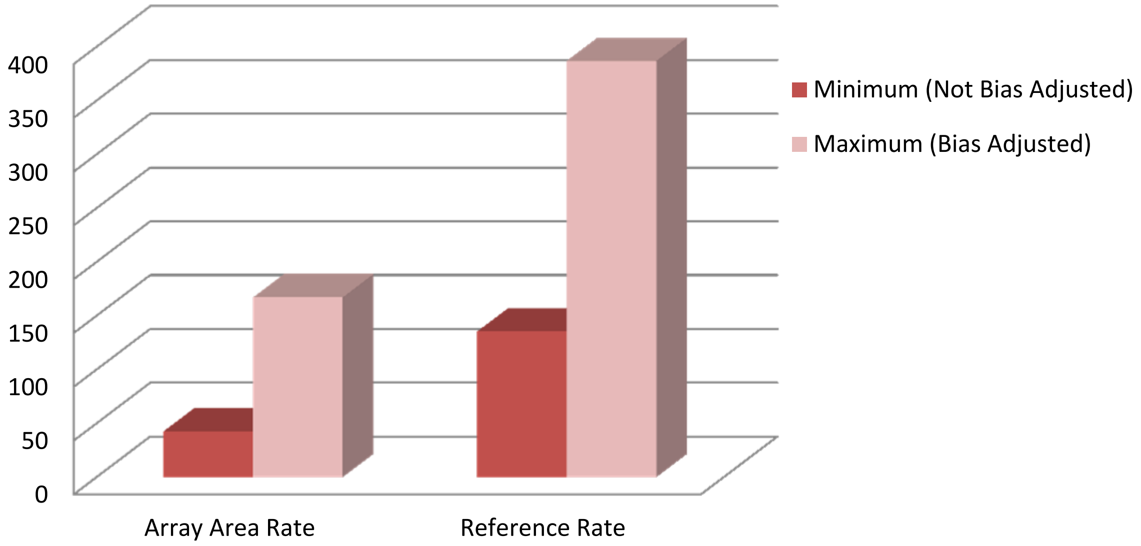

FIGURE 6. ADJUSTED FATALITY RATES. Minimum and maximum fatality rates are indicated for Array Area and Reference Site, where minimum rates are actual fatality detections, and maximum is projected adjusted by scavenger and searcher efficiency bias data. Reference Site rates are calculated based on Array Area acreage of 1,674 acres.

4.0 Discussion

4.1 General 2013 Avian Fatality Overview

Data collected during general monitoring surveys and focused Avian Fatality Surveys indicates that bird mortality at the TSF project site is lower than natural grassland reference sites, with cause of death (where cause was determined) due primarily to predation. There have been no confirmed bird collisions with solar arrays or overhead powerlines at the TSF project site. Electrocutions were confirmed for 8 common ravens in 2013, accounting for 12.1 percent of all 2013 fatalities. The electrocutions were due to dislodged wildlife protector caps on overhead powerline riser pole lightning arrestors. After all wildlife protector caps were replaced, electrocutions ceased. Overall, in 2013, a majority of the bird fatalities detected on the project site were associated with construction areas and not operation areas, suggesting that birds within construction areas are at a higher risk than those in operation areas of a passive photovoltaic solar plant.

4.2 Bird Risk Index and Cross-Project Data Comparisons

The Bird Monitoring and Avoidance Plan requires collection of data on bird use and bird mortality to inform a Bird Risk Index calculation that can be used to determine avian mortality significance thresholds. This study was designed in 2010 in consultation with the U.S. Fish and Wildlife Service (USFWS), and was modeled after studies conducted for wind energy projects. Determining significance thresholds is a requirement of the study, and is to be done in consultation with USFWS and California Department of Fish and Wildlife (CDFW) in early 2014. Since 2010, we have learned that this type of risk index study may not be part of bird mortality studies being conducted on other solar projects in California. Without similarly calculated bird risk index data from other solar projects, the calculations from Topaz Solar Farms do not have a strong frame of reference to help scientists and regulators understand the significance of bird mortality rates from Topaz versus other solar projects.

However, data collected for our BMAP study can be compared with other locations. Analysis of data for bird use and bird mortality in terms of birds or fatalities per unit time per unit area can be comparable between project sites, despite different survey methodologies. From our Avian Use Surveys we can calculate bird use per acre per day for different survey area categories (eg: Array Areas, Overhead Powerlines, etc.). Likewise, our avian fatality survey data can be used to calculate number of bird fatalities per acre per day. This type of calculation should be available from datasets collected by the various methods of fatality surveys and bird point counts conducted on other solar projects, and can be used to provide annual fatality estimates or risk assessments based on total size of array fields.

4.3 Causes of Avian Mortality

Cause of death was not determined for 54.5 percent of all avian fatalities recorded in 2013. Predation accounted for 31 percent. Most of the “unknown” fatality incidents were likely the result of predation of live birds. In these cases, all that remains is a feather pile. During scavenger removal trials, test carcasses were either there or not there, and never were reduced to a feather pile. This suggests that if a bird collides with a module and dies, it would be present as a whole carcass and would be entirely gone when scavenged. Based on guidance from USFWS, we will be modifying cause of death determination method for 2014. Instead of classifying a carcass or feather pile as "Unknown" when there is insufficient information to know with certainty, we will be classifying carcasses with the best cause of death determination based on information collected at the time of discovery, and qualifying the determination with a percent confidence.

Mortality in offsite grassland areas sampled as Reference Site was nearly double that detected in Array Areas. Because a large portion of the fatalities are the result of predation, it appears that array areas provide more structure and protection from predators. Anecdotal evidence indicates the highest rate of predation is from raptors, primarily falcons such as prairie, peregrine and merlin. These birds are powerful aerial predators that would have higher success of captures in the open grasslands than in the arrays.

Collision with solar panels as a cause of bird fatalities has not been documented at the TSF project site. We understand that collisions with panels have occurred on other industrial scale solar plants in California. If bird collisions with panels are occurring at the TSF project, it has not been detectable with current survey methods.

Trials have shown that approximately 64 percent of whole carcasses are scavenged within 24 hours within the arrays, and searcher efficiency at finding the remaining 36 percent of carcasses is 71 percent, indicating that a large proportion of bird fatalities go undetected (see searcher efficiency and scavenger removal trial data in Section 3.3, and adjusted avian fatality data in Section 3.5).

4.4 Future Work

Searcher efficiency trials and scavenger trials will be repeated to test consistency of results. We plan on repeating these two studies several times in 2014 and comparing results to previous trials.

BUR and BRI suggests array areas are less risky to birds than offsite reference grasslands. This raises several questions worth further investigation including: is duration of use by individual birds lower in array areas, is predation risk higher in grasslands without cover, are sick or morbid individuals not frequenting array areas as often, is habitat type of energized equipment areas not conducive to use by birds? Also, as the habitat in the array areas develops and matures over time, will use by birds increase within the solar plant? Some of these questions fall outside of the scope of this current study, and present an opportunity for future examination and investigation.

Appendix A – Avian Fatalities 2013

Avian fatalities detected at the Topaz Solar Farms, January through December 2013.

Species	Cause of Death	Notes
January 2013		
Horned Lark *Eremophila alpestris*	Unknown	Found about 15 feathers in Block 3 Array 4
Horned Lark *Eremophila alpestris*	Unknown	Feather pile of approximately 50 feathers in Block 1
Mourning Dove *Zenaida macroura*	Unknown	Feathers found in Cochrane area
Bird Species unidentified	Unknown	Two wings found in Block 7
Bird Species unidentified	Unknown	Primary, secondary, down, and tail feathers found in Block 1
House Finch *Haemorhous mexicanus*	Unknown	Found in Conti Laydown
Horned Lark *Eremophila alpestris*	Unknown	Feathers only in north perimeter fence of Block 8 east
Barn Owl *Tyto alba*	Unknown	Found dead on top of fence post in Block 7
February 2013		
Horned Lark *Eremophila alpestris*	Unknown	Feather pile found in Block 1
Horned Lark *Eremophila alpestris*	Unknown	Found on ground next to post in Block 9 Array 32; intact with very minor blood spots on bill and breast
Bird Species unidentified	Unknown	Feathers found in Block 1; sheared with broken tips, from mammal
Bird Species unidentified	Unknown	Feathers found in Block 4
House Finch *Haemorhous mexicanus*	Unknown	Female found on ground next to large stack of pallets in Block 7 recycling yard
Mourning Dove *Zenaida macroura*	Presumed Predation	Feather pile near a pole on the Hotline route
March 2013		
Common Raven *Corvus corax*	Electrocution	Found dead below power pole at PCVS1; feathers of one wing charred. Wildlife protector cap replaced April 22, 2013
Horned Lark *Eremophila alpestris*	Unknown	Found in trench in Block 9 Array 27; mostly feathers and bone
Mourning Dove *Zenaida macroura*	Unknown	Feather pile in Block 11 laydown; some on top of stack of tables and some on ground
Rock Pigeon *Columba livia*	Presumed entanglement	Found at bottom corner of net in Block 11 laydown
Lesser Goldfinch *Spinus psaltria*	Presumed collision	Found in Block 10 Array 3; Presumed collision with rails or arms
Bird Species unidentified	Unknown	Feather pile found in Block 10 east

Species	Cause of Death	Notes
Common Raven *Corvus corax*	Electrocution	Found at bottom of Hotline pole at PCVS4; wildlife protector cap replaced April 22, 2013
House Finch *Haemorhous mexicanus*	Unknown	Found at the Topaz Office lot; cause of death unknown
Common Raven *Corvus corax*	Electrocution	Found below power pole at PVCS1; wildlife protector cap replaced April 22, 2013
Horned Lark *Eremophila alpestris*	Unknown	Pile of feathers in Block 6
Savannah Sparrow *Passerculus sandwichensis*	Unknown	Found dead lying on a roll of wire that was hanging on the end of a rail in Block 9 Array 6
Common Raven *Corvus corax*	Electrocution	Found hanging from pole at PCVS7; wildlife protector cap replaced April 22, 2013
Common Raven *Corvus corax*	Electrocution	Found at Block 2 PVCS2; wildlife protector cap replaced April 22, 2013
Common Raven *Corvus corax*	Electrocution	Found dead on ground at PVCS3; wildlife protector cap replaced April 22, 2013
April 2013		
Chicken *Gallus gallus domesticus*	Unknown	Feather pile in Block 2 with coyote scat next to pile
Chicken *Gallus gallus domesticus*	Predation	Feather pile; feather tips sheared off
Common Raven *Corvus corax*	Electrocution	Riser pole at PVCS7; wildlife protector cap replaced April 22, 2013
Common Raven *Corvus corax*	Electrocution	Riser pole at PVCS1; wildlife protector cap replaced April 22, 2013
Bird Species unidentified	Drowning	Fell into vehicle wheel wash water tank
House Finch *Haemorhous mexicanus*	Nest damage	Failed nest; four broken eggs found on rails/tables in Block 14 Array 8
Mourning Dove *Zenaida macroura*	Unknown	Decomposed, carcass intact, downy feathers in Block 8 east
May 2013		
European Starling *Sturnus vulgaris*	Fell out of nest	Nestling found near water storage container at Move-on
Mourning Dove *Zenaida macroura*	Predation	Mourning dove kill site in Block 11 Hotline Route
Horned Lark *Eremophila alpestris*	Unknown	Feather pile west of Hotline Route, south of Tower Road
House Finch *Haemorhous mexicanus*	Unknown	Found in Block 14 west; appeared to have been dead at least one week; neck possibly broken
June 2013		
Horned Lark *Eremophila alpestris*	Predation	Male east of Arco Building in Block 11
Horned Lark *Eremophila alpestris*	Predation	Headless fledgling in Block 9 Array 2
July 2013		

Species	Cause of Death	Notes
Common Raven *Corvus corax*	Unknown	Feather pile found in Block 13 Array 12; no carcass
August 2013		
Rock Pigeon *Columba livia*	Unknown	Feather pile found in Block 4
Mourning Dove *Zenaida macroura*	Predation	Wing collected in Block 12
Common Raven *Corvus corax*	Unknown	Numerous common raven feathers Block 13
Barn Owl *Tyto alba*	Predation	Juvenile; rest of carcass found near Arco building Hotline Route between Blocks 9 and 11
Burrowing Owl *Athene cunicularia*	Presumed predation	Approximately 30 flight feathers; San Joaquin kit fox scat on feather pile Cochrane Pond buffer
September 2013		
Greater Roadrunner *Geococcyx californianus*	Unknown	Feather pile in Block 3
Horned Lark *Eremophila alpestris*	Unknown	Feather pile found in Block 6A
October 2013		
Chicken *Gallus gallus domesticus*	Presumed predation	Found in completed Block 2
Sora *Porzana carolina*	Unknown	Found on Helios Way; no visual injuries
American Coot *Fulica americana*	Presumed predation	Feather pile found in array road in Block 15 Array 17 with San Joaquin kit fox scat in middle of pile
Eared Grebe *Podiceps nigricollis*	Presumed predation	Found floating in Dust Control Pond; head injured, top of cranium missing.
November 2013		
Mourning Dove *Zenaida macroura*	Unknown	Feathers found in Block 7
Horned Lark *Eremophila alpestris*	Unknown	Approximately 100 body feathers found in Block 11 Array 16
American Coot *Fulica americana*	Unknown	Block 15 Array 18
Common Raven *Corvus corax*	Unknown	25-30 feathers found scattered just south of north perimeter road in Block 11
Rock Pigeon *Columba livia*	Unknown	Feather pile found scattered throughout quadrant A in Block 11 Array 7
December 2013		
Burrowing Owl *Athene cunicularia*	Predation	Headless and wingless carcass found on top of inverter at vault in Block 11 Array 13
Rock Pigeon *Columba livia*	Predation	Bloody feathers found in Block 11 perimeter road at pole 63

Species	Cause of Death	Notes
Rock Pigeon *Columba livia*	Unknown	Feathers found in Block 11 Array 1
Common Raven *Corvus corax*	Presumed predation	Feathers found in Block 12 Array 21;
Common Raven *Corvus corax*	Unknown	Wing and feathers found in Block 14 laydown

Appendix B – Other Wildlife Fatalities

Other wildlife mortality detected at the Topaz Solar Farms, January through December 2013.

Species	Cause of Death	Notes
January 2013		
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Found in road at Well Road and Road B intersection
Deer Mouse *Peromyscus maniculatus*	Moving materials	Found in Secure Laydown; crushed
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Found at Block 4 access road; vehicle strike
Desert Cottontail *Sylvilagus auduboni*	Equipment strike	Found in Block 8 east against tilt stack; fork lift appeared to have pierced abdominal area
California Ground Squirrel *Spermophilus beecheyi*	Predation	Found in Block 9 Array 5; predation from raptor
Northern Pacific Rattlesnake *Crotalus oreganus oreganus*	Equipment strike	Found at Cochrane demolition; injured during excavation, broken back, posterior end
Northern Pacific Rattlesnake *Crotalus oreganus oreganus*	Equipment strike	Block 10 Cochrane demolition site, killed by equipment
Desert Cottontail *Sylvilagus auduboni*	Equipment strike	Dead rabbit found at Cochrane pond; killed by excavation
Desert Cottontail *Sylvilagus auduboni*	Equipment strike	Dead rabbit found at Cochrane pond; killed by excavation
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Killed at excavation site at Cochrane
California Ground Squirrel *Spermophilus beecheyi*	Equipment strike	Casualty of excavation at Cochrane demolition
Desert Cottontail *Sylvilagus auduboni*	Unknown	Found at irrigation pond at Cochrane; hind feet and head all that remained
California Ground Squirrel *Spermophilus beecheyi*	Unknown	Found dead at Helios Way trench northeast of Guard Shack
California Ground Squirrel *Spermophilus beecheyi*	Presumed predation	Found tail of squirrel and fresh coyote prints in Block 7 Array 19
February 2013		
Deer Mouse *Peromyscus maniculatus*	Unknown	Found at Topaz Office
California Ground Squirrel *Spermophilus beecheyi*	Presumed predation	Found in Block 9 along access road; common raven observed picking at it; did not appear to be hit by equipment; possible predation.
California Ground Squirrel *Spermophilus beecheyi*	Unknown	Found at Guard Shack
California Ground Squirrel *Spermophilus beecheyi*	Presumed predation	Found in Block 9 Array 7; appeared to be a raptor kill; only fur/skin left, no body cavity
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Killed while trenching in Block 8 Array 16; long slice through length of body
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Found at the bottom of trench in Block 8 east Array 22; killed by trencher.
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Squirrel found on Tracy Lane; vehicle strike

Species	Cause of Death	Notes
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Found in CSI Laydown Yard; appeared to be vehicle strike
California Ground Squirrel *Spermophilus beecheyi*	Equipment strike	Found in Block 7 Array 22; appeared to have been struck by something on its back
Deer Mouse *Peromyscus maniculatus*	Unknown	Found in Block 5 recycling yard; juvenile
Deer Mouse *Peromyscus maniculatus*	Unknown	Found in Block 5 recycling yard; juvenile
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Found on Road A at Dust Control Pond; most likely vehicle strike
March 2013		
Deer Mouse *Peromyscus maniculatus*	Entrapment	Found at bottom of auger hole for Powerline pole #94
Western Spadefoot Toad *Spea hammondii*	Vehicle strike	Found on road in Block 10 Array 6; run over by forklift
Deer Mouse *Peromyscus maniculatus*	Entrapment	Fell into Powerline Pole 94 augur hole
Deer Mouse *Peromyscus maniculatus*	Entrapment	Fell into Powerline Pole 110 augur hole
Deer Mouse *Peromyscus maniculatus*	Unknown	Found dead inside PCVS3 shelter in Block 5; appeared crushed
Western Toad *Bufo boreas*	Vehicle strike	Found at Road B; vehicle strike
Black Tailed Jackrabbit *Lepus californicus*	Unknown	One newborn dead at Block 21 Grain Silo
Black Tailed Jackrabbit *Lepus californicus*	Equipment strike	Adult crushed due to demolition activities at Block 21 Grain Silo
Desert Cottontail *Sylvilagus auduboni*	Moving materials	Baby cottontail killed while pallets were being moved in Block 8 Array 18
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Found in Block 9 road
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Found in Block 15 west perimeter road
Deer Mouse *Peromyscus maniculatus*	Unknown	Found dead in Block 7 PCVS18
Side-blotched lizard *Uta stansburiana*	Moving materials	Found under pallet pile in Block 10 Array 8
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Found on Helios Way
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Found dead in perimeter road of Block 15
Valley Pocket Gopher *Thomomys bottae*	Unknown	Found dead juvenile gopher in Block 8 Array 21 road
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Found on Block 14 access road
April 2013		
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Found on Road A
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Found floating in Dust Control Pond

Species	Cause of Death	Notes
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Helios Way
California King Snake *Lampropeltis getula californiae*	Vehicle strike	Juvenile; Block 9/10 access road
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Block 10 Array 9
Heermann's Kangaroo Rat *Dipodomys heermanni*	Drowning	Fell into vehicle wheel wash water tank
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Fell into vehicle wheel wash water tank
Deer Mouse *Peromyscus maniculatus*	Vehicle strike	Mechanics yard
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Southeast Block 15
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Found dead on Helios Way
Northern Pacific Rattlesnake *Crotalus oreganus oreganus*	Vehicle strike	Block 14 laydown
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Block 14
May 2013		
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Block 9 "S" Road
Pacific Gopher Snake *Pituophis catenifer catenifer*	Predation	Being eaten by a common raven south of Road A
California Ground Squirrel *Spermophilus beecheyi*	Predation	Carcass partially eaten in Block 8 Array 14
Desert Cottontail *Sylvilagus auduboni*	Unknown	Ravens picking at carcass in Block 10
Mouse Species unidentified	Construction activities	Found where post pounding was occurring in Block 15 Array 15
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Helios Way
Heermann's Kangaroo Rat *Dipodomys heermanni*	Drowning	Fell into vehicle wheel wash water tank
Desert Cottontail *Sylvilagus auduboni*	Crushed when moving materials	Juvenile in Block 11 laydown
Desert Cottontail *Sylvilagus auduboni*	Crushed when moving materials	Juvenile in Block 11 laydown
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Move-on near fueling area
Heermann's Kangaroo Rat *Dipodomys heermanni*	Drowning	Fell into vehicle wheel wash water tank
Heermann's Kangaroo Rat *Dipodomys heermanni*	Drowning	Fell into vehicle wheel wash water tank
Heermann's Kangaroo Rat *Dipodomys heermanni*	Drowning	Fell into vehicle wheel wash water tank
Desert Cottontail *Sylvilagus auduboni*	Drowning	Fell into vehicle wheel wash water tank

Species	Cause of Death	Notes
California Ground Squirrel *Spermophilus beecheyi*	Predation	Found dead inside Dust Control Pond fence; not a fatality of the Dust Control Pond, had been dropped there by ravens
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Found in hand wash container of a port-o-john in Block 14 east
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Found in hand wash container of a port-o-john in Block 14 east
June 2013		
Western Toad *Bufo boreas*	Unknown	Found at hydration area at CSI laydown; adult
Opossum *Didelphis virginiana*	Unknown	Found under bus on drip pan in Move-on
Desert Cottontail *Sylvilagus auduboni*	Unknown	Juvenile found near perimeter fence of Dust Control Pond (not in pond); no obvious injury
Heermann's Kangaroo Rat *Dipodomys heermanni*	Vehicle strike	Helios Way
July 2013		
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle Strike	Block 11
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Removed ground squirrel carcass from Dust Control Pond
California Ground Squirrel *Spermophilus beecheyi*	Vehicle Strike	Found in middle of the east perimeter road in Block 14 Array 6
California Ground Squirrel *Spermophilus beecheyi*	Predation	Found in Block 14 Array 19; head, front feet, and half of abdomen removed
August 2013		
Domestic Cat *Felis catus*	Unknown	Found under metal conex/storage container in secure laydown. Appears to have been deceased for months as only skeleton, dentition, and fur remained. No soft tissue. Secure Laydown
Bat Species unidentified	Unknown	Bat found in Block 15 Array 5 after it was removed from a transport container; container was picked up by driver at the Port of Los Angeles
September 2013		
Snake Species unidentified	Presumed equipment strike	Block 12 Array 15
October 2013		
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Found in Block 12 Array 18
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Removed from Dust Control Pond

Species	Cause of Death	Notes
American Coot *Fulica americana*	Unknown	Pile feathers in middle array road in Block 15 Array 17; San Joaquin kit fox scat in middle of feather pile
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Dead on Block 12 west road
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Young juvenile; found on Blocks 9/10 split road; minor cut along lower tail, slightly flattened throat near trachea
Desert Cottontail *Sylvilagus auduboni*	Unknown	Found in Block 10 Array 21; juvenile
Northern Pacific Rattlesnake *Crotalus oreganus oreganus*	Likely vehicle strike	Found at Arco Building demolition site
Pacific Gopher Snake *Pituophis catenifer catenifer*	Likely vehicle strike	Block 14 perimeter road
November 2013		
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle Strike	Road A
December 2013		
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Found in the Dust Control Pond

Appendix C – Topaz Solar Farms 2013 Bird List

BIRDS RECORDED AT TOPAZ PROJECT SITE: 2010-2013	**SEASONAL OCCURRENCE AT PROJECT SITE: 2010-2013** **SPRING**: MARCH through MAY **SUMMER**: JUNE through JULY **FALL:** AUGUST through NOVEMBER **WINTER**: DECEMBER through FEBRUARY				**STATUS in the CARRIZO PLAIN** **M** = Migrant **R** = Resident **W** = Winter Visitor **SB** = Summer Breeder	**BREEDING: 2013** **C**=Confirmed **S**=Suspected	**OBSERVED: 2013**	**LOCATION CODES: 2013** **KR** = Kuhnle Residence, northern edge of Section 19 (35.396031°, -120.085892°) **DCP** = Topaz Dust Control Pond, Section 20. **LJ** = Lowery Jopling Property (DFG Mitigation Land), Section 33, (35.358135°, -120049684°) **Cochrane** = Cochrane Property, Section 28, Block 10 (35.370935°, -120.049684)
Species (2010-2013)	**Spring**	**Summer**	**Fall**	**Winter**	**Status**	**Breeding**	**2013**	**Date and Location**
GEESE & DUCKS								
Ross's Goose				**X**	**M, W**		**X**	DCP: 08JAN2013
Canada Goose				**X**	**M, W**		**X**	Flock flew over project site: 27JAN2013
Gadwall	**X**				**M, W**			
Mallard	**X**				**M, W**		**X**	DCP: 02MAY2013.
Cinnamon Teal	**X**		**X**	**X**	**M, W**		**X**	DCP: 22FEB, 08AUG, 17AUG2013
teal sp.			**X**				**X**	DCP: 08AUG2013
Northern Shoveler	**X**	**X**	**X**	**X**	**M, W**		**X**	DCP: 18MAR, , 31JUL, 02OCT, 10-11NOV and 21DEC2013
Green-winged Teal				**X**	**M, W**		**X**	Block 11: 05DEC2013; DCP: 08DEC and 21DEC2013
Bufflehead				**X**	**M, W**		**X**	DCP: 19JAN2013
Hooded Merganser			**X**		**M, W**		**X**	DCP: 15NOV2013
Ruddy Duck	**X**				**M, W**		**X**	DCP, 15MAR2013
duck sp.			**X**		**M, W**		**X**	10 flew over site in V formation: 18OCT2013
QUAIL								
California Quail	**X**				**R**		**X**	Block 10: 14MAR2013
GREBES								
Eared Grebe			**X**	**X**	**M**		**X**	DCP: 03JAN, 28SEP13, WK; [03, 04, 06, 08, 09 and 10OCT, then found dead in DCP and collected 16OCT2013]
Western Grebe			**X**		**M**		**X**	DCP: 23AUG2013
HERONS, BITTERN & ALLIES								
Great Blue Heron	**X**	**X**	**X**		**M**		**X**	DCP: 25FEB, 02MAY, 09AUG, 21AUG and 02OCT2013
Great Egret	**X**		**X**		**M**		**X**	DCP: 02MAY and 16MAY2013; fly-over southeast of Blocks 11-14, all 2013
Snowy Egret	**X**		**X**		**M**		**X**	Along 12 access road: 04OCT2013; Block 12 east of Pronghorn Plains Road: 04OCT2013
Green Heron	**X**				**M**		**X**	DCP: 30APR and 02MAY2013
IBIS								
White-faced Ibis	**X**		**X**		**M**		**X**	DCP: 14SEP2013
NEW WORLD VULTURES								
Turkey Vulture	**X**	**X**	**X**	**X**	**R**		**X**	
OSPREYS								
Osprey	**X**		**X**		**M**		**X**	South of Section 35: 06SEP2013
HAWKS, KITES & EAGLES								
White-tailed Kite	**X**				**M**		**X**	Southwest of LJ: 10MAR2013
Bald Eagle				**X**	**W**		**X**	[Various locations between 18DEC2012—05FEB2013]
Northern Harrier	**X**	**X**	**X**	**X**	**M, W**		**X**	Section 14: 14MAY2013; South of Block 5: 27SEP2013
Sharp-shinned Hawk			**X**	**X**	**M, W**		**X**	Substation: 07DEC2013
Cooper's Hawk			**X**	**X**	**M, W**		**X**	LJ: 06SEP, 24SEP, 18OCT, 14NOV2013; Section 5, 13DEC2013
Red-shouldered Hawk		**X**	**X**		**M**		**X**	LJ: 24JUL2013
Swainson's Hawk	**X**		**X**		**M**		**X**	Fly-over Block 9/10: 27SEP2013
Red-tailed Hawk	**X**	**X**	**X**	**X**	**M, R, SB**	**C**	**X**	
Ferruginous Hawk	**X**	**X**	**X**	**X**	**M, W**		**X**	Section 8: 17SEP2013
Rough-legged Hawk			**X**	**X**	**M, W**			
Golden Eagle	**X**		**X**	**X**	**R**		**X**	
RAILS, GALLINULES & COOTS								

BIRDS RECORDED AT TOPAZ PROJECT SITE: 2010-2013	**SEASONAL OCCURRENCE AT PROJECT SITE: 2010-2013**				**STATUS in the CARRIZO PLAIN**	**BREEDING: 2013**	**OBSERVED: 2013**	**LOCATION CODES: 2013**
Virginia Rail			X		M		X	Block 11: 09SEP2013
Sora			X		M		X	1 juv found dead along Helios Way and collected: 08OCT2013
American Coot			X		R		X	Block 15, Array 17: 10OCT13; a bird in Block 15: 16NOV was found dead the following day, 17NOV2013
STILTS & AVOCETS								
American Avocet	X	X		X	R		X	DCP: 07JAN and 7JUN2013
Black-necked Stilt	X		X		M		X	DCP: 19MAY and 15AUG2013
PLOVERS								
Killdeer	X	X	X	X	R		X	DCP: 31JUL2013
Mountain Plover	X			X	W		X	Section 35: 08DEC2013
SANDPIPERS & PHALAROPES								
Spotted Sandpiper	X	X	X		M		X	DCP: 04MAY, 09MAY, 19MAY, 23JUL, 31JUL, 01AUG, 02AUG, 03AUG, and 13AUG2013
Greater Yellowlegs		X	X		M		X	DCP: 20JUL2013; Cochrane: 26JUL2013; fly-over Block 11: 13SEP2013; fly-over Block 10: 24OCT2013
Willet			X		M		X	Block 15: 04AUG2013
Whimbrel	X		X		M			
Long-billed Curlew	X	X	X	X	M		X	
Least Sandpiper			X		M		X	Block 11: 13SEP2013
Western Sandpiper		X	X		M		X	Block 3: 20AUG2013; DCP, 21AUG2013; Block 11: 07OCT2013
Long-billed Dowitcher	X	X		X	M		X	Section 28: 8MAY2013; DCP: 22JUL2013
dowitcher sp.		X			M			
Wilson's Phalarope	X	X	X		M		X	DCP: 20JUL and 03AUG2013
Red-necked Phalarope			X		M		X	DCP: 03AUG, 09-11AUG, 21-22AUG, 23-24AUG and 27AUG2013
sandpiper sp.			X		M		X	Block 3: 20AUG2013; Block 12: 13DEC2013
GULLS								
California Gull			X		M		X	Block 10: 19AUG2013
gull sp.			X		M		X	Block 11: 09OCT2013
PIGEONS & DOVES								
Rock Pigeon	X	X	X	X	R	C	X	
Eurasian Collared Dove	X	X	X	X	R		X	KR: May 2013; Block 9, Array 25: 07DEC2013
Mourning Dove	X	X	X	X	R	C	X	
CUCKOOS & ALLIES								
Greater Roadrunner	X	X	X		R		X	Helios Way: 04JUL2013; Block 4: 31JUL2013; Tenplex: 16AUG2013; Tracy Ln: 20AUG2013; Block 4: 22AUG2013; Access Rd A: 29AUG2013; DCP, 30AUG2013; Block 5: 16OCT2013
BARN OWLS								
Barn Owl	X	X	X	X	R	C	X	Multiple observations in 2013; Nested inside Arco Building: 2013--2 nestlings there: 28MAY2013; and 2 juvs with 2 adults: 10JUL2013
TYPICAL OWLS								
Great Horned Owl		X			R		X	LJ: spring 2013
Burrowing Owl	X	X	X	X	M, R, SB	C	X	
Short-eared Owl	X			X	W			
SWIFTS								
Vaux's Swift			X		M		X	Hwy 58 at Helios Way: 19SEP2013
White-throated Swift	X			X	R, SB		X	Section 34: 15JAN2013; Fly-over Block 7: 23MAY2013
HUMMINGBIRDS								
Anna's Hummingbird		X	X		R, SB		X	LJ: 20SEP and 03OCT2013
Costa's Hummingbird		X	X		M			
selasphorus sp. (Rufous/Allen's)			X		M		X	KR: 20AUG2013
WOODPECKERS								
Red-breasted Sapsucker			X	X	W		X	LJ: 01NOV *thru* 06FEB2013; KR: 19NOV2013
Nuttall's Woodpecker			X	X	R		X	LJ: 06FEB13
Northern Flicker			X	X	R		X	LJ: 10OCT2013; LJ: 16OCT2013; Block 16, 11NOV2013

BIRDS RECORDED AT TOPAZ PROJECT SITE: 2010-2013	SEASONAL OCCURRENCE AT PROJECT SITE: 2010-2013				STATUS in the CARRIZO PLAIN	BREEDING: 2013	OBSERVED: 2013	LOCATION CODES: 2013
FALCONS								
American Kestrel	X	X	X	X	R		X	
Merlin	X		X	X	W		X	Block 15: 19SEP2013
Peregrine Falcon	X	X	X	X	R		X	LJ: 07MAR2013; Tower Road:22JUL2013
Prairie Falcon	X	X	X	X	R, SB		X	
FLYCATCHERS								
Western Wood-Pewee	X				M		X	LJ, 8-9MAY and 22-23MAY2013
Willow Flycatcher	X	X			M		X	KR: 15MA20Y13; LJ: 20-21MAY2013
Hammond's Flycatcher	X				M		X	LJ: 25APR2013
Pacific-slope Flycatcher	X		X		M		X	LJ: 25APR, 10MAY, and 17SEP2013
Black Phoebe	X	X	X	X	R	S	X	
Say's Phoebe	X	X	X	X	R	C	X	Successful nest at LJ: 07MAY2013
Ash-throated Flycatcher	X	X	X		SB		X	
Cassin's Kingbird	X	X	X		SB	C	X	Nest attempt at LJ: 2013
Western Kingbird	X	X	X		SB	S	X	
SHIRIKE								
Loggerhead Shrike	X	X	X	X	R, SB	C	X	
VIREOS								
Cassin's Vireo	X				M		X	LJ: 25APR2013
Warbling Vireo	X		X		M		X	LJ: 25APR13, 14MAY and 06SEP2013; 1 at Cochrane: 16SEP2013
CROWS & JAYS								
American Crow	X	X	X	X	R, SB	C	X	Nest attempt at LJ: spring 2013
Common Raven	X	X	X	X	R, SB	C	X	Block 11 east of Tracy: 04OCT2013
LARKS								
Horned Lark	X	X	X	X	R, SB	C	X	
SWALLOWS								
Tree Swallow			X	X	M		X	
Violet-green Swallow	X				M		X	Fly-over Block 5: 25MAY2013
Northern Rough-winged Swallow	X		X		M		X	LJ: 5MAR2013; Fly-over: 17SEP2013
Bank Swallow			X		M		X	Fly-over Block 15: 03SEP2013
Cliff Swallow	X	X			M		X	Block 8: 19JUN2013; DCP: 08JUL13
Barn Swallow	X	X	X		M		X	Cochrane: 30APR2013; Section 33: 24JUL13; DCP, 19SEP2013; LJ: 20SEP and 27SEP2013; Fly-over project site: 03OCT2013
TITMICE & CHICKADEES								
Oak Titmouse			X		R			
NUTHATCHES								
White-breasted Nuthatch			X		M, W		X	LJ: 19SEP2013; [1 at LJ, 20SEP, 26SEP and 03OCT2013]
KINGLETS								
Ruby-crowned Kinglet	X		X	X	M, W		X	Multiple fall and winter observations at both LJ and Cochrane; late date at Cochrane: 30APR2013

Quarterly Report

COA 62 Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan Quarterly Report

February 13, 2013

Discussion

This report has been prepared to address the reporting requirements for Condition of Approval (COA) 62 Bird Monitoring and Avoidance Plan. The BMAP report was prepared to include bats and the title revised to the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP).

In response to COA 62, the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP) has been prepared, which further describes the approach to implementing the condition requirements.

COA 62 requires quarterly and annual reports. Quarterly reports are required during construction and for three years following the beginning of the solar farm operation.

Following the completion of the fourth quarter of monitoring the biologist shall prepare an annual report that summarizes the year's data, analyzes any project-related bird fatalities or injuries detected, and provides recommendations (in consultation with the County) for future monitoring and any adaptive management actions needed.

Quarterly Reportable Items

COA 62 ABMP requires quarterly reports describing the dates, durations, and results of monitoring and data collection. The quarterly reports shall provide a detailed description of any project-related bird or wildlife deaths or injuries detected during the monitoring study or at any other time.

Report Data

Attached is the quarterly report prepared by Althouse & Meade (COA 62 and ABPP Quarterly Monitoring Report by Althouse & Meade February 13, 2013).

Topaz Solar Farm
Avian and Bat Protection Plan
and
Bird Monitoring and Avoidance Plan

Fourth Quarterly/First Annual Report for 2012

This Fourth Quarterly/First Annual Report provides information pertinent to the reporting obligations regarding implementation of various tasks required by the Topaz Solar Farm Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (Althouse and Meade, Inc. June 2011). The Avian and Bat Protection Plan (ABPP) and Bird Monitoring and Avoidance Plan (BMAP) are requirements of County of San Luis Obispo Conditions of Approval (COA) 61 and 62, and were prepared in consultation with USFWS and CDFW. Section 5.5 of the ABPP/BMAP document requires quarterly and annual reports to be submitted to the County of San Luis Obispo, U.S. Fish and Wildlife Service (USFW) and the California Department of Fish and Wildlife (CDFW). This Fourth Quarterly Report has been augmented to satisfy requirements of the annual reporting obligation, and thus constitutes the first annual report for the Topaz Solar Farms ABPP/BMAP. Information provided spans the period from January 1 through December 31, 2012.

List of Figures

1.0 Avian and Bat Protection Plan

The ABPP monitoring program compiles general information on bird and bat interactions, injuries and mortality at the Topaz Solar Farm. During construction phases of the project this task is completed by the project biologists, as part of routine daily biological monitoring. Data reported for the Bird Monitoring and Avoidance Plan, which provides detailed information on bird use and bird mortality at the project site, is presented below in Section 2.0.

1.1 Bird Surveys

General bird surveys are conducted on and around the project site on a daily basis throughout the year by project biologists. Species lists are generated and maintained, and interesting bird observations are highlighted. A list of 113 bird species observed on and near the project site is included as Exhibit 3.

1.2 Nesting Activity

All nests and nest starts identified during the 2012 nesting season were documented. The month each nest and nest start were found are shown in Figure 1. A total of 9 bird species were documented nesting in or near the 2012 work areas (Table 1). Other species nesting in offsite mitigation lands or future project lands are not included in this tally. Burrowing owl was the only special concern species nesting on or near the project. Nesting was documented spanning the months of March through July, with fledgling burrowing owls observed into August. The peak nesting period, in terms of number of nests and number of species nesting was late April through May. The horned lark was the most abundant nesting species, with over 50 nests and nest starts identified in May 2012.

TABLE 1. 2012 NESTING DATA BY MONTH. The number of nests detected each month is listed for 9 species between March and July.

Species	March	April	May	June	July
Barn Owl	0	0	0	1	0
Burrowing Owl	1	1	1	1	1
Common Raven	1	6	2	4	2
European Starling	2	2	1	0	0
Horned Lark	0	16	51	8	0
House Finch	2	5	3	0	0
Mourning Dove	1	1	0	0	0
Western Meadowlark	0	13	2	0	0

Species	March	April	May	June	July
Say's Phoebe	1	0	0	0	0

Horned larks nest on the ground in a woven grass cup, often placed in a small depression. They prefer patchy short-grass conditions with bare spots. Array areas with newly vegetated ground provided a preferred nesting substrate. Although specific data was not compiled, our observations suggest horned lark nesting density was higher in array areas than in undisturbed grassland. Nest success was observed to be low in the array areas, with a high rate of predation by ravens and other wildlife. When a nest was predated, surveys of the vicinity often showed attempts to re-nest close by. Horned larks do not re-use nests. No prevention methods were utilized to keep horned larks from nesting in the arrays other than removal of nest starts. Detection of nest starts required intensive daily survey efforts, and nests with eggs or chicks were often found and left in place.

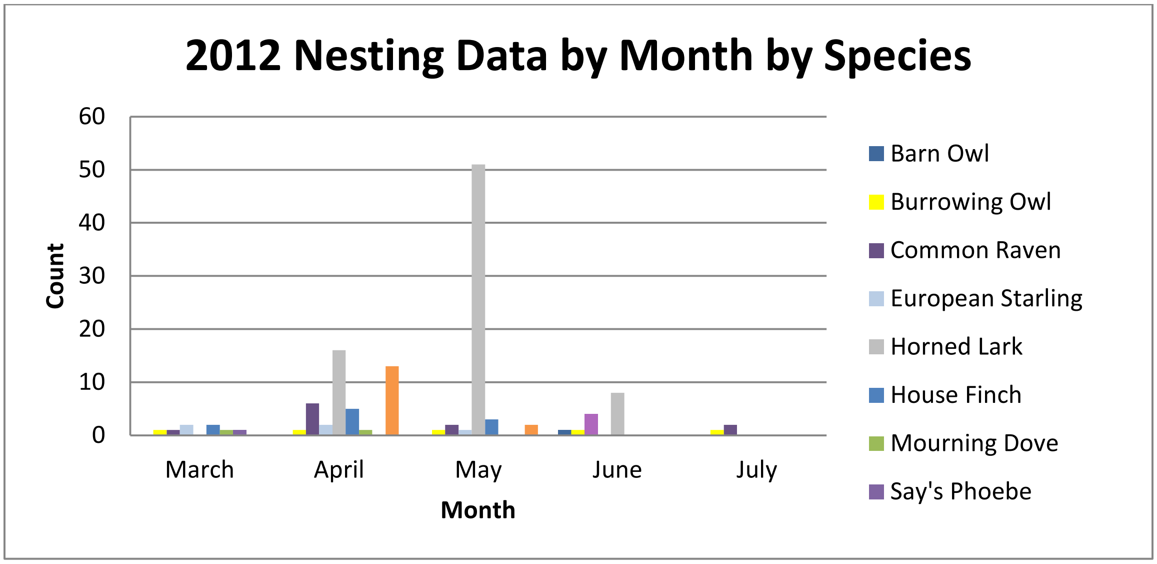
Western meadowlarks nest on the ground in taller grass habitats. All meadowlark nests identified were in future work areas containing tall grasses with abundant mustards. Mowing of tall grass fields prior to nesting activity was conducted in limited areas to prevent meadowlark nesting.

House finches nested or attempted to nest on construction equipment and materials throughout the project site. Preferred nesting areas were in small pieces of equipment, gaps in spools, and openings in cardboard boxes. Flashing tape and bird netting were used to prevent house finch nesting on materials and equipment. Both of these methods were effective.

Ravens nested on power poles within and around the project. They also attempted to nest on heavy equipment and on abandoned windmills in future work areas. Nesting materials were removed daily from some nest sites to prevent nesting. For equipment, removing nest starts and moving the equipment to a new location solved the problem. At one medium-voltage power pole within the project the nest start was removed on several occasions but eventually the ravens were allowed to nest on the pole. Unfortunately one chick died as a result of entanglement in nesting materials.

Burrowing owls nested in several locations immediately adjacent to the project. One nest attempt along Helios Way failed when one of the adults died. One nest northeast of Block 6 was observed to have 7 chicks in June 2012. Biologists observed a prairie falcon kill one of the burrowing owl chicks as it stood with the cohort at the burrow entrance. Survival of the remaining chicks was not known, but all remaining were fledged in August 2012. A third nest located west of the project successfully fledged, but the number of fledglings was not determined.

FIGURE 1. 2012 NESTING DATA BY MONTH.



1.3 Avian and other Wildlife Mortality

General biological monitoring of the Topaz work areas documented bird, bat and other wildlife mortality. All mortality identified on site from January through December 2012 is provided in Table 2. Cause of death is reported when known.

TABLE 2. BIRD AND OTHER WILDLIFE MORTALITY. Bird and other wildlife mortality detected at the Topaz Solar Farm, January through December 2012.

Species	Cause of Death	Notes
January 2012		
Horned Lark *Eremophila alpestris*	Unknown	One carcass found under powerlines along Tower Road
California Vole *Microtus californicus*	Unknown	One carcass removed from an open fence post hole
February 2012		
Mourning Dove *Zenaida macroura*	Raptor predation	One carcass found 200 yards north of Hwy 58 on Helios Way
Pacific Gopher Snake *Pituophis catenifer catenifer*	Unknown	One carcass found in grass east of Phase 1 North Array
Pacific Gopher Snake *Pituophis catenifer catenifer*	Construction activities	Hit by road grader in dust control pond area
Western Meadowlark *Sturnella neglecta*	Raptor predation	One carcass found on Tower Road
Horned Lark *Eremophila alpestris*	Predation	One carcass found in the secure laydown area
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Phase 1 North Array

Species	Cause of Death	Notes
March 2012		
Botta's Pocket Gopher *Thomomys bottae*	Unknown	One carcass found in Phase 1 South Array
Horned Lark *Eremophila alpestris*	Predation	Remains found in Phase 1 North Array
House Finch *Carpodacus mexicanus*	Predation	Three carcasses removed from the Helios laydown; house-cat is probable predator
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass found in Block 3
Savannah Sparrow *Passerculus sandwichensis*	Entanglement/Predation	One carcass caught in exclusion net and partially eaten in Helios laydown area
Heermann's Kangaroo Rat *Dipodomys heermanni*	Drowning	One carcass found in the Helios wheel wash
April 2012		
Unidentified Mice	Drowning	Two carcasses found in the Helios wheel wash
Unidentified Mice	Unknown	Two carcasses found under materials stack in Phase 1 South Array
Horned Lark *Eremophila alpestris*	Unknown	One carcass found in Phase 1 South Array
Pacific Gopher Snake *Pituophis catenifer catenifer*	Construction activities	Killed by equipment moving materials
Pacific Gopher Snake *Pituophis catenifer catenifer*	Entanglement	One carcass found in bird abatement netting in the Helios laydown area
Savannah Sparrow *Passerculus sandwichensis*	Entanglement	One carcass found in bird netting in the Helios laydown area
Botta's Pocket Gopher *Thomomys bottae*	Unknown	Two carcasses found in open fence post holes
Heermann's Kangaroo Rat *Dipodomys heermanni*	Unknown	One carcass found in open fence post hole
May 2012		
Savannah Sparrow *Passerculus sandwichensis*	Predation	Two carcasses found in Phase 1 South Array; house-cat is probable predator
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass found in trench in Phase 1 North Array
Deer Mouse *Peromyscus maniculatus*	Drowning	Two carcasses found in dust control pond well head
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Unknown	One carcass found in Phase 1 North Array
California Ground Squirrel *Spermophilus beecheyi*	Predation	One carcass found near dust control pond
California Ground Squirrel *Spermophilus beecheyi*	Predation	One carcass found in Block 3

Species	Cause of Death	Notes
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Five carcasses removed from Helios Way
Wilson's Phalarope *Phalaropus tricolor*	Unknown; either drowning or raptor predation	One carcass found in dust control pond
Northern Pacific Rattlesnake *Crotalus oreganus oreganus*	Vehicle strike	One juvenile found in Phase 1 North Array
Horned Lark *Eremophila alpestris*	Unknown	One carcass with no visible wounds on Helios Way
Horned Lark *Eremophila alpestris*	Raptor predation	One carcass found outside Block 3 fence
Horned Lark *Eremophila alpestris*	Raptor predation	One carcass found in Block 2
House Finch *Carpodacus mexicanus*	Construction activities	One egg crushed during accidental exposure of nest built in cable roll; nest subsequently abandoned
June 2012		
Horned Lark *Eremophila alpestris*	Predation	One carcass found in Phase 1 South Array
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass found in Phase 1 South Array
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass found in Block 2
House Finch *Carpodacus mexicanus*	Predation	On material stacks. Two eggs and two dead chicks. Nest abandoned.
Unidentified Mice	Drowning	Two carcasses found in dust control pond well head
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Three carcasses removed from dust control pond
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Access Road A
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	One carcass removed from Helios laydown entrance
Pacific Gopher Snake *Pituophis catenifer catenifer*	Construction activities	One killed during ground preparation work in Block 1
Pacific Gopher Snake *Pituophis catenifer catenifer*	Construction activities	Two juveniles killed during ground preparation work in Block 2
Brewer's Blackbird *Euphagus cyanocephalus*	Injury	One female flew into the side of a concrete vault
July 2012		
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Drowning	11 carcasses were removed from the dust control pond in July
Deer Mouse *Peromyscus maniculatus*	Construction activities	2 dead mice were removed from a work area, likely crushed by moving materials
Horned Lark *Eremophila alpestris*	Unknown	One carcass was removed from an array area

Species	Cause of Death	Notes
European Starling *Sturnus vulgaris*	Unknown	Carcass found near a work area perimeter fence, no apparent injuries
Western Bluebird *Sialia mexicana*	Probable vehicle strike on Highway 58 off site, carried onto site by car.	Juvenile found near cars in parking lot
Common Raven *Corvus corax*	Entanglement in nesting material	Foot of nestling was entangled in nesting material, bird died when it tried to fledge.
August 2012		
Deer Mouse *Peromyscus maniculatus*	Vehicle strike	2 carcasses were removed from project roads in August
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Five carcasses removed from dust control pond
California Ground Squirrel *Spermophilus beecheyi*	Unknown	Two carcasses were removed from work areas in August
Violet-Green Swallow *Tachycineta thalassina*	Drowning	Juvenile removed alive from dust control pond; died shortly thereafter
Horned Lark *Eremophila alpestris*	Unknown	One carcass removed from array area in Block 2
Desert Cottontail *Sylvilagus auduboni*	Abandoned by parents	3 juveniles found under a pallet, two were relocated, third was dead
Cooper's Hawk *Accipiter cooperii*	Unknown	Desiccated carcass found in arrays of Block 6. CDFG and USFWS notified. Carcass was transferred to CDFG Jan 10, 2013.
September 2012		
Virginia Rail *Rallus limicola*	Collision with fence	Rail collected dead in parking area at base of chain link fence with obvious collision wound
California Ground Squirrel *Spermophilus beecheyi*	Drowning	Two carcasses were removed from the dust control pond in September
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	Two carcasses removed from work area in Block 5
Brewer's Blackbird *Euphagus cyanocephalus*	Unknown; possible entrapment or crushing by moving materials	Four carcasses were removed from between materials boxes in a laydown yard.
Botta's Pocket Gopher *Thomomys bottae*	Unknown; possible failed predation attempt	One carcass was removed from Block 1
Deer Mouse *Peromyscus maniculatus*	Crushed by materials	Reported by workers, mouse died before it could be treated or released
Deer Mouse *Peromyscus maniculatus*	Unknown	One carcass removed from Block 5
Heermann's Kangaroo Rat *Dipodomys heermanii*	Equipment strike	Mortally wounded by heavy equipment
Horned Lark *Eremophila alpestris*	Raptor predation	Reportedly dropped by a raptor, the carcass was removed by biologists
Horned Lark *Eremophila alpestris*	Raptor predation	One carcass with injuries consistent with a failed raptor predation attempt was removed from Block 8

Species	Cause of Death	Notes
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle/equipment strike	2 juvenile gopher snake carcasses were removed from work areas
Desert Cottontail *Sylvilagus audubonii*	Exposure	A juvenile rabbit was removed alive from a trench but died shortly thereafter
Common Raven *Corvus corax*	Unknown	One carcass was removed from Block 1 work area with no apparent injuries
October 2012		
Common Raven *Corvus corax*	Predation	Remains were found in Block 5
Long-billed Curlew *Numenius americanus*	Predation	Carcass found with missing head in trench in Block 1
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle/equipment strike	Mortally wounded on a project road south of Block 4; euthanized by biologists
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Mortally wounded by a forklift in Block 2; euthanized by biologists
Horned Lark *Eremophila alpestris*	Unknown	Carcass removed from Access Road B; no visible injuries present
November 2012		
Horned Lark *Eremophila alpestris*	Unknown	Carcass found in Block 5
Pacific Gopher Snake *Pituophis catenifer catenifer*	Vehicle strike	Juvenile found dead on Access Road B
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Killed by ground-breaking equipment in Block 8 East
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Killed by a trencher in Block 4
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Carcass found on Helios Way
Deer Mouse *Peromyscus maniculatus*	Unknown	Juvenile found dead outside of nest in materials box
Pacific Chorus Frog *Pseudacris regilla*	Equipment strike	One frog euthanized due to injuries from heavy equipment at the Cochrane site
Coyote *Canis latrans*	Unknown	Old carcass observed under debris pile at the Cochrane site
Barn Owl *Tyto alba*	Drowning/Entrapment	Old carcass observed at bottom of well at the Cochrane site
Western Meadowlark *Sturnella neglecta*	Drowning/Entrapment	Old carcass observed at bottom of well at the Cochrane site. Pre-dates project start.
Western Meadowlark *Sturnella neglecta*	Predation	Carcass found in Block 9 West
Desert Cottontail *Sylvilagus audubonii*	Unknown	Carcass found under panels in Block 2
December 2012		

Species	Cause of Death	Notes
Unidentified Mice	Entrapment	Two mice found in backfilled vault
Mourning Dove *Zenaida macroura*	Raptor predation	One carcass removed from surface of module in Block 7. Presumably dropped by raptor.
Mourning Dove *Zenaida macroura*	Predation	One headless carcass removed from the Cochrane site
Horned Lark *Eremophila alpestris*	Predation	One headless carcass removed from Block 1
House Finch *Carpodacus mexicanus*	Unknown	One carcass removed from Block 3
California Ground Squirrel *Spermophilus beecheyi*	Vehicle strike	One carcass removed from Helios Way
California Ground Squirrel *Spermophilus beecheyi*	Equipment strike	One carcass removed from Block 8
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	Two snakes killed by heavy equipment at the Cochrane site
Pacific Gopher Snake *Pituophis catenifer catenifer*	Equipment strike	One carcass removed from Block 9
Western Meadowlark *Sturnella neglecta*	Injury	One carcass removed from Access Road B; bird appears to have flown into a moving vehicle
California King Snake *Lampropeltis getula californiae*	Equipment strike	One carcass removed from Block 9
Desert Cottontail *Sylvilagus auduboni*	Equipment strike	Three carcasses removed from the Cochrane site
Heermann's Kangaroo Rat *Dipodomys heermanni*	Unknown	One carcass found in open fence post hole in Block 8 West
Pacific Chorus Frog *Pseudacris regilla*	Unknown	One carcass removed from a pitfall trap at the Cochrane site

2.0 Bird Monitoring and Avoidance Plan

The BMAP study utilizes avian use surveys and avian fatality surveys to produce a risk index for various project components deemed to be potentially dangerous to birds, including array areas, overhead power lines and energized equipment (substation). Offsite grassland areas were used as reference sites to compare Bird Utilization Rates, Bird Fatality Rates, and ultimately Bird Risk Index. The BMAP study has two primary goals:

Goal 1. Provide Project owners/managers with scientifically-based risk analyses to facilitate implementation of Adaptive Management actions to minimize conflicts between Project components and birds.

Goal 2. Provide a rigorous scientific study of avian use and mortality associated with specific components of an industrial scale photovoltaic solar facility that can be used by wildlife regulators as a planning tool for future solar projects.

To accomplish these goals, the BMAP outlines five Objectives with specific Tasks:

Objective 1. Assess changes in total bird abundance, species composition, and species richness relative to development and operation of the Project compared to undeveloped reference sites;

Task 1.1: Implement Avian Use Surveys.

Task 1.2: Submit quarterly and annual monitoring reports.

Objective 2. Calculate Bird Utilization Rate, Bird Fatality Rate, and Bird Risk Index for three specific Project components (Array Areas, Overhead Power Lines, Substation/Switching Station);

Task 2.1: Implement Avian Fatality Monitoring Surveys, Searcher Efficiency Trials, and Scavenger/Carcass Removal Trials.

Task 2.2: Run calculations on survey data according to methods in Section 5.4.

Task 2.3: Submit quarterly and annual monitoring reports.

Objective 3. Conduct risk assessment analyses for each Project component based on calculated Bird Utilization Rate, Bird Fatality Rate, and Bird Risk Index;

Task 3.1: Prepare a written analysis of survey data and calculated Bird Risk Index for each Project component to be included in the annual report.

Objective 4. Inform TSF facility managers of Adaptive Management requirements when Bird Risk Index and/or Bird Fatality Rate indicates significance thresholds for avian mortality have been reached (refer to Section 6.0);

Task 4.1: Submit quarterly and annual monitoring reports.

Objective 5. Prepare a scientific paper describing the results of avian use surveys and avian fatality monitoring surveys, and the conclusion regarding the risk level that the Project poses for avian resources.

Task 5.1: Within one year of completion of the study data collection, prepare and submit a scientific paper to the County of San Luis Obispo.

2.1 Discussion regarding Year 1 Data

This Fourth Quarterly/First Annual Report of the ABPP/BMAP provides preliminary data collected for Objectives 1, 2 and 3 (Sections 2.2, 2.3 and 2.5, below). The data is considered preliminary for Year 1 since the pace of construction did not facilitate a large number of Avian Use Surveys or Avian Fatality Surveys to be completed in Array Area, Overhead Powerline and Energized Equipment survey areas, as these areas were not completed with construction until late in the year.

When the BMAP study design was prepared in 2010, prior to start of construction, it was assumed that more completed array areas and powerlines would be available earlier in the year for avian surveys. Therefore, the Year 1 annual report was the designated timeframe for establishing significance thresholds on avian mortality levels. The significance thresholds are to be determined in consultation with the U.S. Fish and Wildlife Service, California Department of Fish and Wildlife, and the County of San Luis Obispo, based on Bird Risk Index data.

We propose to modify the significance threshold determination schedule as presented in the BMAP so that data may be collected through 2013 on avian use and avian fatality at project components. Another year of data from completed project components will provide a robust foundation for the Bird Risk Index calculations, which will better inform significance determinations. If this approach is acceptable to the reviewing agencies, the Topaz Solar Farm ABPP/BMAP document will be revised and resubmitted to reflect the changes.

With respect to the proposal to postpose the significance threshold determination, Objective 4 will be reported beginning with the first quarterly report for Year 2, after significance thresholds have been determined. Objective 5 will be completed within one year after completion of the field surveys.

2.2 Avian Use Surveys

Avian Use Surveys commenced in November 2011, prior to the start of construction, to gather baseline data on bird use in the project area. Avian Use Surveys will inform the Bird Utilization Rate calculations (see Section 2.2.1, below). Construction commenced in late November 2011 in a limited footprint, and slowly expanded in area throughout 2012. Avian use surveys were conducted monthly from November 2011 through December 2012, and will continue throughout the construction period and for three years after construction is complete. Each month, 63 randomly selected survey points were completed, for a total of 882 survey points completed as of December 2012. The 63 survey points include 31 inside existing or future array areas, 18 along existing or future overhead power lines, 10 in grassland reference sites and 4 at the substation. At each point, a 10 minute bird use count is conducted within a 50 meter radius of the surveyor.

Avian Use Survey points were selected each month across all six phases of the project and in offsite grassland reference areas (Exhibit 1). Each month, as construction area increased in size, more of the survey points occurred in developed area. Those points located within future project areas that had not been developed at the time of the survey are categorized as Baseline. Baseline condition is similar to Reference site condition in that it is not developed, however it differs in being cropland habitat versus grassland habitat. Therefore, comparison of Baseline with Reference data could provide information regarding Bird Utilization Rate in different habitat types, if desired.

Forty-three bird species were detected during the avian use surveys from November 2011 through December 2012. Thirteen of these species were detected only once. Horned lark was overwhelmingly the most commonly detected species (6848 detections), followed by house finch (1416), savannah sparrow (776), long-billed curlew (604), common raven (565) and mountain bluebird (526).

For reasons outlined above in Section 2.1, the data collected for Avian Use Surveys and the subsequent analyses for Objective 1 are considered preliminary. Sections 2.2.1, 2.2.2 and 2.2.3 outline our preliminary data collected for bird abundance, species composition and species richness.

2.2.1 Preliminary bird abundance

Total bird abundance is compared in Table 3 between Array Area, Overhead Powerline, Energized Equipment, Reference Site and Baseline survey area categories. Bird abundance is calculated as average number of birds observed per Observation Point. Highest bird abundance was for the Baseline category, at 15.85 birds per Observation Point. The Baseline category represents crop stubble fields prior to start of construction. Reference Sites consisting of grassland habitat had an average of 12.19 birds per Observation Point. Completed Array Areas averaged 11.09 birds per Observation Point, Overhead Powerlines averaged 7.95 birds and Energized Equipment averaged 7.0 birds. Preliminary data suggest a reduction in total bird abundance between the Baseline category and the completed Array Area category.

TABLE 3. PRELIMINARY BIRD ABUNDANCE COMPARISON.

Survey Area Category	**Bird Abundance** **(Average # Birds/Observation Point)**
Baseline (Crop Stubble)	15.85
Reference Site (Grassland)	12.19
Overhead Powerline	7.95
Energized Equipment	7.00
Array Area	11.09

2.2.2 Preliminary species richness

Species richness is a measure of the number of different species in a given area. Table 4 lists the total number of species observed within each of the five survey area categories. Baseline Observation Points had 33 species detected, the highest of any of the survey area categories. Grassland Reference Site points had 20 species detected, both Overhead Powerline and Array Area points had 18 species detected, and Energized Equipment had 14 species.

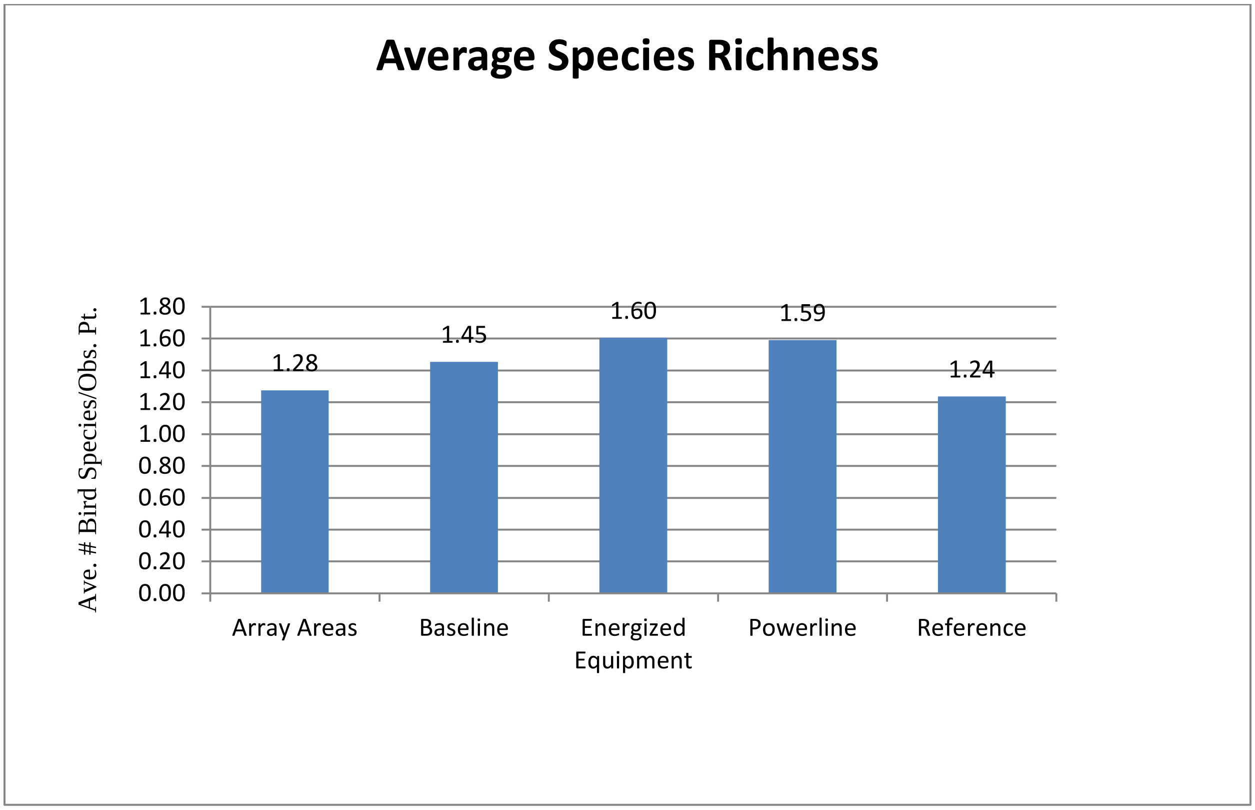
We also compared avian species richness averaged across all Observation Points in each of the five survey area categories from November 2011 through December 2012 (Table 4 and Figure 2). Species richness is markedly similar in each category. Energized Equipment and Overhead Powerlines averaged 1.60 and 1.59 bird species per Observation Point, respectively. Array Areas averaged 1.28 bird species per Observation Point, Baseline averaged 1.45 species and grassland Reference Sites averaged 1.24 species.

Preliminary data suggest a reduction in species richness between the Baseline category and the completed Array Area category.

TABLE 4. PRELIMINARY SPECIES RICHNESS COMPARISON.

Survey Area Category	Ave No. Species per Obs. Point	Total Number of Species
Baseline	**1.45**	**33**
Reference Site	**1.24**	**20**
Overhead Powerline	**1.59**	**18**
Energized Equipment	**1.60**	**14**
Array Area	**1.28**	**18**

FIGURE 2. AVERAGE SPECIES RICHNESS.



2.2.3 Preliminary species composition

Species composition refers to the relative abundance of different species in a given area. For each species we calculated the average number of birds detected for Observation Points within each of the five survey area categories (Table 5). We looked at the 6 most abundant species detected from November 2011 through December 2012: horned lark, house finch, savanna sparrow, long-billed curlew, common raven and mountain bluebird.

Of the 6 most abundant species detected, the Baseline and Reference Site categories detected all 6 species, or 100%. Both of these categories represent non-developed habitat. Overhead Powerline and Energized Equipment categories detected 5 of the 6 most abundant species (83%). Completed Array Areas detected only 4 of the 6 most abundant species, or 67% (Table 5).

TABLE 5. PRELIMINARY SPECIES COMPOSITION COMPARISON. Average number of individuals is listed for each of the 6 species within the five survey area categories. Percent of top 6 species is listed at far right.

Survey Area Category	Horned Lark Ave #	House Finch Ave #	Savanna Sparrow Ave #	Long-billed Curlew Ave #	Common Raven Ave #	Mountain Bluebird Ave #	% of Top 6 Species Recorded
Baseline	3.11	0.57	0.39	0.35	0.32	0.19	**100%**
Reference Site	2.32	1.04	0.14	0.17	0.18	0.67	**100%**
Overhead Powerline	1.72	0.35	0.34	0.00	0.02	0.01	**83%**
Energized Equipment	1.33	0.60	0.28	0.00	0.02	0.02	**83%**
Array Area	3.80	0.11	0.02	0.00	0.01	0.00	**67%**

2.2.4 2012 Bird Utilization Rate Calculations

Bird Utilization Rate (BUR) is calculated as the number of unique bird observations divided by the number of observation point counts. Each month 63 observation point counts are randomly chosen and surveyed for 10 minutes each. A unique bird observation is recorded each time a bird or group of birds enters the survey area.

We calculated Bird Utilization Rate for five survey area types: Array Areas, Overhead Powerlines, Energized Equipment (Substation), Reference Site (grassland) and Baseline (future work area, cropland or grassland). Where an Array Area, Overhead Powerline, or Energized Equipment survey point was conducted prior to construction commencement at that location, that point was categorized as a Baseline site since no construction activities or project facilities were present.

Average BUR for each survey area type was calculated for 2012 (Figure 3 and Table 6). Reference sites had the highest BUR, at 4.82. Array Areas were second highest, with an average BUR 3.66, and Baseline, Overhead Powerline and Energized Equipment were roughly similar with BUR of 2.97, 2.96 and 2.83 respectively.

Bird Utilization Rates were also calculated and graphed by month, for each of the five survey area types (Figure 4). Note that surveys in November and December 2011 did not include all survey area types since construction had not commenced.

FIGURE 3. 2012 AVERAGE BUR FOR ALL SURVEY AREA TYPES.

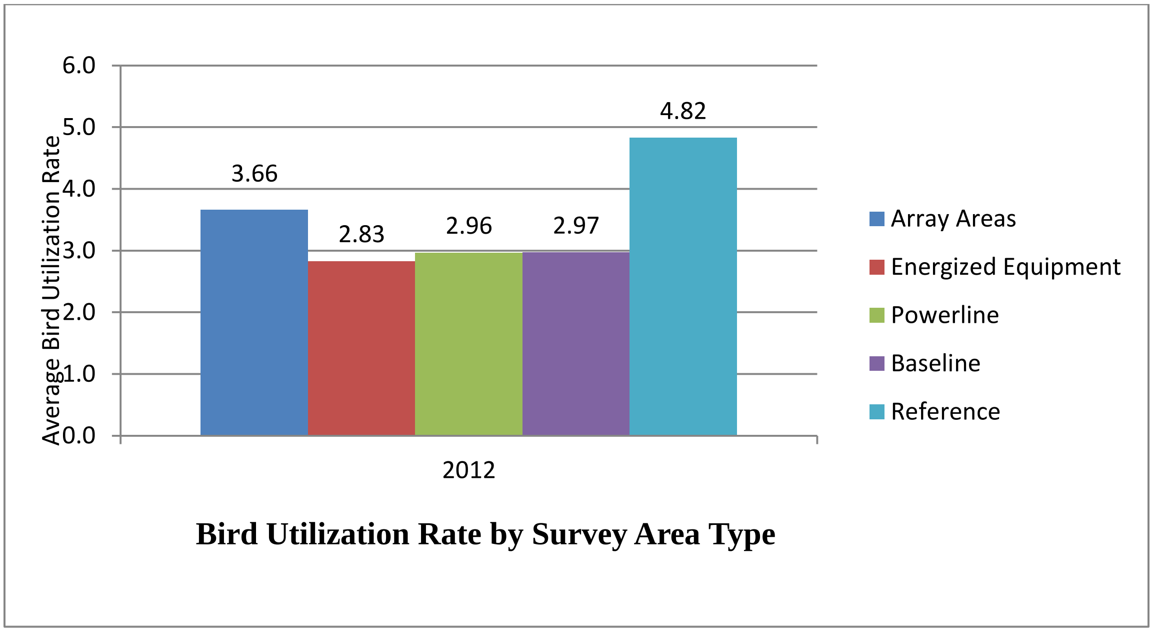


TABLE 6. BIRD UTILIZATION RATE BY SURVEY AREA TYPE. BUR is provided for each of the survey area types by month. Total monthly average BUR is provided in the last column, and average BUR for the year 2012 is provided at the bottom.

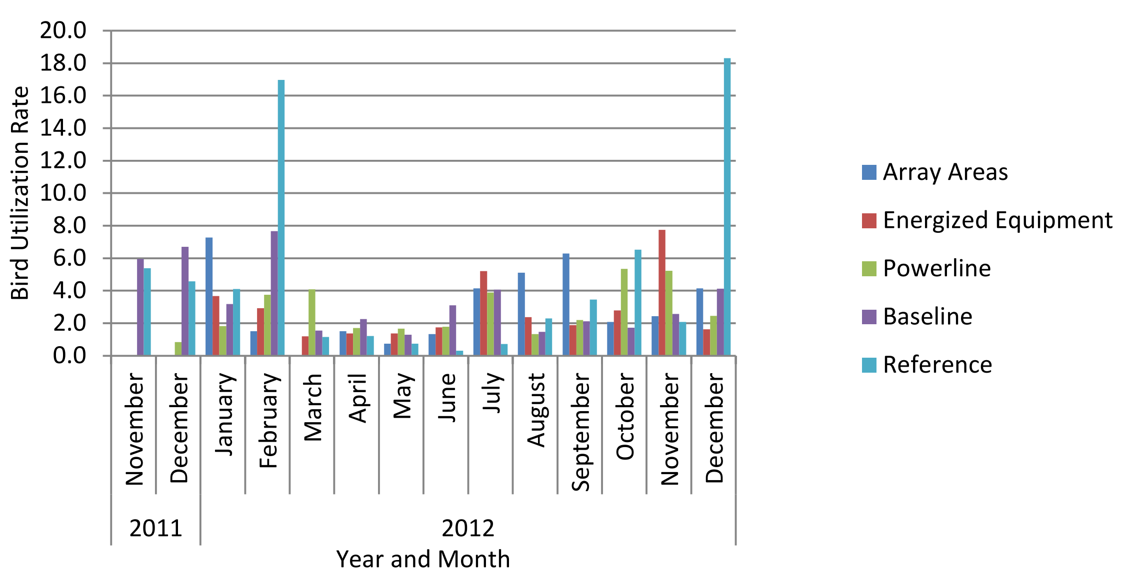
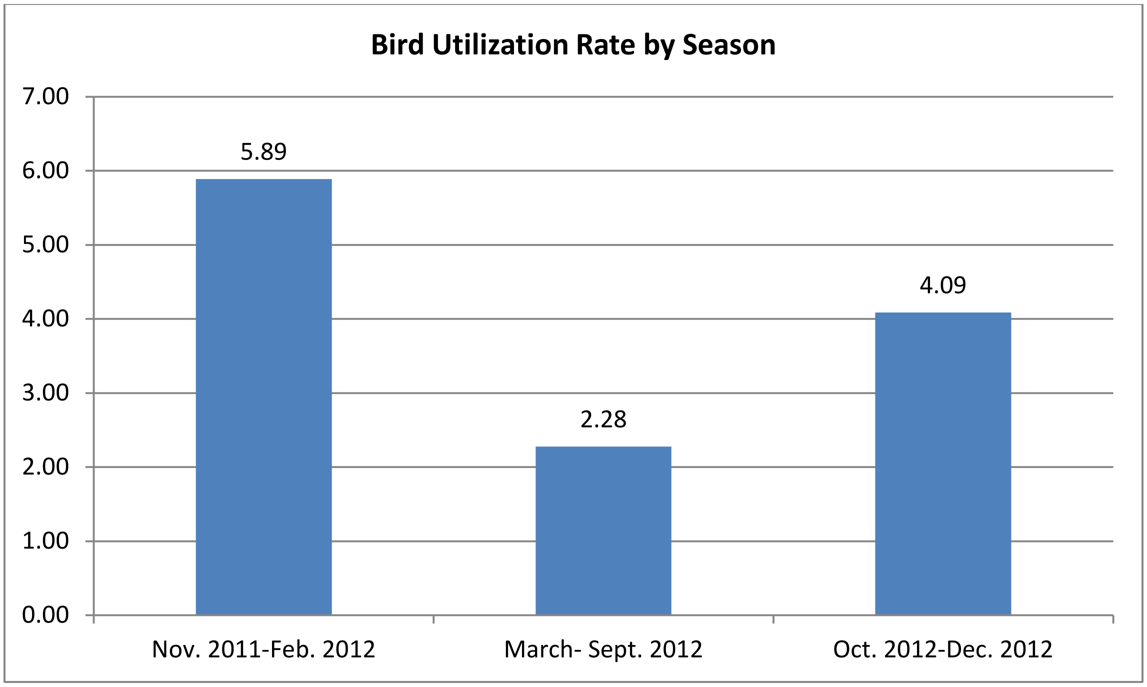
Year/Month	Array Areas	Energized Equipment	Overhead Powerline	Baseline	Reference	Average
2011 November	n/a	5.96	5.38	5.86	n/a	5.96
2011 December	0.83	6.71	4.59	6.09	0.83	6.71
2012 January	7.28	3.68	1.83	3.19	4.11	3.28
2012 February	1.50	2.92	3.75	7.67	16.98	8.31
2012 March	0.00	1.19	4.08	1.55	1.15	1.68
2012 April	1.50	1.38	1.70	2.26	1.21	1.97
2012 May	0.75	1.38	1.67	1.30	0.75	1.25
2012 June	1.33	1.75	1.79	3.11	0.30	2.30
2012 July	4.14	5.21	3.89	4.07	0.72	3.59
2012 August	5.10	2.38	1.33	1.47	2.30	2.22
2012 September	6.29	1.88	2.20	2.11	3.46	2.92
2012 October	2.08	2.79	5.35	1.72	6.53	3.18
2012 November	2.43	7.75	5.22	2.57	2.08	3.17
2012 December	4.15	1.63	2.44	4.12	18.30	5.90
Average of 2012 Monthly Surveys	**3.66**	**2.83**	**2.96**	**2.97**	**4.82**	**3.32**

FIGURE 4. MONTHLY BIRD UTILIZATION RATE. The Bird Utilization Rate is indicated for each of the five survey area types during each month from November 2011 through December 2012.



Bird Utilization Rate indicates highest general bird use during the winter period from October through February, with average BUR from November 2011 to February 2012 of 5.89 and an average BUR of 4.09 from October 2012 to December 2012. By comparison, the non-winter period spanning March to September 2012 had an average BUR of 2.28 (Figure 5). This is generally consistent with the influx of wintering birds which gather in large flocks in the Carrizo Plain during this time. Based on these preliminary results we would expect the risk of bird mortality to be higher during the winter period, if all other variables remain the same, simply due to the higher number of birds present.

FIGURE 5. BIRD UTILIZATION RATE BY SEASON. Average BUR is graphed for winter and non-winter periods.



2.3 Avian Fatality Surveys

Avian Fatality Surveys commenced upon completion of the first project components. Avian Fatality Surveys are conducted at randomly selected locations within four different survey area types: Array Areas, Overhead Powerlines, Energized Equipment (Substation) and at Reference sites[1]. Each survey area type was divided into 500 foot by 15 foot search plots. Search plots are randomly selected using an ArcGIS random point generator having defined areas as the constraining polygon. Avian Fatality Surveys are conducted within the same search plots each day for seven consecutive days every month. Repetitive surveys increase the chance of finding fatalities in a given area before predators remove the carcass. Exhibit 2 depicts the search plots covered by Avian Fatality Surveys in 2012.

During the period of July 1 through September 31, 2012 we conducted test fatality surveys at various locations during construction phases; however, no formal surveys were conducted due to incomplete project components. We used these preliminary results to guide our survey efforts in the Array Areas starting in October 2012.

In October 2012 we completed walking Avian Fatality Surveys at 168 five hundred foot transects within completed Array Area search plots, for 7 consecutive days each, totaling 1,176 search plots (111.4 linear miles, 207.3 acres) for the month. No avian fatalities

---

[1] Select Array Areas were completed and safe to conduct surveys by October 2012. The first Overhead Powerline areas were completed by the December survey. Energized Equipment areas were not complete with construction in 2012 and were therefore not surveyed.

were detected during the October survey (Table 7). Since Overhead Powerline and Substation construction were not complete, no search plots in these survey area types were conducted. We consider the October 2012 Array Area data to be a test to determine labor hours required per search plot, therefore no Reference Site search plots were conducted for comparison. This data is not included in the 4th quarter Average Fatality Rate calculation provided in Table 7, last row.

In November 2012 we completed walking avian fatality surveys at 84 five hundred foot transects within completed Array Area search plots, for 7 consecutive days each, totaling 588 search plots (55.7 linear miles, 103.7 acres). A total of 84 Grassland Reference Site search plots were completed, for 7 consecutive days each, totaling 55.7 linear miles (101.8 acres). One bird fatality was detected in the Array Area search plots and four fatalities were detected in the Reference Site search plots. The Array Area fatality was a very old mourning dove feather pile in which the cause of death could not be determined. The fatalities recorded in the Reference Site search plots consisted of two American kestrels, one domestic chicken, and one unidentified species. Each of these fatalities consisted of feather piles, and in one case (the unidentified species), a bone fragment. Cause of death could not be determined for any of the fatalities, however predation was presumed to be the likely cause for each.

In December 2012 we completed walking Avian Fatality Surveys at 126 five hundred foot transects within completed Array Area search plots, for 7 consecutive days each, totaling 882 search plots (83.5 linear miles, 155.5 acres). Powerline search plots included 3 five hundred foot transects, surveyed for 7 consecutive days each, totaling 2.0 linear miles (3.6 acres). A total of 12 grassland Reference Site search plots were completed, for 7 consecutive days each, totaling 84 linear miles (152.7 acres). One fatality was recorded in the Array Area search plots. The fatality was a domestic chicken in which only feathers were found. The cause of death was determined to be predation. No fatalities were recorded in the Powerline or Reference Site search plots.

2.3.1 2012 Bird Fatality Rate Calculations

Bird Fatality Rate (BFR) is calculated for three of the four survey area types as the number of unique bird carcasses detected divided by the number of plots searched (Table 7). Energized Equipment (Substation) was not completed in 2012 and was therefore not surveyed. The highest 4th Quarter (November and December 2012) BFR was recorded for the Reference Site search plots (0.003). The Array Area search plots had a BFR of 0.001. No bird fatalities were recorded in the Overhead Powerline search plots, so the BFR is zero.

TABLE 7. BIRD FATALITY RATE DATA.

2012 Data	**Array Areas**	**Energized Equipment**	**Overhead Powerline**	**Reference (Grassland)**
Number of Search Plots				
October Search Plots	**1,176**	**0**	**0**	**0**
November Search Plots	**588**	**0**	**0**	**591**
December Search Plots	**882**	**0**	**21**	**887**

2012 Data	Array Areas	Energized Equipment	Overhead Powerline	Reference (Grassland)
Number of Bird Fatalities				
October Bird Fatalities	**0**	--	--	--
November Bird Fatalities	**1**	--	--	**4**
December Bird Fatalities	**1**	--	**0**	**0**
Bird Fatality Rate (No. Fatalities/No. Search Plots)				
October Bird Fatality Rate	**0**	--	--	--
November Bird Fatality Rate	**0.002**	--	--	**0.007**
December Bird Fatality Rate	**0.001**	--	**0**	**0**
4th Quarter Average Fatality Rate (Nov. & Dec data)	**0.001**	--	**0**	**0.003**

2.4 Scavenger Trials and Searcher Efficiency Trials

Scavenger trials and searcher efficiency trials are proposed to determine any bias in the fatality survey results. These trials will not commence until construction is complete in designated project component areas[2].

2.5 Preliminary Bird Risk Index Calculations

Bird Risk Index (BRI) is calculated in order to quantify multiple measures into a single number to facilitate comparison of the different survey area types and to monitor for trends over time. For this BMAP study, BRI is calculated as the Bird Fatality Rate divided by the Bird Use Rate (Table 8). We are providing a preliminary BRI for each survey area type in this first annual report, but acknowledge that insufficient fatality surveys were completed in 2012 to provide a strong conclusion. Significance thresholds should not be based on these preliminary results.

The offsite grassland Reference Site search plots had a Bird Risk Index double that of the Array Area search plots. Bird fatality detections were extremely low in both the Array Area and Reference Site search plots. No bird fatalities were detected in the Overhead Powerline search plots, however we surveyed significantly fewer search plots within this survey area type compared with Array Areas and Reference Sites.

---

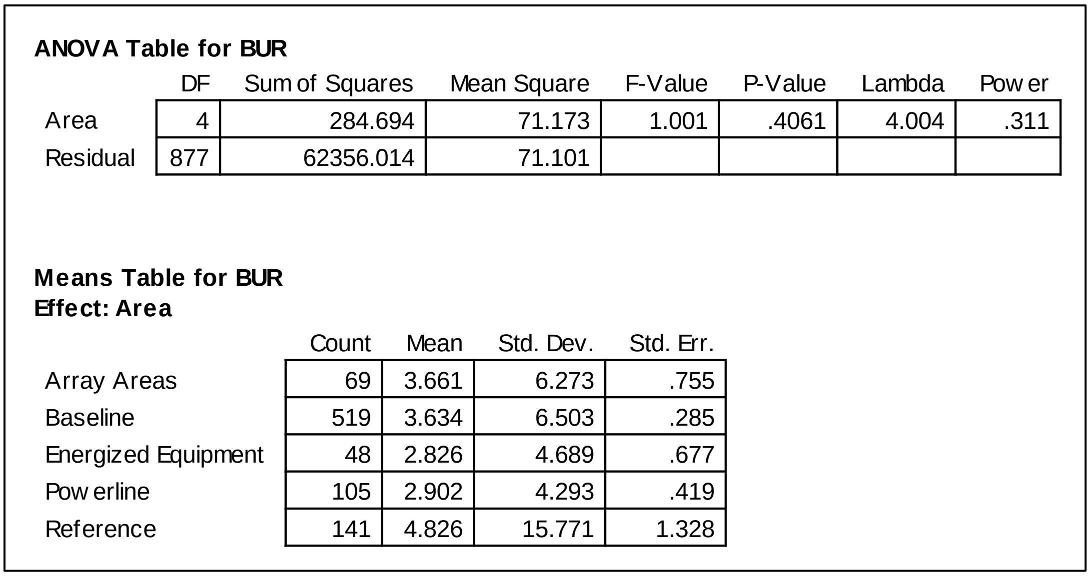
[2] Scavenger trials and searcher efficiency trials commenced in February 2013.

TABLE 8. PRELIMINARY BIRD RISK INDEX. BUR, BFR and BRI are provided for the Array Area, Overhead Powerline, Energized Equipment and Reference Site search plots.

Survey Area Type	Bird Utilization Rate (BUR)	Bird Fatality Rate (BFR)	Bird Risk Index (BRI)
Array Area	3.66	0.001	0.0003
Overhead Powerline	2.96	0	0
Energized Equipment	2.83	n/a	n/a
Reference Site	4.82	0.003	0.0006

Statistical analysis of the BUR found no difference among treatment types (areas) across the study area. This is due to the large variation in the bird observation point data results (Table 9).

TABLE 9. BUR STATISTICAL ANALYSIS.



ANOVA Table for BUR

	DF	Sum of Squares	Mean Square	F-Value	P-Value	Lambda	Power
Area	4	284.694	71.173	1.001	.4061	4.004	.311
Residual	877	62356.014	71.101				

Means Table for BUR
Effect: Area

	Count	Mean	Std. Dev.	Std. Err.

Powerline	105	2.902	4.293	.419
Reference	141	4.826	15.771	1.328

3.0 Discussion

Avian Use Surveys were conducted for all 12 months of 2012. A total of 63 observation points were surveyed each month, for a total of 756 for the year. For observation points in Array Areas where panels were installed, observer visibility was limited. This effect could potentially reduce the number of unique bird detections per observation point compared with open Reference Site observation points. Although we anticipated this effect, we are concerned that the severity of the sight limitation may be worse than anticipated. Therefore we decided to change the parameters of our random selection criteria for 2013 so that observation points for the Array Areas only fall on interior north-south oriented access roads. This selection criterion will only choose observation points that allow visibility to the 50 meter survey area extent to the north and south along the narrow access road, as well as to the east and west down the panel rows, while still collecting data on bird use within the Array Areas.

A total of 250.6 linear miles of 15-foot wide Avian Fatality Survey search plots were systematically surveyed on foot by project biologists within completed Array Areas; two bird fatalities were recorded. One fatality was a domestic chicken that was obviously brought to the location by a predator. The other fatality was an old mourning dove feather pile that suggested raptor predation; however cause of death was recorded as unknown. Grassland Reference Site search plots covered a total of 139.7 linear miles of 15-foot wide search plots. Four fatalities were recorded in the Reference Site search plots. Cause of death could not be determined for any of these fatalities, however predation was presumed to be the likely cause for all. General fatality rates appear to be very low in work areas (1 fatality every 125 miles of array rows).

Searcher efficiency trials and scavenger/carcass removal trials will be conducted in 2013 to provide insight into the accuracy of Avian Fatality Survey data. Results of these trials will be reported in the first quarterly report for 2013, and the second annual report will include Fatality Survey data adjusted to account for the results of the trials.

Quarterly Report

COA 62 Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan Quarterly Report

April 10, 2014

Discussion

This report has been prepared to address the reporting requirements for Condition of Approval (COA) 62 Bird Monitoring and Avoidance Plan. The BMAP report was prepared to include bats and the title revised to the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP).

In response to COA 62, the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP) has been prepared, which further describes the approach to implementing the condition requirements.

COA 62 requires quarterly and annual reports. Quarterly reports are required during construction and for three years following the beginning of the solar farm operation.

Following the completion of the fourth quarter of monitoring the biologist shall prepare an annual report that summarizes the year's data, analyzes any project-related bird fatalities or injuries detected, and provides recommendations (in consultation with the County) for future monitoring and any adaptive management actions needed.

Quarterly Reportable Items

COA 62 BMAP requires quarterly reports describing the dates, durations, and results of monitoring and data collection. The quarterly reports shall provide a detailed description of any project-related bird or wildlife deaths or injuries detected during the monitoring study or at any other time.

Report Data

Attached is the quarterly report prepared by Althouse & Meade (COA 62 and ABPP Quarterly Monitoring Report by Althouse & Meade January 1 – March 31, 2014).

1.0 Introduction

This Year 3 First Quarter report provides information pertinent to the reporting obligations regarding implementation of various tasks required by the Topaz Solar Farms Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (Althouse and Meade, Inc. June 2011). Section 5.5 of this plan requires quarterly reports to be submitted to the County of San Luis Obispo, U.S. Fish and Wildlife Service (USFW) and the California Department of Fish and Wildlife (CDFW). The Avian and Bat Protection Plan (ABPP) and Bird Monitoring and Avoidance Plan (BMAP) are requirements of County of San Luis Obispo Conditions of Approval (COA) 61 and 62, and were prepared in consultation with USFWS and CDFW.

2.0 Avian and Bat Protection Plan

The ABPP monitoring program compiles general information on bird and bat interactions, injuries, and mortality at the Topaz Solar Farms. During construction phases of the project this task is completed by the project biologists, as part of routine daily biological monitoring. Information regarding a detailed bird use and mortality risk assessment study is reported below under the BMAP section.

This quarterly report provides information spanning the period from January 1 through March 31, 2014. Construction of Blocks 1 through 10 was completed in 2013. Blocks 14 and 15 were completed during the current reporting quarter (January - March 2014). Blocks 1 through 10, 14, and 15 are now managed through Operations and Maintenance (O&M) and Blocks 11, 12, and 13 are managed by Commissioning. Blocks 16 through 22 are active construction areas as of March 31, 2014. Figure 1 illustrates construction status of blocks through March 2014.

2.1 General Bird Surveys

2.1.1 Methods

General bird surveys are conducted on and around the TSF project site on a daily basis seven days a week throughout the year by project biologists. Lists of bird species observed by each biological monitor are recorded on daily construction survey forms, which are then scanned, archived, and reviewed by project ornithologists Peter Gaede and Jason Dart.

2.1.2 Results

Monitors recorded a total of 69 species of birds in January, February, and March 2014 and an additional three species that could only be identified to genus. Of those 69 species, 15 were waterbirds and 12 were raptors. Most waterbirds were observed at or near the dust control pond (DCP); some were seen flying over the project site without using project features as habitat. Table 1 lists all bird species observed in this quarter with information on observation frequency.

Table 1. January – March 2014 General bird Survey Observations. All species observed this quarter are listed below. Bolded species were the top twenty species most frequently observed; blue type represents a waterbird.

American Coot
American Crow
American Goldfinch
American Kestrel
American Pipet
Anna's Hummingbird
Bald Eagle
Barn Swallow
Black Phoebe
Brewer's Blackbird
Bullock's Oriole
Burrowing Owl
California Thrasher
California Towhee
Canada Goose
Cassin's Kingbird
Cinnamon Teal
Cliff Swallow
Common Raven
Cooper's Hawk
Dark-Eyed Junco
Eurasian Collared Dove
European Starling
Ferruginous Hawk
Golden Eagle
Greater Roadrunner
Greater Yellowlegs
Horned Lark
House Finch
House Sparrow
Killdeer
Lapland Longspur
Lark Sparrow
Lawrence's Goldfinch
Lesser Goldfinch
Loggerhead Shrike
Long-Billed Curlew
Long-Billed Dowitcher
Mallard
McCown's Longspur
Merlin
Mountain Bluebird
Mourning Dove
Northern Flicker
Northern Harrier
Northern Mockingbird
Northern Pintail
Northern Shoveler
Orange-Crowned Warbler
Osprey
Prairie Falcon
Red-Tailed Hawk
Red-Winged Blackbird
Rock Pigeon
Ruby-Crowned Kinglet
Ruddy Duck
Savannah Sparrow
Say's Phoebe
Sharp Shinned Hawk
Snowy Egret
Tree Swallow
Tri-Colored Blackbird
Turkey Vulture
Violet-Green Swallow
Western Kingbird
Western Meadowlark
Whimbrel
White-Crowned Sparrow
Yellow-Rumped Warbler
Hummingbird sp.
Swallow sp.
Yellowlegs sp.

2.2 Nesting Activity

2.2.1 Methods

Focused nest surveys were conducted daily on and around the project site by biological monitors starting February 1, 2014. All nest surveys were conducted on foot by trained biologists. Strategically selected array areas were identified at the beginning of each week where surveyors walked all rows searching for nests on the ground or structures. Additionally, areas up to 300 feet outside the perimeter fences were surveyed twice per week. Laydowns were surveyed as often as possible to prevent birds establishing nests in equipment and materials. Nest starts were removed when the presence of a complete nest would conflict with construction activities or would present a danger to the birds. All nests and nest starts identified from January to March 2014 were documented.

2.2.2 Results

The results of surveys from January through March 2014 are provided in Table 2. Other species identified nesting offsite (e.g. mitigation lands, future project lands, or areas managed by Operations and Maintenance) are not included in this table. Additionally, as of March 31, there are at least two burrows occupied by burrowing owl pairs outside project perimeter fences. At this time, no chicks have been documented outside the burrows. Fourteen horned lark nest starts have been removed from or near project areas during this quarter as well as three house finch nest starts from material stacks and a common raven nest start from a crane boom. All nest starts were removed prior to being deemed complete, which is defined as a nest that is lined and ready to accept eggs. Common ravens and red-tailed hawks are currently building nests on the PG&E transmission lines, power poles, and the TSF's medium voltage collector line poles. At the end of March, a female red-tailed hawk was seen sitting in a nest north of Block 11 on a PG&E transmission tower and will be monitored in April to determine whether or not the nest is considered active. A map of active nests for January to March 2014 is attached (Figure 2).

TABLE 2. JANUARY – MARCH 2014 BIRD NESTS. Bird nests detected at the Topaz Solar Farms from January to March 2014.

Month	Species	Date Found	Location	Current Status
Jan.	-	-	-	-
Feb.	-	-	-	-
Mar.	Horned Lark	13-Mar-14	North of Block 17	Potentially depredated
		25-Mar-14	Block 18	Inactive with cold eggs in nest
		26-Mar-14	West of Block 22	Active with female incubating eggs
		28-Mar-14	North of Block 17	Nest being built
		31-Mar-14	North of Block 20	Active with eggs and female attending

2.3 Avian and Other Wildlife Mortality

General biological monitoring of the Topaz work areas documented bird, bat, and other wildlife mortality. All mortality identified on site during this reporting period is provided in Table 3. Cause of death is reported when known. This table includes all fatalities found in active construction areas as well as areas managed by Commissioning or Operations and Maintenance.

TABLE 3. JANUARY – MARCH 2014 AVIAN AND OTHER WILDLIFE MORTALITY. Bird and other wildlife mortality detected at the Topaz Solar Farms from January to March 2014.

Month	**Species**	**Location**	**Cause of Death**	**Notes**
Jan.	American Kestrel	Block 19	Predation	Seen eaten by Cooper's hawk
	Burrowing Owl	Block 7	Unknown	Feathers only
	Common Raven	Block 14 Laydown	Unknown	Wing and feathers
	Common Raven	Block 9	Predation	Feathers only
	Common Raven	Block 7	Unknown	Feathers only
	Horned Lark	Block 18	Predation	Seen eaten by kestrel
	Horned Lark	Block 9	Unknown	Feathers only
	Mourning Dove	Block 9	Unknown	Feathers only
	Mourning Dove	Block 8	Unknown	Feathers only
	Mourning Dove	Block 6a	Predation	Feathers only
	Cottontail Rabbit	Block 16	Unknown	
	Cottontail Rabbit	Helios Way	Vehicle Strike	
	Gopher Snake	Block 21 Laydown	Equipment Strike	
	Ground Squirrel (6)	Dust Control Pond	Drowning	
Feb.	Horned Lark	Block 17	Unknown	Feathers only
	Horned Lark	Block 19	Presumed Collision	Potentially collided with post
	Mourning Dove	Block 3	Unknown	Feathers only
	Western Meadowlark	Block 2	Predation	Feathers only
	Gopher Snake	Phase 6 Road	Vehicle Strike	
	Ground Squirrel	Block 13	Unknown	
	Ground Squirrel	Block 18	Vehicle Strike	
	Jack Rabbit	Papich Laydown	Predation	
	Pocket Mouse	Block 16	Exposure	
Mar.	Barn Owl	Block 1	Predation	Head, spine, and wings
	Common Raven	Block 14	Unknown	Feathers and flesh
	Common Raven	Block 13	Unknown	Full carcass
	Horned Lark	Block 18	Collision	Potentially collided with post
	Horned Lark	Block 20	Collision	Potentially collided with post
	Cottontail Rabbit	Block 16	Unknown	

2.4 Adaptive Management

No adaptive management practices were implemented during the period from January to March 2014.

2.5 Bat Surveys

Acoustic monitoring surveys for bats on the project site were conducted at least one night per month using a Pettersson D240x (Pettersson Elektronik, Sweden) bat detector and Sonobat® (v.3.1 US west; DNDesign, Arcata, CA) acoustic analysis software. On January 24, 2014 the detector was placed on the south fence of the Dust Control Pond (DCP) and in February and March, the detector was placed on an extendable pole on a t-post between the Topaz Solar Farms substation and the PG&E switching station. All detected bat calls were identified using the analysis software.

Only one species of bat was detected from January through March, Mexican free-tailed bat (*Tadarida brasiliensis*). Mexican free-tailed bats are one of the most widely distributed mammalian species in the Western Hemisphere. They may fly more than 50 km a night to reach foraging areas. The results of the March 19 survey showed no bat detections, however, sound files from the survey suggest the presence of acoustic interference with the detector. Table 4 provides a list of the number of detections of each bat species detected from January through March 2014. Each detection was assigned to species with a discrimination probability of 0.95 or higher.

TABLE 4. TOPAZ SOLAR FARMS JANUARY TO MARCH 2014 BAT SURVEYS. Bat acoustic monitoring survey dates, bat species detected at the Topaz Solar Farms project, and number of detections. Special status designations from CDFW and Western Bat Working Group (WBWG) are provided.

Survey Date	Location	Total Detections	Common Name	Scientific Name	CDFW Status	WBWG Status
24-Jan-14	DCP	1	Mexican [=Brazilian] free-tailed bat	*Tadarida brasiliensis*	None	Low
14-Feb-14	Substation	10	Mexican [=Brazilian] free-tailed bat	*Tadarida brasiliensis*	None	Low
19-Mar-14	Substation	0	--	--	--	--
28-Mar-14	Substation	3	Mexican [=Brazilian] free-tailed bat	*Tadarida brasiliensis*	None	Low

No bat roosts are known to be present within or near the Topaz project site.

3.0 Bird Monitoring and Avoidance Plan

The BMAP study analyzes avian use surveys and avian fatality surveys to produce a risk index for various project components deemed to be potentially dangerous to birds, including array areas, overhead power lines and the Substation.

3.1 Avian Use Surveys

3.1.1 Methods

Avian Use Surveys were conducted monthly from November 2011 through March 2014, and will continue throughout the construction period and for three years after construction is complete. Each month, 63 randomly selected survey points are completed, including 31 inside existing array areas, 18 along existing overhead power lines, 10 in grassland reference sites and 4 at the energized equipment (substation). At each point, a 10 minute bird use count is conducted within a 50 meter radius of the surveyor. Avian Use Survey points were randomly selected each month across all six phases of the project and in offsite grassland reference areas (Figure 3).

3.1.2 Results

The four Survey Area Categories used as treatment types in this study comprise different habitat elements that influence species composition, abundance, and richness.

The Array Area category includes point counts conducted within solar array areas during active construction and in completed form. The habitat consists of rows of passive (non-moving) photovoltaic solar panels mounted to steel racking ranging from approximately 2 to 5 feet off the ground. The ground is seeded with a native seed mix to revegetate array areas to naturalized grassland habitat; vegetation density varied from 0 to 60 percent cover. Array Area survey points may also include perimeter fences, photovoltaic combining switchgear houses, as well as array roads.

The Energized Equipment category includes point counts conducted around the perimeter of the substation. The survey area includes the substation perimeter fence, transformers, power lines, and other electrical components. Within the substation fence the ground is gravel with no vegetation. Outside the perimeter fence, the ground is bare dirt with some patches of grass.

Overhead Powerline surveys represent areas underneath medium-voltage collector lines within the project. Vegetation varies depending on location; most powerlines are along array or access roads, however some locations are outside the fenced project areas in annual grassland habitat.

Reference Sites are composed of annual grassland habitat. They included point counts conducted on mitigation lands owned by California Department of Fish and Wildlife or annual grasslands not yet developed by TSF.

In January, February, and March 2014, 183[1] point counts were conducted in the four survey area categories totaling 356.12 acres. During these surveys, 18 different species were observed (Table 5). The 10 most abundantly detected species, listed in decreasing order of abundance, were: horned lark (916 detections), brewer's blackbird (125), mourning dove (88), common raven (66), house finch (52), European starling (49), western meadowlark (32), tree swallow (29), rock

---

[1] 6 survey points were missed from the proposed total of 189 points (63 points x 3 months).

pigeon (20), and savannah sparrow (7). The most frequently encountered species, the horned lark, was detected more than seven times as often as that of that of the second most frequently encountered species, the brewer's blackbird. Horned larks are abundant year-around residents that commonly form large flocks in winter on the Carrizo Plain. Both the horned lark and brewer's blackbird were detected in high numbers in all project component categories and up to 51 percent less frequently in the grassland reference category.

TABLE 5. SPECIES COMPOSITION AND ABUNDANCE. All bird species detected during Avian Use Surveys in January – March 2014, with the average number of bird use detections per observation point calculated for each of the four survey area categories. Total detections for each species are provided in far right column. Species are listed in decreasing order of abundance according to the total detections column.

Species	**Array Area** Ave. Detections per Obs. Pt.	**Energized Equipment** Ave. Detections per Obs. Pt.	**Overhead Powerline** Ave. Detections per Obs. Pt.	**Grassland/ Reference** Ave. Detections per Obs. Pt.	**Total Detections**
Horned Lark	5.13	5.58	5.92	3.00	916
Brewer's Blackbird	0.40	0.00	1.62	0.15	125
Mourning Dove	0.49	0.00	0.83	0.06	88
Common Raven	0.46	0.00	0.30	0.33	66
House Finch	0.51	0.17	0.13	0.00	52
European Starling	0.02	0.17	0.85	0.00	49
Western Meadowlark	0.20	0.67	0.09	0.09	32
Tree Swallow	0.09	0.00	0.40	0.00	29
Rock Pigeon	0.01	0.00	0.32	0.06	20
Savannah Sparrow	0.04	0.00	0.08	0.00	7
Say's Phoebe	0.02	0.08	0.00	0.03	4
Tri-Colored Blackbird	0.00	0.00	0.06	0.00	3
Red-Tailed Hawk	0.00	0.00	0.06	0.00	3
American Crow	0.02	0.00	0.00	0.00	2
Cliff Swallow	0.00	0.00	0.02	0.00	1
American Kestrel	0.01	0.00	0.00	0.00	1
Ferruginous Hawk	0.00	0.00	0.02	0.00	1
Golden Eagle	0.01	0.00	0.00	0.00	1

Among the treatment types, Overhead Powerline had the highest species richness with an overall average of 1.40 species detected per Observation Point. Array Area and Energized Equipment categories were similar, with 1.20 and 1.17 species detected per Observation Point. Grassland Reference Site recorded an average of 0.97 species per Observation Point. Species richness is higher in all three project component categories than in the offsite undeveloped category.

Bird Utilization Rate (BUR) is calculated as the average number of birds observed per Observation Point count. We calculated Bird Utilization Rate for the four Survey Area Categories for January – March 2014 (Table 6). Overhead Powerline had the highest BUR at 10.70 birds per Observation Point. With 7.41 and 6.75 birds per Observation Point, Array Area and Energized Equipment categories had the second and third highest BUR, and Grassland had the lowest BUR at 3.79 birds per Observation Point.

TABLE 6. AVIAN USE SURVEY POINT COUNTS AND DETECTIONS. The number of point counts conducted and total area surveyed in January – March 2014 is listed for each of the four Survey Area Categories. Species richness and bird utilization rate (BUR) is also listed.

Type	Number of Obs. Pt. Counts	Total Area Surveyed (Acres)	Total No. Species	Average No. Species per Obs. Pt (Species Richness)	Average No. Birds per Obs. Pt (BUR)
Array Area	85	165.41	14	1.20	7.41
Overhead Powerline	53	103.14	14	1.40	10.70
Grassland/Reference	33	64.22	7	0.97	3.79
Energized Equipment	12	23.35	5	1.17	6.75
Total	**183**	**356.12**	**18**	**1.17**	**7.67**

3.2 Avian Fatality Surveys

3.2.1 Methods

Avian Fatality Surveys commenced upon completion of the first project components. Avian Fatality Surveys are conducted at randomly selected locations within four different survey area types: Array areas, overhead power lines, energized equipment (Substation) and at reference sites. Transects walked in each category were 14 feet wide. Survey areas are randomly selected using an ArcGIS random point generator having defined areas as the constraining polygon. Avian Fatality Surveys are conducted within the same search plots each day for seven consecutive days every month. Repetitive surveys increase the chance of finding fatalities in a given area before predators remove the carcass, and allow calculation of number of fatalities per day.

3.2.2 Results

Each month, January through March, we completed walking Avian Fatality Surveys Areas for 7 consecutive days each. Powerline survey areas were completed for 7 consecutive days each, totaling 3.8 linear miles (6.5 acres). Grassland reference site survey areas were completed, for 7 consecutive days each, totaling 72.5 linear miles (123.1 acres). Array search areas were completed for 7 consecutive days each, totaling (123.1 acres). Onsite energized equipment was also surveyed in its entirety for 7 consecutive days, totaling 31.3 acres. See Figure 4 (attached) for a map of Avian Fatality Survey areas for January to March 2014.

Three months of surveys yielded a total distance of 513.8 linear miles and coverage of 872.1 acres. These surveys resulted in discovery of eleven fatalities, five each in grassland and arrays, and one underneath powerlines. See Table 7 for a fatality rate in each of the four categories for a comparison of fatalities found to area surveyed.

TABLE 7. BIRD FATALITY DENSITY. The survey results and efforts are indicated for each of the four survey area categories for the first quarter of 2014.

Plot Type	Linear Miles	Acres	Total Fatalities	Acres/Fatality	Fatality/Acre
Array	217.6	369.3	5	73.9	0.014
Powerline	23.2	39.4	1	39.4	0.025
Grassland/Reference	217.6	369.3	5	73.9	0.014
Energized Equipment	55.4	94.1	0	-	0.000
Total	**513.8**	**872.1**	**11**	**1.7**	**0.053**

Cause of death was recorded for all fatalities, when known. The eleven fatalities documented during Avian Fatality Surveys were the result of two causes: predation and unknown. No confirmed collisions or electrocutions were recorded in any of the Survey Area Categories during survey efforts. Since it is difficult to determine cause of death with certainty, recent guidance from the U.S. Fish and Wildlife Service suggests attributing cause of death to a specific factor and including a confidence percent to indicate how confident the determination was (Table 8; A. Beck and T. Dietsch 2013). Predation as a cause of death is likely much higher than reported, as often times a feather pile could not be confidently linked to a predation event as opposed to a scavenging event.

TABLE 8. CAUSE OF DEATH FOR AVIAN FATALITY SURVEY RESULTS. Cause of death tallied for avian fatalities detected within each of the four survey area categories, January – March, during formal avian fatality surveys. Percentages indicate confidence level.

Plot Type	Unknown	Predation Valid (>90%)	Predation Probable (>50%)	Predation Possible (1-50%)
Array	3	0	1	1
Powerline	1	0	0	0
Grassland/Reference	3	1	1	0
Energized Equipment	0	0	0	0
Total	**7**	**1**	**2**	**1**

Using fatality data collected in the first quarter of 2014 during formal avian fatality surveys, we calculated number of fatalities per acre per day for each of the four Survey Area Categories and extrapolated that to estimated number of fatalities per site per year, where site equals the total area of those components when the project is completed. Our fatality survey method consists of seven consecutive days of surveying the same transects. Since the first day could potentially contain carcasses present for several days, if not months, we excluded those fatalities detected on the first day and based the number of fatalities per acre per day calculation on carcasses found and areas surveyed each of the remaining six days. These data are provided as a bird fatality rate (Table 9). For this analysis, predation fatalities with a confidence level of less than fifty percent were moved to the unknown category for cause of death.

TABLE 9. BIRD FATALITY RATE. Bird fatality rate is indicated for each of the four survey area categories, cumulatively for January, February, and March 2014. Values shown exclude the first days' data. Calculations are shown for number of fatalities per acre per year, fatalities per site per year, and fatalities per site per year based on Reference Site fatality rate.

Plot Type	**Days Surveyed**	**Survey Area (Acres)**	**Cause of Death**	**Total Fatalities**	**Fatalities/Ac**	**Fatalities/Ac/ Yr**	**Fatalities/Site/ Yr**	**Fatalities/Site/ Yr (Reference Rate)**

Quarterly Report

COA 62 Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan Quarterly Report

October 14, 2013

Discussion

This report has been prepared to address the reporting requirements for Condition of Approval (COA) 62 Bird Monitoring and Avoidance Plan. The BMAP report was prepared to include bats and the title revised to the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP).

In response to COA 62, the Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (ABPP) has been prepared, which further describes the approach to implementing the condition requirements.

COA 62 requires quarterly and annual reports. Quarterly reports are required during construction and for three years following the beginning of the solar farm operation.

Following the completion of the fourth quarter of monitoring the biologist shall prepare an annual report that summarizes the year's data, analyzes any project-related bird fatalities or injuries detected, and provides recommendations (in consultation with the County) for future monitoring and any adaptive management actions needed.

Quarterly Reportable Items

COA 62 BMAP requires quarterly reports describing the dates, durations, and results of monitoring and data collection. The quarterly reports shall provide a detailed description of any project-related bird or wildlife deaths or injuries detected during the monitoring study or at any other time.

Report Data

Attached is the quarterly report prepared by Althouse & Meade (COA 62 and ABPP Quarterly Monitoring Report by Althouse & Meade October 15, 2013).

Avian and Bat Protection Plan

and

Bird Monitoring and Avoidance Plan

Quarterly Report for July 1 – September 30, 2013

This third quarterly report provides information pertinent to the reporting obligations regarding implementation of various tasks required by the Topaz Solar Farms Avian and Bat Protection Plan and Bird Monitoring and Avoidance Plan (Althouse and Meade, Inc. June 2011). Section 5.5 of this plan requires quarterly reports to be submitted to the County of San Luis Obispo, U.S. Fish and Wildlife Service (USFW) and the California Department of Fish and Wildlife (CDFW). The Avian and Bat Protection Plan (ABPP) and Bird Monitoring and Avoidance Plan (BMAP) are requirements of County of San Luis Obispo Conditions of Approval (COA) 61 and 62, and were prepared in consultation with USFWS and CDFW.

Avian and Bat Protection Plan

The ABPP monitoring program compiles general information on bird and bat interactions, injuries, and mortality at the Topaz Solar Farms. During construction phases of the project this task is completed by the project biologists, as part of routine daily biological monitoring. Information regarding a detailed bird use and mortality risk assessment study is reported below under the BMAP section.

This quarterly report provides information spanning the period from July 1 through September 30, 2013. Construction of Blocks 1, 2, 3, and 6 (A and B) was completed by the end of the first quarter (March 2013); Blocks 4, 5, 7, and 8 were completed by end of the second quarter (June 2013); and Block 9 was completed during the current reporting quarter (July - September 2013). Blocks 1 through 9 are now managed through Operations and Maintenance (O&M). Blocks 10-15 are active construction areas as of September 30, 2013. Figure 1 illustrates construction status of blocks through September 2013.

Nesting Activity

General bird surveys were conducted on and around the project site by biological monitors. All nests and nest starts identified from July to September 2013 were documented. The results of surveys from July to September 2013 are provided in Table 1. Other species nesting offsite (e.g. mitigation lands or future project lands) are not included in this tally. A map of active nests for July to September is attached (Figure 2).

TABLE 1. BIRD NESTS. Bird nests detected at the Topaz Solar Farms from July through September 2013.

ID	Species	Date Found	Location	Buffer Size	Date Predated	Date Fledged	Date Inactive	Current Status	Notes
AE8	Burrowing Owl	7/1/13	West of Block 15 Stewardship Land	None (Outside Project Site)	n/a	Unknown	8/31/13	Inactive	There were two adults and two nestlings in July, last survey 8/31 no owls present
PG19	House Finch	7/8/13	Block 14 Array 19	75 feet to the north and south, 100 feet to the east and west	n/a	n/a	8/1/13	Inactive	Nest located in electrical coil; nestling found deceased on 8/1
GS46	Mourning Dove	8/30/13	Block 15 Array 15	25 feet	n/a	n/a	9/3/13	Inactive	Eggs determined to be not viable upon inspection following surveys

Avian and Other Wildlife Mortality

General biological monitoring of the Topaz work areas documented bird, bat, and other wildlife mortality. All mortality identified on site from July through September 2013 is provided in Table 2. Cause of death is reported when known.

TABLE 2. AVIAN AND OTHER WILDLIFE MORTALITY. Bird and other wildlife mortality detected at the Topaz Solar Farms from July through September 2013.

Species	Location	Cause of Death	Notes
July 2013			
Pacific Gopher Snake *Pituophis catenifer catenifer*	Block 11	Vehicle Strike	
Common Raven *Corvus corax*	Block 13	Presumed predation	Common raven kill site
California Ground Squirrel *Spermophilus beecheyi*	Dust Control Pond	Drowning	Removed ground squirrel carcass from DCP
California Ground Squirrel *Spermophilus beecheyi*	East perimeter road Block 14 Array 6	Vehicle Strike	Found in middle of road; probable vehicle strike
Common Raven *Corvus corax*	Block 13 Array 12	Unknown	Feather pile; no carcass; cause of death unknown
California Ground Squirrel *Spermophilus beecheyi*	Block 14 Array 19	Predation	Head, front feet, and half of abdomen removed; likely predation
August 2013			
Mourning Dove *Zenaida macroura*	Block 12	Unknown	Wing collected at fatality site
Common Raven *Corvus corax*	Block 13	Potential predation	Numerous common raven feathers
Barn Owl *Tyto alba*	Hotline Route between Blocks 9 and 11	Unknown	Juvenile; rest of carcass found near Arco building
Bat	Block 15 Array 5 in shipping container		Bat found by forklift operator on a panel box after it was removed from a transport container. Container was picked up by driver at the Port of Los Angeles.
Burrowing Owl (*Athene cunicularia*)	Cochrane Pond buffer	Presumed predation	Approximately 30 flight feathers; San Joaquin kit fox scat on feather pile
Domestic Cat *Felis catus*	Secure Laydown		Found crushed under metal conex/storage container in secure laydown. Appears to have been deceased for months as only skeleton, dentition, and fur remained. No soft tissue
September 2013			

Species	Location	Cause of Death	Notes
Unidentified Snake	Block 12 Array 15	Presumed equipment strike	

Adaptive Management

No adaptive management practices were implemented during the period from July 1 through September 30.

Bird Monitoring and Avoidance Plan

The BMAP study utilizes avian use surveys and avian fatality surveys to produce a risk index for various project components deemed to be potentially dangerous to birds, including array areas, overhead power lines and the Substation.

Avian Use Surveys

Avian Use Surveys commenced in November 2011, prior to the start of construction, to gather baseline data on bird use in the project area. Avian Use Surveys will inform the Bird Utilization Rate calculations. Construction commenced in late November 2011 in a limited footprint, and has expanded in area. Avian use surveys were conducted monthly from November 2011 through September 2013, and will continue throughout the construction period and for three years after construction is complete. Each month, 63 randomly selected survey points were completed, for a total of 1,450 survey points completed as of September 2013. The 63 survey points include 31 inside existing or future array areas, 18 along existing or future overhead power lines, 10 in grassland reference sites and 4 at the Substation. At each point, a 10 minute bird use count is conducted within a 50 meter radius of the surveyor.

Avian Use Survey points were randomly selected each month across all six phases of the project and in offsite grassland reference areas (Figure 3). Each month, as construction area increased in size, more of the survey points occurred in developed area. Those points located within future project areas that had not been developed at the time of the survey are categorized as baseline. Baseline condition is similar to reference site condition in that it is not developed, however it differs in being cropland habitat versus grassland habitat.

Avian Fatality Surveys

Avian Fatality Surveys commenced upon completion of the first project components. Avian Fatality Surveys are conducted at randomly selected locations within four different survey area types: Array areas, overhead power lines, energized equipment (Substation) and at reference sites. Each survey area type was divided into 500 foot by 15 foot search plots. Search plots are randomly selected using an ArcGIS random point generator having defined areas as the constraining polygon. Avian Fatality Surveys are conducted within the same search plots each day for seven consecutive days every month. Repetitive surveys increase the chance of finding fatalities in a given area before predators remove the carcass.

Each month, July through September, we completed walking Avian Fatality Surveys at 126 five hundred foot transects within completed Array area search plots, for 7 consecutive days each, totaling 882 search plots (83.5 linear miles, 155.5 acres). Powerline search plots included 3 five hundred foot transects, surveyed for 7 consecutive days each, totaling 2.0 linear miles (3.6 acres). A total of 12 one mile grassland reference site search plots were completed, for 7 consecutive days each, totaling 84 linear miles (152.7 acres). See Figure 4 (attached) for a map of Avian Fatality Survey areas for July to September 2013.

Scavenger/Carcass Removal Trials and Searcher Efficiency Trials

Scavenger Trials and Searcher Efficiency Trials are implemented to identify bias in the Fatality Survey data. For 2013, two Searcher Efficiency Trials will be conducted, one in spring and one in winter. Four Scavenger/Carcass Removal Trials will be conducted in 2103, one each in spring, summer, fall and winter. For the 3rd quarter reporting period, one Scavenger/Carcass Removal trial was conducted; no Searcher Efficiency Trials were conducted.

For both trials we used young commercially-available frozen Coturnix quail. The size and coloration of these birds is similar to meadowlarks and other native birds in the area, and therefore are deemed a suitable surrogate for local native birds. Data collected during the trials will be used to adjust the Year 2 Fatality Survey data that will be compiled in the annual report.

For the Scavenger/Carcass Removal trial, 30 birds were distributed in three treatment areas: 15 thawed quail were randomly placed in completed array area search plots, 15 in grassland reference site search plots, and 2 below overhead power lines.

For the Scavenger/Carcass Removal Trials, we set out the same number and arrangement of birds in each of the three search plot types. Carcasses were checked every day for the first three days after placement, twice a week for the next two weeks, then once per week for the remainder of the 60-day trial, or until all birds were gone.

Birmingham, AL 35203

Dear Ms. Comensky,

Enclosed is your new Special Purpose Utility Permit for Campo Verde Solar, LLC The permit authorizes you and subpermittees to collect, transport and temporarily possess carcasses and partial remains of birds protected under the Migratory Bird Treaty Act (16 U.S.C. 703 et seq.) found on project property and rights-of-way, in accordance with permit conditions. Please read your permit carefully.

Following the permit conditions, bird carcasses may be used for searcher efficiency and scavenger removal trials; carcasses used in trials must be reported to the Service as outlined in Condition E(4) and H(1)(d). You may also transfer carcasses to authorized entities as allowed by the terms of this permit. To comply with your permit reporting requirements, we ask that you submit your data using the "R8 SPUT mortality reporting" spreadsheet we have provided via email.

Feel free to contact me if you have any questions regarding your permit.

Sincerely,

Heather Beeler

Subject: California Valley Solar Ranch Project Avian Bat Protection Plan 2013 Avian Activity Surveys Report

Dear Sirs:

On behalf of High Plains Ranch II LLC, we are submitting the 2013 Avian Activity Surveys Report for the California Valley Solar Ranch (CVSR) Project, San Luis Obispo, California. This report is being submitted per the reporting requirements of the CVSR Avian Bat Protection Plan in compliance with the U.S. Fish and Wildlife Service Biological Opinion (81420-2011-F-0511) and San Luis Obispo County Conditional Use Permit (DRC2008-00097) for the California Valley Solar Ranch, San Luis Obispo California. As required to satisfy, San Luis Obispo County Condition of Approval #58 of the CVSR Project Conditional Use Permit, we are submitting these reports to the County, U.S. Fish and Wildlife Service, and California Department of Fish and Wildlife.

If you should have any questions or comments, please do not hesitate to contact me at (408) 426-7326 or jklingmann@harveyecology.com.

Sincerely,

Julie Klingmann

Executive Summary

Background

The California Valley Solar Ranch Project (CVSR Project) is a 250-megawatt photovoltaic solar power plant recently constructed within an approximately 4685-acre site (Project site), located mostly south of State Route (SR) 58, about 6.4 kilometers (km) east of Soda Lake Road, immediately north of the California Valley subdivision, in the Shandon-Carrizo planning area of San Luis Obispo County (Figure 1). The Conditional Use Permit for the CVSR Project required that an Avian and Bat Protection Plan be prepared and implemented to monitor the impacts of the CVSR Project on birds and bats after construction. In compliance with the resultant Avian and Bat Protection Plan, this Annual Postconstruction Fatality Report documents the number of avian and bat fatalities counted during postconstruction monitoring of the Project between 16 August 2012 and 15 August 2013.

Methods

H. T. Harvey & Associates (HTH) biologists conducted weekly surveys in the following CVSR Project elements: Array 1, Array 2, Array 2 Serengeti, Array 4, Array 5, Array 8, the Medium-voltage Overhead (MVOH) Line, and the Generation-tie (Gen-Tie) Line. During the reporting period, all arrays were surveyed each week at 20% of their total area, with the exception of Arrays 1 and 2, which were surveyed with 100% coverage to inform and strengthen our sampling methods. By collecting data at 100%coverage of these arrays, we were able to determine the spatial pattern of fatalities within the arrays and determine how much of the arrays would need to be surveyed to attain a given confidence level for developing an accurate fatality estimate for increasing our understanding of impacts to avian species from operating solar energy facilities. Further, these arrays were surveyed at 100% for a full year to detect whether or not the distribution of fatalities varied by season. For each of the arrays listed, biologists also surveyed portions of the surrounding fence. Additionally, to help identify the proportion of fatalities found that could be attributed to natural mortality rates, we surveyed control plots, located in Conservation Lands surrounding the CVSR Project site.

In addition to performing weekly surveys, HTH biologists conducted a series of repeat surveys: 5-day repeat surveys, in which biologists searched the same subset of a Project element for 5 consecutive days, and 1-day repeat surveys, in which biologists searched a subset of an area that was searched 1 day previously by either 5-day repeat searchers or weekly searchers. The purpose of these repeat surveys was to check the efficiency of searchers and evaluate the consistency of results; however, as reported herein, not all of the repeat surveys proved necessary.

To estimate the rate of avian and bat fatalities occurring on the site, we used Huso's Fatality Estimator (2010). In formulating a fatality estimate, it was necessary to determine 1) the rate of scavenging that occurs on the site, and 2) how well searchers find different-size carcasses in different amounts of vegetation cover. These determinations were made by 1) planting fresh carcasses of birds of various sizes and placing camera traps on them to identify scavenger species and the exact time of carcass removal, and 2) planting both carcasses and feather spots of different sizes in different vegetation classes while regular weekly and repeat surveys were taking place. Searcher-efficiency and carcass-removal rates were then used to adjust the annual count of fatalities to arrive at a site-wide fatality estimate.

Results and Discussion

Mean time to scavenging for all placed carcasses was 3.3 days and ranged from as little as 7 minutes to as long as 53 days. The carcass that persisted for 53 days was an outlier by 31 days; after removing this outlier from the analysis the mean time to scavenging was 2.8 days. Within 24 hours of placement, 54.4% of carcasses had been scavenged and 26.3% had been removed entirely (with no trace evidence). Within 7 days of placement, 86.9% of the carcasses had been scavenged, and 38.4% had been removed entirely. Ravens were the most common scavenger, and scavenged more than half of the carcasses placed. Ravens also scavenged carcasses the fastest, with a mean time to scavenging of 2.5 days (and a mean time of 1.5 days with the 53-day outlier dropped). Ravens scavenged three carcasses less than 1 hour after placement, and 72.5% of carcasses within 24 hours. San Joaquin kit foxes scavenged 20 carcasses, and had the second fastest scavenging time, with a mean time to scavenging of 3.6 days.

Of the carcasses placed, small carcasses were scavenged more quickly than large carcasses and more likely to be completely removed (80.6% of small birds scavenged were completely removed compared to 22.2% for large birds); consequently, only 19.5% of the small carcasses removed left evidence (partial carcass or feather spot) of the fatality, whereas, 77.7% of the large carcasses scavenged left evidence of the fatality. A logical extension of this finding is that the creation of a feather spot when a bird is preyed upon by an avian or mammalian predator is likely to occur at least as often as the creation of a feather spot during a scavenging event and feather spots created by depredated birds are likely to persist and be detected during searches at rates equal to feather spots created from scavenged carcasses.

The persistence of carcasses in the environment varied by season and Project element; carcasses placed in the control plots were scavenged more quickly than those along the Gen-tie Line, and carcasses placed in the arrays had the longest persistence time prior to being scavenged.

During the reporting period, searchers detected 94 of 177 (53%) of the fatality plants that were randomly placed in operational arrays, control plots, underneath overhead lines, and along fence lines across the CVSR Project site. Overall, searcher detection rates were higher below overhead lines and along fencelines (56%) than rates in the solar panel arrays (50%). Furthermore, the detection rate in surveyed rows within the arrays was slightly higher than in un-surveyed rows, which is expected as detectability generally declines with distance from the observer. Searcher efficiency was greatest during winter months (63%) and for large–sized carcasses (61% efficiency as opposed to 43% for small sized sparrows). Carcass size and visibility class, based on vegetation height and cover, were the most important indicators of how well searchers located fatalities. Scent detection dogs could be used to increase searcher efficiency rates, particularly where dense vegetation obscures fatalities, to improve the precision of the fatality estimates. If scent dogs prove significantly better during bias trials, we recommend considering the use of scent dogs to conduct fatality searches.

Causes of death were often difficult or impossible to determine from feather spots and carcasses found in the arrays. In a few cases, carcasses were found with no apparent injuries; in other cases, injuries (e.g., broken necks) indicated that a collision was the cause of death. Determining the cause of death from feather spots was even more difficult. We found feather spots on the ground near panels and on panels themselves. Fatalities may have occurred as a direct or indirect result of the presence of solar panels (e.g., a bird stunned by a collision with a panel can then be more easily predated), or they may indicate direct mammalian or avian predation. Solar panels likely contribute to direct and indirect causes of death for birds, but in many cases, it was not possible to determine cause of death. Because the ratio of feather spots to found carcasses was 20:3 during the reporting period, the inability to partition feather spots associated with collisions and feather spots stemming from predation has important implications regarding inferences that can be drawn from the fatality estimate.

Accounting for the spatial organization of avian fatalities is an important aspect of designing surveys and making decisions about future sampling, monitoring, and avoidance and minimization strategies. The geostatistical analysis of the dispersion of avian fatalities in Array 1 and Array 2 separately sampled at 100%, as well as in both arrays combined, indicates that the dispersion of fatalities is not significantly different from a random distribution. Knowing that fatalities are randomly distributed within arrays at the Project site is important for designing future sampling because there are no observable high concentrations (clumping) of avian fatalities that need to be taken into consideration. Moreover, a random dispersion pattern indicates that the probability of detecting an avian fatality should not change as a function of the amount of area (or number of tracker units) searched.

We used the fatality values from Arrays 1 and 2, which were searched in their entirety during the reporting period, to determine how the proportion of each array surveyed affects the accuracy of fatality estimates and confidence intervals.. Given the random dispersion of avian fatalities seen during the study period, and the error analysis for a given area searched, we recommend reducing monitoring to 20% of the total area in each array or array group. Also, each surveyed sample should comprise 30–35 tracker units; to meet this requirement, small arrays (e.g., Array 5) should be grouped with other small, neighboring arrays so that 20% of a given set comprises at least 30 tracker units.

On this Project site, fatalities rates were not high enough to obtain accurate samples during 1-day and 5-day repeat surveys from such small survey areas. As a result, we recommend discontinuing the 1-day and 5-day repeat surveys. We recommend that daily searches generally not be conducted to obtain a fatality estimate because they are labor intensive and labor is generally offset by surveying smaller areas. Given the tradeoff between area covered and frequency of searches, it is better to conduct regular weekly searches of a larger proportion of the site. Daily searches would be most useful if they are necessary to answer specific research questions, for example linking fatalities to weather patterns or to test a deterrent method or some other form of mitigation where knowing more precise timing of fatalities is important, but data gathered for answering these questions should not be used to obtain a site-wide estimate.

We recommend avoiding multiple searches of the same area at different time intervals. If surveys are conducted at various search intervals on the same area to answer research questions, we recommend that the different search strategies be designed to avoid interfering with each other. For example, daily searchers would not collect fatalities so they will still be present for weekly searchers to find.

A total of 357 fatalities were found during surveys of Project elements between 16 August 2012 and 15 August 2013; and an additional 11 fatalities were observed during surveys of control plots within conservation lands. It is important to note that this total comprises observations obtained during clearance surveys, weekly surveys, and 1-day and 5-day repeat surveys. The total number of fatalities observed at various Project Elements, consequently, may be larger than the sample sizes used to conduct overall fatality estimates for Project Elements because fatalities older than the search interval and fatalities found during clearance surveys and 5-day repeat surveys are not used to calculate the overall fatality estimates. Fatality estimates based on weekly searches and 5-day repeat searches were calculated separately.

The majority of fatality species represented year-round avian residents. In total, we found fatalities of 31 different avian species. Nearly all of the species utilize a terrestrial foraging zone; the two exceptions were a single American coot (*Fulica americana*) found along the Gen-tie and a single tree swallow (*Tachycineta bicolor*) found within a control plot. Horned larks, house finches (*Carpodacus mexicanus*), and mourning doves accounted for the greatest proportion of fatalities. Horned larks and mourning doves commonly roost and nest under the solar panels, and the two species combined represent 63% of the total number of fatalities found within the arrays. Documented special-status species fatalities comprised burrowing owl (*Athene cunicularia*), short-eared owl (*Asio flammeus*), long-eared owl (*Asio otus*), and loggerhead shrike (*Lanius ludovicianus*) fatalities. The total count of special-status species fatalities was small compared to the overall count.

In general, we estimated fatalities to be more abundant in the spring and less in the summer. This pattern is likely associated with the peak avian activity in the spring and the subsequent decline in activity in the summer, both documented through onsite avian point counts (HTH 2013). Because birds were more active on the Project site in spring, predation rates and collision rates are likely to be higher.

The Gen-tie Line was the only Project element that was searched for a full year during this reporting period because Project construction was completed during 2012. Eighty-three fatalities were found along the Gen-tie line and, based upon scavenging rates and searcher efficiency, we estimated that 446 fatalities occurred along the Gen-tie during this reporting period. We recommend that linear controls should be used to evaluate fatality rates along both the Gen-tie and MVOH Lines. Point counts targeting both raptors and passerines should be conducted in arrays and along linear features, allowing comparisons to data on activity on the Conservation Lands. These counts and comparisons would indicate whether fatality rates are associated with species abundance.

Project elements became operational and began to be searched at different times of the year, and the number of tracker units surveyed differed among arrays. Therefore, direct comparisons of fatality rates among and between Project elements are not made in this first year's fatality report. At the conclusion of all fatality searches next year, HTH will have collected enough data to report on seasonal differences in fatality rates, differences among arrays, and estimated fatalities per megawatt (a measure of avian and bat impacts that can be used to compare effects among various energy generation facilities).

We estimated that 231 fatalities occurred over a full year in Array 1 (90% confidence intervals: 162, 382) based on 47 fatalities found, and 187 fatalities in the control plots (90% confidence intervals: 107, 367) based on 11 fatalities found. This resulted in an adjusted fatality range 90% confidence interval of 55-275 attributable to the array, or 0.83 to 4.167 fatalities per tracker per year. This corresponds to a mean rate of 7.34 (90% Confidence interval: 3.24 to 16.27 fatalities per MW per year, assuming 0.256MW per tracker).

There are several caveats to keep in mind when interpreting these estimates. As we reanalyze data with full years of surveys for the remaining arrays and control plots these estimates will likely change. Our sample area of control plots in this calculation was based on surveys of 22 tracker sized control plots, which we now know from resampling is a low sample size to calculate fatality rates from, especially for an area as large as the on-site conservation land at the CVSR Project. This is also a conservative adjustment, using only the lower bound of the confidence interval or minimum estimated number of background fatalities.

As we complete full years of surveys for the remaining arrays, this estimate will likely change. Furthermore, because the ratio of feather spots to found carcasses was 20:3 during the reporting period, the inability to partition feather spots associated with collisions and feather spots stemming from predation has important implications regarding inferences that can be drawn from the fatality estimate. We are examining relationships within the existing data set in an attempt to quantify the relative contribution of predation events to the overall fatality estimates.

Section 1.0 Introduction

Through adoption of Resolution #2011-119, the Board of Supervisors of San Luis Obispo County (the County) approved the California Valley Solar Ranch Project (CVSR Project) Conditional Use Permit (DRC 2008-00097) on 19 April 2011. The Conditional Use Permit is subject to the Conditions of Approval (COAs) set forth in Exhibit 6 attached to the Resolution.

The Conditional Use Permit allows High Plains Ranch II, LLC (and any successor in interest for the life of the CVSR Project) to construct and operate a 250-megawatt photovoltaic solar power plant within an approximately 4685-acre site (Project site), located mostly south of State Route (SR) 58, about 6.4 kilometers (km) east of Soda Lake Road, immediately north of the California Valley subdivision, in the Shandon-Carrizo planning area of San Luis Obispo County (Figure 1).

COA #58 of the Conditional Use Permit requires an Avian and Bat Protection Plan (ABPP) and an annual report detailing any Project-related bird or bat deaths or injuries detected during the monitoring study defined in COA #58c. To satisfy COA #58c, H. T. Harvey & Associates (HTH), on behalf of High Plains Ranch II, LLC, has prepared this postconstruction fatality report, which documents the number of avian and bat fatalities counted during Project postconstruction monitoring between 16 August 2012 and 15 August 2013.

One of the primary goals of this report is to provide estimates of the numbers of fatalities associated with different Project elements. To meet this objective, we used the Fatality Estimator (Huso 2010). In addition to performing regular weekly searches, we conducted searcher-efficiency trials to estimate the percentage of fatalities of different sizes found by searchers in both short and tall vegetation. To calculate the persistence of fatalities in the environment, we also conducted carcass-removal trials. The values we derived from both carcass-removal trials and searcher-efficiency trials were used in tandem with the results of our regular weekly searches to calculate estimated ranges of fatalities associated with different Project elements. Additionally, to obtain an estimate of background mortality levels, we conducted controlled searches in control plots located in onsite Conservation Lands. Finally, as a secondary, independent measure of fatalities, we conducted a series of repeat searches with more highly concentrated search intervals. This annual report presents methods, results, and a discussion of the searcher-efficiency trials, carcass-removal trials, regular weekly fatality searches, and all repeat fatality searches. Project elements searched during the reporting period were the Generation-tie (Gen-tie) Line; the Medium-voltage Overhead (MVOH) Line; Arrays 1, 2, 4, 5, and 8; the perimeter fences; and control plots associated with Arrays 1, 2, 4, and 8.

To determine the appropriate amount of sample area in which to conduct fatality searches for estimating total fatalities per year, we considered whether the spatial distribution of detected fatalities, as well as their temporal persistence, may vary according to the amount of area searched (or total number of tracker units searched). (Each tracker unit comprises 18 rows of solar panels, with 40 panels to a row.) Because of the complete survey effort (100% coverage) focused on Arrays 1 and 2 over the course of an entire year, we were able to provide a statistical assessment of how reduced area covered influences the uncertainty around our estimates, and recommend a level of survey coverage that would provide reasonable estimates).

Section 2.0 Methods

2.1 Field Methods

2.1.1 Weekly Fatality Searches

To estimate the total number of fatalities associated with different Project elements during the reporting period, we conducted a series of weekly fatality searches on different Project elements. Because the construction of different Project elements was completed at different times, fatality searches began at varying times in the year, depending on the Project element searched (Table 1). We documented a fatality event each time a carcass or a feather spot was found. We considered a feather spot a fatality if it had at least two or more primary flight feathers, five or more tail feathers, or ten or more feathers of any type concentrated together in an area 1 square meter (m^2) or smaller (Smallwood 2007).

Preening spots often have fewer feathers and are more spread out than feather spots associated with fatalities. Roosting areas rarely contain primary or secondary feathers, but are often dotted with droppings. In the solar arrays, we regularly observed flocks of mourning doves (*Zenaida macroura)*, and horned larks (*Eremophila alpestris*) roosting. Mourning doves exhibit a complex molt strategy, which can occur year round and includes preformative, prealternate, and definitive prebasic molts (Otis et al. 2008). Likewise, horned lark adults and first-year birds undergo a definitive prebasic molt at the end of the breeding season (typically the end of July) (Beason 1995). Searchers used their biological knowledge to determine whether or not feathers from mourning doves, horned larks, or other species known to be in a molt period should be recorded as a fatality. When feathers were determined to be part of a molt or roost spot, no data were taken.

We gave each fatality a unique incident number. Incident numbers were written as follows: YYYYMMDD-#. Each searcher recorded a unique set of numbers, so data can be traced back to individual searchers. To further verify species identifications, we took photos of each fatality, and when necessary, we consulted Scott and McFarland's Bird Feathers identification book (2010). For each fatality, we recorded location (using Universal Transverse Mercator [UTM] coordinates), time found, taxon, common name, four-letter alpha code, carcass condition, parts found, number and types of feathers, and estimated time since death. Whenever possible, we recorded information about the age and sex of the fatality, as well as scavenger type. Additionally, we gathered information on the size and spread of the feather spot and the surrounding substrate, vegetation height, and percent vegetation cover, as well as whether the fatality occurred in a searcher or non-searcher row (for fatalities found in the arrays). All carcasses and feather spots discovered by regular weekly searchers were removed.

Table 1. Fatality Search Commencement Dates by Project Element

Project Element	Date Fatality Searches Began	Survey Period (Days)
Gen-tie Line	6 June 2012	435
Array 1	20 September 2012	329
Array 2 (Serengeti portion only)	25 September 2012	63
Array 1 control plot	1 November 2012	287
Array 1 and 2 fence	25 September 2012	324
Array 2 North (including Serengeti) and South	27 November 2012	261
Array 2 control plot	30 October 2012	289
Array 8 (20% sample)	7 January 2013	220
Array 4 (20% sample)	9 January 2013	218
Array 4 control plots	6 February 2013	190
Array 4 fence (20% sample)	16 January 2013	211
Array 5 and fence (20% sample)	9 January 2013	218
MVOH Line	30 January 2013	197
Array 8 control plots	4 February 2013	192
Array 8 fence (20% sample)	20 May 2013	87

Note: The Serengeti portion of Array 2 was searched separately only until 27 November 2012, so the Survey period reflects the time when the Serengeti portion was sampled separately from the rest of Array2.

Weekly fatality searches were performed along the Gen-tie Line; MVOH Line; Arrays 1, 2, 4, 5, and 8; and the associated control plots and fences for each array. The design comprised sampling 100% of Array 1 and 2, Gen-tie line, MVOH line, and fences for Array 1 and 2. Twenty percent of Array 4, 5, and 8 were sampled as were the fences for Array 4, 5, and 8. Each week, we selected random start locations for each Project element using a random number generator. Random selection was based on tower numbers (for the Gen-tie Line), line segment (for the MVOH Line), numbered array corners (for the solar arrays), and numbered fence corners (for the perimeter fence).

A team of two biologists searched a 30-meter (m)-wide transect centered under the complete length of the Gen-tie Line. Because of the relatively shorter height of the MVOH Line, it was assumed that carcasses would have less potential to distribute over a wide area (HTH 2011); therefore, the transect area along the entire length of the MVOH Line was only 18 m wide. Each person searched half the transect width and half the tower or pole radial areas for both the Gen-tie and MVOH Lines. On the Gen-tie Line, each person searched a 15-m-wide transect for large birds and a 6-m-wide transect for small birds and bats. On the MVOH Line, each person searched a 9-m-wide transect for small and large birds.

In the arrays, biologists searched tracker units in teams of two. In each tracker unit, biologists walked into every other row of panels and visually scanned both the row walked and each adjacent row. To avoid crossing the drive arms of the tracker units, searchers turned around upon reaching the drive arm, and continued to scan the next row as they proceeded out of the row. Thus, although searchers walked only every other row, they visually scanned adjacent rows to ensure full coverage.

To determine background rates of mortality, control plots were established on adjacent onsite Conservation Lands (plots were within 1 km of Arrays 1, 2, 4, and 8). Each control plot had the same dimensions as a tracker unit (i.e. equivalent to 18 rows of solar panels, with 40 panels to a row). We used pin flags or wooden stakes to delineate mock panel trackers on the control plots, and searchers followed the same pattern and procedure used for searching the arrays. Control plots were not established for the 20% sample of Array 5 because the 20% search area for this array contained too few trackers to meet the control plot establishment guidelines set forth in the Avian and Bat Fatality Monitoring Plan for the California Valley Solar Ranch (Appendix A *in* HTH 2011; one control plot for 16 tracker units searched).

Fence segments surveyed for Arrays 1, 2, 4, 5, and 8 (100% of Array 1 and 2 fences, and 20% of Array 4, 5, and 8 fences) were each searched by one biologist. Each week, the biologist walked the inside portion of the fence while scanning a 6-m-wide belt centered on the fence. In some cases, the fences were not completely built until after weekly searches had already commenced. In these instances, fences were included only as part of the regular search routine after they were completely installed.

Because searches were conducted only on designated days as a part of the search protocol, a “make-up” search was not conducted if the search day was missed because of inclement weather. For estimating the total number of fatalities, the fatality model accounted for search intervals of different lengths due to missed surveys (e.g., if a weekly search day was cancelled because of rain, the search effort would resume the following week and for that search, the interval was 14 days, not 7 days).

2.1.1 5-day Repeat Surveys

In addition to regular weekly searches, two types of repeat surveys were conducted. The 5-day repeat surveys were designed to serve several functions: (1) to identify a portion of the fatalities missed by regular weekly searchers, (2) to give limited estimates of the permanence of both feather spots and carcasses, (3) to provide an independent estimate of site-wide fatalities, and (4) to help estimate carcass deposition rates. Five-day repeat surveys were conducted on all Project elements subject to regular weekly searches, with the exception of the Gen-tie Line, which was not included in the 5-day repeat surveys because it was assumed that small birds and bats would be unlikely to strike high-tension powerlines. Each of the remaining sites was subjected to 5-day repeat surveys once every 4 weeks, and surveys were organized so that a 5-day repeat was conducted for a different site each week.

During each 5-day repeat survey period, searchers covered the same 25% (Array 1, Array 2, and MVOH Line) or 5% (Arrays 4, 5, and 8) portion of a given Project element for 5 consecutive days. Repeat searches of arrays also included searches of associated perimeter fences and control plots. However, because of the size of Array 2 and staffing limitations, conducting a 5-day survey of both Array 2 Serengeti and Array 2 North and South was not feasible. Therefore, these portions of Array 2 were treated as separate sites for the purposes of 5-day repeat surveys.

Five-day repeat surveys were originally conducted in the same areas as regular weekly searches for all arrays. However, in June 2013, this protocol was changed, and new, non-overlapping areas were established for 5-day repeat surveys in Arrays 4, 5, and 8, to keep the search interval at a constant span of 7 days for all weekly searches. In Arrays 1 and 2, however, overlapping search areas were unavoidable because weekly searches encompass 100% of the arrays. Under the revised protocol, feather spots and scavenged carcasses were still collected on the fifth day of each 5-day repeat survey, but any intact carcasses found were used in the carcass-removal trials, and camera traps were placed by the carcasses to record the activity of scavengers and monitor the persistence of the carcass past the 5-day span of the repeat survey. Then, the first day of each 5-day repeat survey was treated as a clearance search, and all fatalities found on the first day were removed from further analysis.

2.1.2 1-day Repeat Surveys

One-day repeats (carcass-detectability bias-correction surveys) represent a second type of repeat search, designed to identify a portion of the fatalities missed by weekly searchers. Every other week, a 1-day repeat survey was conducted on the day following regular weekly searches. One-day repeat searches were also conducted after each 5-day repeat survey on either the last day of the 5-day survey or 1 day after completion of the 5-day survey. These repeat searches were conducted to provide further estimates of the detectability of small bird and bat carcasses. Each 1-day repeat survey covered a randomly selected 25% of all elements searched in the weekly or 5-day repeat survey. For example, the 1-day repeat survey of Array 2 included a search of 25% of the array, 25% of the fence, and 25% of the associated control plots.

2.1.3 Searcher-efficiency Trials

To calculate searcher efficiency (i.e., searchers' rate of success in detecting fatalities), we conducted a total of 22 searcher-efficiency trials between 5 September 2012 and 25 September 2013 (Table 2). Although several of these trials fall outside of the current reporting period for fatalities, we include the trial result herein because these data were essential to our overall fatality estimates.

Season was assumed to be a potential influence on searcher efficiency. Within the reporting period, we defined four unique seasons as follows: fall (16 August to 15 November), winter (16 November to 15 February), spring (16 February to 15 May), and summer (16 May to 15 August). We were excluded from operational arrays of the Project site between 26 June and 17 July 2013 for maintenance reasons; therefore, no searcher-efficiency trials were conducted during this period.

Table 2. Searcher-efficiency Trial Date, Associated Season, and Location

Date	Season	Location(s)
5 September 2012	Fall	Gen-tie Line
26 September 2012	Fall	Gen-tie Line
18 December 2012	Winter	Array 2
29 January 2013	Winter	Array 2
28 February 2013	Spring	Array 1
17 March 2013	Spring	MVOH Line
15 May 2013	Spring	Arrays 2 and 4; control plots
23 May 2013	Summer	Array 1; control plots; Gen-tie Line
31 May 2013	Summer	Arrays 4, 5, and 8; control plots; Gen-tie Line
5 June 2013	Summer	MVOH Line
11 June 2013	Summer	Array 2
20 June 2013	Summer	Array 1
8 August 2013	Summer	Arrays 1 and 2
22 August 2013	Fall	Arrays 1, 4, and 5
26 August 2013	Fall	Array 8
11 September 2013	Fall	Arrays 4 and 5; control plots; Gen-tie Line; MVOH Line
16 September 2013	Fall	Arrays 4, 5, and 8; control plots
17 September 2013	Fall	Arrays 2, 4, 5, and 8; control plots
18 September 2013	Fall	Arrays 4 and 5; Gen-tie Line; MVOH Line
19 September 2013	Fall	Arrays 1, 4, 5, and 8
20 September 2013	Fall	Arrays 4, 5, and 8
25 September 2013	Fall	Arrays 4 and 5; Gen-tie Line; MVOH Line

Each week during which searcher-efficiency trials were scheduled, we set out between two and eight "fatality plants" (i.e., carcasses or feather spots) in areas scheduled for searches. We arrived approximately 1 hour in advance of the searchers so that we could set out fatality plants without alerting the regular searchers they were being tested. We recorded a Global Positioning System (GPS) point for each fatality plant. We marked each fatality discreetly with tape or flagging so that searchers would know to report their finds as part of the controlled searcher-efficiency trial. We randomly selected locations for the fatality plants within the tracker units, control plots, and along the overhead lines and fences. Within the tracker units and control plots, we randomized placement between surveyed and un-surveyed rows, as well as with regard to distance and direction from structures.

During the week of 16–20 September 2013, we set out 10 to 40 fatality plants each day to capture missing combinations of explanatory variables (e.g., large feather spots in medium vegetation cover), which were needed to correctly assess our final fatality estimates for the Project site, but were not adequately sampled in previous searcher-efficiency trials. For this period, we used a stratified random sampling scheme: we purposefully selected predetermined habitat categories to increase the sample size for our overall parameter estimates in our final fatality model.

We used a total of 177 fatality plants (90 carcasses and 87 feather spots) throughout the course of all trials. The fatality plants were specimens of common species found on the CVSR Project site (Appendix A).

2.1.4 Carcass-removal Trials

To estimate how long carcasses persist in the environment (which influences their continued detectability over time), we conducted carcass-removal trials. We acquired avian carcasses from the onsite fatality searches and wildlife rehabilitation centers, and also collected them opportunistically (e.g., collected road-killed birds) under state and federal salvage permits. Whenever possible, we used species that naturally occurred on the site or in the surrounding area. Once a carcass was acquired, we limited its handling to reduce transfer of foreign scents to the carcass. We marked carcasses by attaching electrical tape or flagging to one leg, to differentiate them from naturally occurring fatalities. We varied the body sizes of carcasses to determine carcass-removal rates and scavenging outcomes for different sizes. Of the 99 carcasses that we placed, 62 were large (>100 grams [g]) and 37 were small (<100 g) (Appendix B).

Initially we placed carcasses at randomly chosen locations along the Gen-tie Line, in Arrays 1 and 2, and their associated control plots. After construction was completed for additional elements (i.e., arrays and the MVOH lines), carcass removal trials were also conducted in all those search area elements. We dropped carcasses from shoulder height and allowed them to fall naturally to the ground. We recorded each carcass location with a GPS unit, noted the direction and distance to the nearest tower (when carcasses were placed along the Gen-tie Line) or tracker number (when carcasses were placed in arrays). We took photos to document the position of the carcass. We placed Bushnell Trophy Cameras (Model 119436) within 1–1.5 m of the carcass on a t-post, facing north to avoid allowing sunlight to shine directly into the camera lens. To avoid "scavenger swamping" (saturating our study area with more carcasses than resident scavengers have the ability to remove) (Smallwood et al. 2010), we limited the number of carcasses in a search area at one time to four. We programmed cameras to take three pictures in quick succession after each trigger event; each camera had a 1-second refractory period. Each picture was stamped with the date and time.

We checked each carcass at least once per week, for up to 6 weeks, or until it was scavenged. If the carcass was scavenged, we collected all remaining feathers and signs of the carcass and removed the camera. We classified the carcass as removed if the carcass could not be located, and there were fewer than ten feathers of any type or fewer than two primary feathers remaining. To classify feather spots, we used the same criteria as regular weekly searchers. Therefore, we classified the scavenging outcome as "not removed" if there were ten or more feathers of any type, or two or more primary feathers or any flesh or bone remaining. If the carcass was no longer in front of the camera and was not readily apparent, we searched the surrounding area using a spiral search pattern. We started the search at the camera's location and spiraled out to 30 m from the camera. If the carcass had been moved to a new location within the search area, but was intact, we repositioned the camera on the carcass in its new location. At least once per week, we checked the camera batteries and Secure Digital (SD) memory storage cards. We replaced the batteries when there was less than half of the charge remaining, and we replaced the SD card when there were more than 2000 pictures.

For 22 of the carcasses that were removed, the time of scavenging was not captured by camera. For these carcasses, we recorded the time the carcass was last photographed and the first time a photograph was taken without the carcass present. For the purpose of our descriptive statistics, we then calculated the midpoint between these two times and used that as the time of scavenging.

2.2 Statistical Methods

Several issues must be considered when estimating fatalities. First, animals die at an unknown rate; the rate must be inferred from regular searches of a site. Second, fatalities persist for varying amounts of time. Third, fatalities are imperfectly detected by searchers. The need to accurately estimate fatalities given these variables has driven the development of several fatality estimation statistical methods (e.g., see Johnson et al. 2003, Smallwood 2007, and Huso 2010). All of these fatality estimation methods share a similar underlying model. Generally, the fatality estimation for a given site may be written as:

$$F=C/rp,$$

where the number of fatalities, F, is the quotient of the number of carcasses found, C, over the product of carcasses left unscavenged, r, and the proportion that an observer sees, p (Huso 2010).

The inputs for r and p are estimated in subgroups of covariates that will influence the detectability and persistence of each carcass, such as carcass size, vegetation height, and stage of decay or scavenging (i.e., feather spot versus carcass). Given the tendency for many fatality models to underestimate site-wide fatalities, we chose to use a fatality estimator written by Huso (2010), which was shown to outperform previous fatality estimation models by more accurately accounting for imperfect detectability. This model, the Fatality Estimator, was developed to estimate fatalities primarily for wind energy projects; however, it can be applied to other sources of fatalities, including powerlines and solar projects (Huso 2010). The estimator uses this conceptual framework of fatalities, combined with "bootstrapping" from models of r and p, to calculate variances and confidence intervals for estimates of fatalities. Bootstrapping is a statistical method used to create a distribution to assign measures of variance to estimates that use data for which the underlying distribution is either unknown or cannot be represented algebraically (Efron and Tibshirani 1986). Bootstrapping resamples the data with replacement, several thousand times, to create a distribution that may be used to infer information about the sample mean.

2.2.1 Estimating Carcass-removal Rates

We assessed carcass-removal rates using the following descriptive categories: seasonality, scavenger species, size of carcass, and search area.

Measurements of carcass-removal rates typically include one or more censoring values. A censoring value is used in statistics when a value is only partially known. For example, if a carcass was checked on day 7 and was present, and was checked again on day 10, and found to be missing, then the date of scavenging is unknown, and an interval censor would be used. Because we used camera traps, most scavenging times were known precisely, so data were not censored. However, for the 22 carcasses for which the moment of scavenging was not recorded, we applied interval censoring. Additionally, we applied right censoring to the carcasses that were removed but left feather spots behind, because the extended persistence time of the feather spots was unknown. Specifically, we assumed that all small feather spots (i.e., feather spots left from a small carcass) would last at least 15 days, and large feather spots would last at least 30 days, beyond scavenging.

There are four commonly used distributions of survival models that can be used in the Fatality Estimator for a value of *r*: exponential, Weibull, loglogistic, and lognormal. These four distributions have different rates and shapes of decay curves that attempt to model the survival of carcasses over a given search interval. We used Akaike's Information Criterion (AIC), corrected for finite sample size (AICc; Akaike 1973), to rank the fit of each survival model to our carcass-removal trial data. Because the time of death for found fatalities is unknown, the probability of persistence cannot be calculated exactly for each carcass, but it can be estimated from the selected survival model and bootstrapped to obtain a range of estimates of *r* for each carcass. Because of issues regarding our sample size of covariate combinations, we modeled carcass-removal time only as a function of carcass size.

2.2.2 Estimating Searcher Efficiency

The proportion of fatalities that an observer sees, *p*, is represented most simply by the following equation:

$$p = \frac{NumberObserved}{NumberAvailable}$$

The value of *p* may be affected by several covariates. Therefore, we calculated detection rates for the following descriptive categories and combinations thereof: seasonality, Project element type (i.e., arrays and lines), visibility (i.e., habitat characteristics), and the size of each carcass or feather spot that was planted.

To determine which of the above explanatory variables (or combinations of) best described detection rates, we compared multiple models within the Fatality Estimator statistical software (Huso 2010) using AICc. Beginning with a null model (no temporal or categorical variation), we used a bottom-up modeling approach to compare AIC values and find the most appropriate model structure by incorporating different combinations of explanatory variables.

We calculated detection as the proportion of found fatality plants over the total available number of plants. Any fatality plant removed by scavengers before biologists searched the area was not included in the analysis. We assessed detection rates temporally, spatially, and categorically.

Based on the search method used (i.e., line transects under overhead lines and along fencelines, versus patterned searches within rows in arrays), we grouped fatality plants together. Those in arrays and control plots were grouped together, and those along the overhead lines (i.e., the Gen-tie and MVOH Lines) and fence lines surrounding searched arrays were grouped together.

We analyzed the two fall periods (2012 and 2013) together. Only one period of data was available for each of the winter, spring, and summer seasons.

We assessed habitat characteristics (i.e., vegetation height and percent cover) within a 1-m^2 area surrounding each fatality plant to test detection rates based upon visibility. We initially categorized visibility into three classes, easy, moderate, or difficult visibility, based on vegetation height and percent cover (Table 3), however, once trials began, we realized that the abundance of difficult visibility classes on the site were very limited; therefore, for all analyses, we grouped moderate and difficult visibility classes together (Figure 2).

Table 3. Visibility Classifications Assigned to Categories of Vegetation Height and Cover

Vegetation Height	Vegetation Cover (%)	Classification
Low	0–50	Easy
Low	50–100	Moderate
Medium	0–25	Easy
Medium	25–100	Moderate
High	0–50	Moderate
High	50–100	Difficult

a) Easy Visibility **b) Medium Visibility**

Figure 2. Photographic Examples of Easy and Medium Visibility Classes, Based on Vegetation Height and Percent Cover.

We assigned each species of carcass to one of two size classes (small or large) based on weight (i.e., small = <100 g; large = >100 g). We also assigned a size class to each feather spot used as a fatality plant. A small feather spot was defined as feathers from a small to medium-sized bird, scattered sparsely in a ≤20 square centimeter (cm^2) area; a large feather spot was defined as feathers from a large bird in a small area (≤20 cm^2) or feathers from a small to medium-sized bird scattered densely in an area ≥20 cm^2.

2.2.3 Estimating Fatalities on the Project Site

The Fatality Estimator bootstrapping procedure calculates an adjusted fatality value for every fatality found based on search interval, searcher efficiency, and carcass persistence. These bootstrapped values are then summed, and a site total estimate and 90% confidence intervals are calculated for the site and each covariate combination assigned. The Fatality Estimator was developed for wind energy projects, and uses individual wind turbines as the sample unit of replication. To apply this tool to the CVSR Project, we used tracker units instead of turbines as the sample unit. For linear features (overhead lines and fences) where we sampled the entire length, we used the entire feature as the sample unit. For sites in which we searched less than 100% of the area, we divided these values by the proportion of area searched to extrapolate it to the whole array or linear feature.

2.2.3.1 Overall Fatality Estimates

We calculated weekly fatality estimates separately for each Project element. For the arrays, we set the tracker as the unit of replication, and for each array we calculated total estimates of fatalities, fatalities per tracker unit, and 90% confidence intervals. In Array 2, 36 tracker units within the Serengeti portion of the array were searched for 2 months before the rest of the array, so we calculated separate values for that period. For linear features on the site, such as the Gen-tie Line, MVOH Line, and fences, we estimated fatalities for the feature as a whole. Estimates are based on 5000 bootstrapped iterations. We calculated fatality estimates and confidence intervals for large and small birds and particular species, as well as calculating seasonal totals.

Owing to the constraints and assumptions of the Fatality Estimator; appropriately, we did not include every fatality found in our calculations. We did not include fatalities found during clearance surveys (the first survey of an area), or fatalities that we determined to be older than the search interval, because the correction for searcher efficiency does not take into account repeated chances of finding a fatality (Huso pers. comm.).

2.2.3.2 Fatality Estimates from 5-day Repeat Surveys

To calculate fatality estimates from our 5-day repeat surveys, we treated each 5-day period as an independent unit of replication. Because the first day of each search was a clearance survey, each repeat survey period effectively consisted of 4 consecutive search days. We used the Fatality Estimator to calculate fatality estimates and 90% confidence intervals for the search areas of the array covered during repeat surveys. We then divided these estimates and 90% confidence intervals by the proportion of the array searched to extrapolate to the entire array, and then divided this estimate by the proportion of days searched over the total number of days until next search period to extrapolate temporally to the whole month (Huso pers. comm.).

To calculate the rate of deposition of fatalities per tracker units per day, we divided the estimate for each 5-day repeat period by the number of tracker units searched, and by the number of days it was searched.

2.2.3.3 Error Assessment for Sampling Avian Fatalities

To guide future sampling at CVSR, an error assessment was conducted to determine what proportion of arrays should be monitored to determine a reasonable measure of avian fatality. This is the first study that we are aware of designed to estimate the number of avian fatalities at a large utility scale photovoltaic facility. One of the unknowns was what percentage of the entire facility needed to be surveyed to attain a given confidence level for determining an accurate fatality estimate. To collect data to determine this, we surveyed two large arrays, Arrays 1 and 2, with 100% coverage. We continued this level of effort for a full year in case the distribution of fatalities varied significantly by season.

Two steps were involved in developing the error assessment for the survey effort. The first step was to determine the spatial organization of avian fatalities across 100% of the area searched inside the two sample arrays, throughout the entire monitoring period (1 year). We estimated the mean and standard deviation of avian fatalities per tracker unit (each unit of tracking solar panels with 18 rows and 40 solar panels per row) for each array and for both arrays combined. Furthermore, using the individual fatality sampling points, we calculated the Global Moran's I index to characterize the spatial dispersion of avian fatalities within and among arrays. The Global Moran's I index is a direct assessment of the spatial autocorrelation of points in space and provides a statistical measurement indicating whether avian fatalities may be clumped, uniform, or not different from random. We conducted the geostatistical analysis of avian fatalities using ArcInfo version 10.0 and its geographic statistical toolbox.

The next step was to establish the relationship between percent area monitored and the variation in fatality estimates around a true value.. To accomplish this we focused on the coefficient of variation (i.e., "variance-to-mean ratio") as our metric of variation for describing the changes in the number of detected avian fatalities with increasing area searched. Because the coefficient of variation is a normalized measure of dispersion, this metric is well suited for assessing changes in the distribution of avian fatalities as a function of area searched. In other words, it accounts for the clumping of avian fatalities in space (among tracker units within an array) and is a better metric than the mean for describing changes in detection of avian fatalities.

Using the datasets of detected avian fatalities for Arrays 1 and 2, we constructed a statistical resampling function to understand the variation that would be introduced into the final avian fatality estimate by sampling less than the entire array. This function simulates a range of sample sizes (from one tracker unit to one fewer than the total number of tracker units); for each sample size, 3000 simulated data sets were generated from the original data. For each of these data sets, the total number of fatalities was summed. This number was then divided by the values determined to correct for searcher efficiency and carcass persistence time. This number was then scaled to the total number of tracker units per unit area tested (e.g., tracker units in Array 1). We calculated the coefficient of variation for each sample size by dividing the standard deviation of the sample by the mean. All resampling analyses were conducted in the statistical program R, Version 3.0.2 (R Development Core Team 2011).

Section 3.0 Results

3.1 Carcass-removal Trials

Between 15 October 2012 and 12 August 2013, we placed a total of 99 carcasses for carcass-removal trials. We placed camera traps on 95 of these carcasses, and were able to record the exact removal time and scavenger species for 77 (81.1%) of the carcasses placed that had a camera trap. Of the 99 carcasses placed, 43 (43.4%) were eventually removed either completely, or left insufficient evidence to be classified as a fatality in a regular weekly search. The remaining 56 (56.6%) carcasses were scavenged from the original location or within the search area, and left evidence behind in the form of feathers, skin, or a partial carcass.

Mean time to scavenging for all placed carcasses was 3.3 days and ranged from as little as 7 minutes to as long as 53 days (Table 4). The carcass that persisted for 53 days was an outlier by 31 days; the mean time to scavenging without it was 2.8 days. Within 24 hours of placement, 54.4% of carcasses had been scavenged and 26.3% had been removed entirely (with no trace evidence). Within 7 days of placement, 86.9% of the carcasses had been scavenged, and 38.4% had been removed entirely (Table 5).

Table 4. Mean Times and Range for Scavenging for Each of Five Categories: Total, Carcass Size, Season, Scavenger Species, and Search Area

	N	Mean Time to Scavenging (Days)[a]	Range[b]
Total	99	3.3 ± 6.7 (2.8 ± 1.7)[b]	7 min–53 days
Carcass Size			
Large	63	3.5 ± 5.0	7 min–22 days
Small	36	3.0 ± 9.3 (1.5 ± 3.1)	10 min–53 days
Season			
Fall	8	1.2 ± 1.7	2 hours–5.5 days
Winter	16	8.3 ± 12.8 (5.3 ± 5.6)	4 hours–53 days
Spring	40	2.7 ± 4.9	15 min–22 days
Summer	35	2.2 ± 3.0	7 min–12.5 days
Scavenger			
Common raven	51	2.5 ± 8.0 (1.5 ± 3.7)	7 min–53 days
San Joaquin kit fox	20	3.6 ± 4.3	11 hours–16.5 days
Coyote	5	4.5 ± 4.7	8.5 hours–13.5 days
Unknown	22	4.3 ± 5.2	30 min–18 days
Search Area			
Array	49	4.4 ± 8.5 (3.4 ± 4.7)	1.7 hours–53 days
Gen-tie Line	40	2.6 ± 4.4	10 min–18 days
Control plots	10	0.6 ± 0.7	7 min–2 days

Notes: Min = minutes.

[a] Mean time to scavenging is shown ± 1 standard deviation.

[b] Carcass that persisted for 53 days excluded.

[c] (Results) reflect values excluding the carcass that persisted for 53 days.

Table 5. Percentage of Carcasses Scavenged and Removed within 1 Day and 7 Days of Placement, by Body Size, Season, Scavenger, and Placement Area

	N	% Scavenged by 1 Day	% Removed by 1 Day	% Scavenged by 7 Days	% Removed by 7 Days
Total	99	54.4	26.3	86.9	38.8
Carcass size					
Large	63	47.6	7.9	82.5	15.9
Small	36	66.6	58.3	94.4	77.8
Season

Gen-tie	40	62.5	35.0	35.0	87.5
Control plot	10	80.0	30.0	100.0	40.0

3.1.1 Effect of Scavenger Type

With our remote cameras, we were able to document four species of vertebrate scavengers during the carcass-removal trials: San Joaquin kit fox (*Vulpes macrotis mutica)*, common raven (*Corvus corax*), coyote (*Canis latrans*) and turkey vulture (*Cathartes aura*) (Figure 3). Ravens were the most common scavenger, and scavenged more than half of the carcasses placed. Ravens also scavenged carcasses the fastest, with a mean time to scavenging of 2.5 days (and a mean time of 1.5 days with the 53-day outlier dropped). Ravens scavenged three carcasses less than 1 hour after placement, and 72.5% of carcasses within 24 hours. Ninety-four point one percent of raven-scavenging events occurred within 1 week. Of the 51 carcasses scavenged by ravens, 37.3% were removed entirely. In total, ravens scavenged 32 large carcasses and 19 small carcasses.

Figure 3. Scavengers Documented in Carcass-removal Trials

Figure panels are as follows: (top left) a common raven removing a ruby-crowned kinglet 53 days after it was placed in an array, (top right) a San Joaquin kit fox removing a Brewer's blackbird from a control plot 4 days after it was placed, (bottom left) a coyote removing a barn owl carcass after 3 days, and (bottom right) a turkey vulture scavenging a red-tailed hawk carcass 7 days after it was placed.

San Joaquin kit foxes scavenged 20 carcasses, and had the second fastest scavenging time, with a mean time to scavenging of 3.6 days. Within 24 hours, 35% of the San Joaquin kit fox scavenging events had occurred, and 80% had occurred within 7 days (Table 5). San Joaquin kit foxes were more likely than ravens to remove carcasses without leaving trace evidence. Of the 20 carcasses scavenged, 60% were removed entirely (Table 6), and 13 of these were large-bodied birds.

Coyotes had the longest mean time to scavenging: 4.5 days. They scavenged five carcasses in total, all of which were large. In all but one case, there was enough trace evidence left from the scavenged carcass to be considered a fatality.

Finally, our remote cameras captured a turkey vulture scavenging the carcass of a red-tailed hawk (*Buteo jamaicensis*) 7 days after it was originally placed.

For the remaining 22 carcasses, the scavenger responsible was not photographed, because of camera malfunctions.

Table 6. Outcomes of Carcass-removal Trials

	N	Carcasses Removed (%)[a]	Carcasses Leaving Feather Spots (%)	Partial Carcass (%)[b]
Total	99	41.4	35.4	23.2
Carcass Size				
Large	63	22.2	44.4	33.3
Small	36	80.6	13.9	5.6
Season				
Fall	8	75.0	12.5	12.5
Winter	16	56.3	37.5	6.3
Spring	40	32.5	37.5	30.0
Summer	35	42.9	31.4	25.7
Scavenger				
Common raven	51	37.3	33.3	29.4
San Joaquin kit fox	20	60.0	30.0	10.0
Coyote	5	20.0	60.0	20.0
Turkey vulture	1	0.0	0.0	100.0
Search Area				
Array	49	36.7	38.8	24.5
Gen-tie Line	40	52.5	27.5	20.0
Control plots	10	40.0	30.0	30.0

Notes:

[a] "Removed" refers to all carcasses that left no sign, or too few feathers to be classified as a fatality.

[b] "Partial carcasses" are classified as any fatality that was partially removed but left trace amounts of bone or flesh behind.

3.1.2 Effect of Carcass Size

Of the 63 large carcasses we placed, 22.2% were removed entirely or left insufficient evidence to be considered a fatality. The mean time to scavenging for large carcasses was 3.5 days, with 47.6% scavenged within 24 hours and 82.5% scavenged within 7 days. Small carcasses were more likely to be removed: 80.6% were removed. Mean time to scavenging for small carcasses was 3.0 days when the carcass in this size class that persisted for 53 days was included, and 1.5 days when it was excluded. Within 24 hours, 66.6% of small carcasses were scavenged, and within 7 days 94.4% were scavenged.

3.1.3 Effect of Season and Search Area

We put out carcasses for carcass-removal trials during all four seasons, but the coverage across seasons was not equal: eight carcasses were placed in fall, 16 in winter, 40 in spring, and 35 in summer. The mean time to scavenging was longest in fall, and shortest in winter. The carcass that persisted for 53 days was placed in winter, but even after dropping that carcass from the analysis, scavenging time was still longest in winter. Mean scavenging times in spring and summer were 2.7 days and 2.2 days, respectively.

Carcasses placed in the control plots were scavenged more quickly than those along the Gen-tie Line (Figure 3). Carcasses placed in the arrays had the longest time to scavenging: 4.4 days. The carcass that persisted for 53 days was in an array; however, even when this carcass was dropped from the analysis, mean time to scavenging in the arrays was still the longest: 3.4 days.

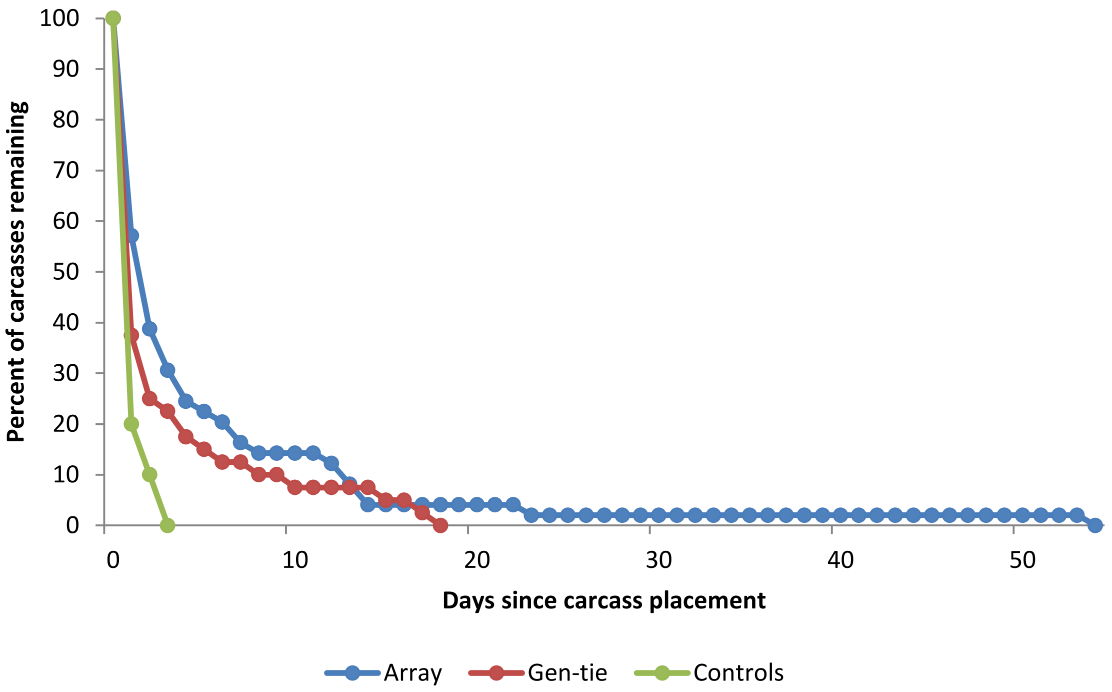

Figure 4. Percentage of Trial Carcasses Remaining Undisturbed by Scavengers per Day, Grouped by Search Area; N=99

3.1.4 Model Selection

Of the four selected survival models compared in the estimator, the lognormal model had the lowest AICc score (Table 7). For large carcasses, based on a search interval of 7 days, $r = 0.92$ (lower confidence interval =

0.86, upper confidence interval = 0.97). For small carcasses, $r = 0.42$ (lower confidence interval = 0.31, upper confidence interval = 0.55).

Table 7. AICc Values for Each of Four Distribution Models of Carcass Persistence

Survival Model for Carcass Persistence	AICc
Lognormal	253.00
Loglogistic	253.44
Weibull	259.44
Exponential	337.72

Because the difference in AICc values for the lognormal and loglogistic models was less than 2, these models were considered statistically equivalent (Akaike 1973), but we chose to use the lognormal model because it had a slightly lower AICc value.

3.2 Searcher-efficiency Rates

3.2.1 Overall Project Site Detection Rates

Over the course of 22 searcher-efficiency trials between September 2012 and September 2013, searchers detected 94 of 177 (53%) of the fatality plants that were randomly placed in operational arrays, control plots, underneath overhead lines, and along fence lines across the CVSR Project site. Small sample sizes in certain seasons prohibited us from using seasons as an explanatory variable for searcher efficiency. Nonetheless, we did see a sharp decrease (23%) in searcher efficiency between winter (N = 8) and spring (N = 10); efficiency then increased by 13% in summer (N = 17).

The detection rate of fatality plants in all areas with easy visibility was slightly higher (56%) than in those areas with medium visibility (51%). Searchers were slightly more efficient at detecting carcasses (56%) than feather spots (51%), and a greater proportion of large-sized fatality plants (61%) were detected by searchers compared to 43% of small-sized fatality plants in all areas (Table 8).

3.2.2 Detection Rates by Area and Explanatory Variables

Searcher detection rates were higher below overhead lines and along fencelines (56%) than rates in the solar panel arrays (50%). The detection rate in surveyed rows was slightly higher than in un-surveyed rows. Detection of fatality plants found in “easy” visibility areas along lines was higher (63%) than in “moderate” visibility areas (49%), but we found the opposite to be true in the arrays, where detectability in moderate areas was 8% greater than in easy areas. The detection rates of large fatality plants in arrays and along lines were essentially the same (approximately 62%), and large fatalities were easier to detect than small fatalities in both arrays (34%) and along lines (47%).

Detection rates within arrays, of large and small fatality plants in easy visibility areas, were 56% and 36%, respectively; these rates were lower than comparable rates along lines. In moderate visibility areas along lines, the detection rate of large fatality plants (48%) was lower than in easy visibility areas (76%), but we found that the detection of small fatality plants in moderate visibility areas along lines was slightly higher (6%) than in easy visibility areas. The detection rate of large fatality plants in moderate visibility areas in arrays (68%) was 20% higher than along lines, but the detection rate of small fatality plants in moderate visibility array areas (31%) was lower than the comparable rate along lines.

Detection rates were consistently higher for both large carcasses and feather spots in easy visibility areas than in moderate visibility areas, with the exception of the detection of small feather spots in medium visibility areas, which was 23% higher than in easy visibility areas.

Table 8. Overall Detection Rates from Searcher-efficiency Trials, September 2012 to September 2013

Category	Detection Rate	95% Confidence Intervals (lower, upper)	N
Overall	0.53	(0.46, 0.60)	177
Fall	0.54	(0.45, 0.62)	142
Winter	0.63	(0.31, 0.86)	8
Spring	0.40	(0.17, 0.69)	10
Summer	0.53	(0.31, 0.74)	17
Arrays/control plots	0.50	(0.40, 0.60)	90
Overhead/fence lines	0.56	(0.46, 0.66)	87
Surveyed row	0.51	(0.37, 0.65)	45
Unsurveyed row	0.45	(0.30, 0.62)	33
Large fatality size	0.61	(0.51, 0.70)	96
Small fatality size	0.43	(0.33, 0.54)	81
Carcass	0.55	(0.45, 0.65)	90
Feather spot	0.52	(0.40, 0.61)	87
Easy visibility	0.56	(0.45, 0.65)	90
Medium visibility	0.51	(0.40, 0.61)	87

Our top model in the Fatality Estimator had an AICc value of 238.55; this model indicated that carcass size best explains searcher-efficiency rates. However, the second best model, which differed by less than 2 (AICc

= 239.98), showed equal support for an additive effect between visibility class and fatality size (Table 9). We therefore adopted the additive effect structure for our detection rate in estimating fatalities, because visibility was shown in our descriptive statistics (see above) to be an important indicator of how well searchers did in locating fatalities.

Table 9. AICc Ranking of Searcher-efficiency Models

Searcher-efficiency Model	Explanatory Variables	AICc
size	Carcass size	238.55
size + visibility	Carcass size and visibility class	239.98
element + size + visibility	Project element, carcass size, and visibility	241.49
size x visibility	Carcass size and visibility class interaction	244.32
size x visibility + element	Carcass size and visibility interaction, and Project element	246
null	Null model	246.71
element	Project element	248.05
visibility	Visibility	248.32

3.3 Summary of Annual Fatalities

3.3.1 Results of Weekly Searches

A total of 357 fatalities were found during surveys of Project elements between 16 August 2012 and 15 August 2013; and an additional 11 fatalities were observed during surveys of control plots (each plot equivalent in size to a tracker unit: 18 rows of solar panels, with 40 panels to a row) within conservation lands (Table 10; Figures 5-9; Appendices C and D). It is important to note that this total comprises observations obtained during clearance surveys, weekly surveys, and 1-day and 5-day repeat surveys. The total number of fatalities observed at various Project Elements, consequently, may be larger than the sample sizes used to conduct overall fatality estimates for Project Elements because fatalities older than the search interval and fatalities found during clearance surveys and 5-day repeat surveys are not used to calculate the overall fatality estimates. Fatality estimates based on weekly searches and 5-day repeat searches were calculated separately.

The majority of fatality species represented year-round avian residents (Figure 10, Appendix D). In total, we found fatalities of 31 different avian species (Figure 11). Nearly all of the species utilize a terrestrial foraging zone; the two exceptions were a single American coot (*Fulica americana*) found along the Gen-tie and a single tree swallow (*Tachycineta bicolor*) found within a control plot (Appendix D). Horned larks, house finches (*Carpodacus mexicanus*), and mourning doves accounted for the greatest proportion of fatalities. Documented special-status species fatalities comprised burrowing owl (*Athene cunicularia*), short-eared owl (*Asio flammeus*), long-eared owl (*Asio otus*), and loggerhead shrike (*Lanius ludovicianus*) fatalities. The total count of special-status species fatalities was small compared to the overall count. One fatality was identified to genus, but not to species. Seven fatalities were not identified because partial skeletons and entrails or covert feathers were all that remained. These seven fatalities were placed into two "unknown" categories (unknown small passerine [6] and unknown [1]). Feather spots accounted for the vast majority of fatalities observed with a ratio of feather spots to carcasses (including partial carcasses) of 20:3.

Table 10. Summary of Avian Fatality Searches Conducted between 16 August 2012 and 15 August 2013; N= 357 for Project Elements, N = 11 for Control Plots

Project Element	Date of First Search	Number of Tracker Units[a] or Distance of Straight Line Search	Total Number of Fatalities Found Across all Survey Methods
Array 1	20 September 2012	66 trackers	52
Serengeti (only)[b]	25 September 2012	36 trackers	8
Array 1 control plots	30 October 2012	8 trackers	3
Array 1–2 fence	25 September 2012	5300 m	11
Array 2 North (including Serengeti) and South	27 November 2012	114 trackers	137
Array 2 control plots	1 November 2012	14 trackers	6
Array 4	9 January 2013	29 trackers	23
Array 4 control plots and fence	6 February 2013	4 trackers; 225-m fence	1 in control plot, 1 on fence
Array 5 and fence	9 January 2013	4 trackers; 56-m fence	5 in array, 0 on fence
Array 8	7 January 2013	54 trackers	13
Array 8 control plots	4 February 2013	6 trackers	1
Array 8 fence	20 May 2013	1600 m	0
Gen-tie Line	6 June 2012	4000 m	90
MVOH Line	30 January 2013	6800 m	17

[a] Tracker unit equals 18 rows of solar panels, with 40 panels to a row.

[b] The Serengeti portion of Array 2 was searched separately only until 27 November 2012, so the number of fatalities reported for the Serengeti reflects this initial period.

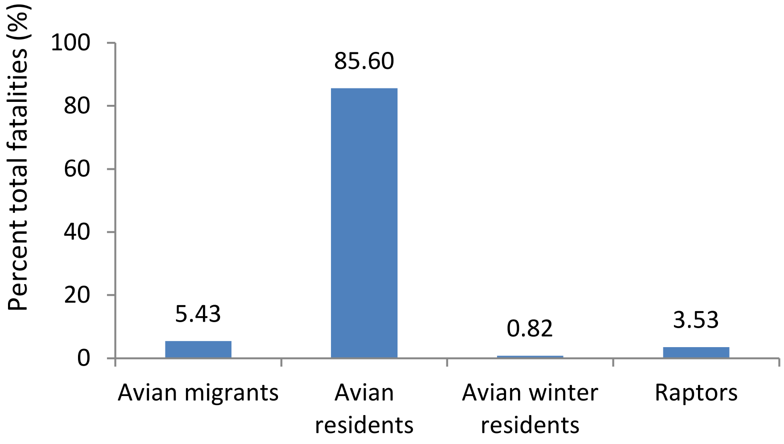

Figure 10. Percent of Total Fatalities in Each of Four Taxonomic Groups; N= 357

Groups were created based on knowledge of species typically found on the Project site at different times of the year.

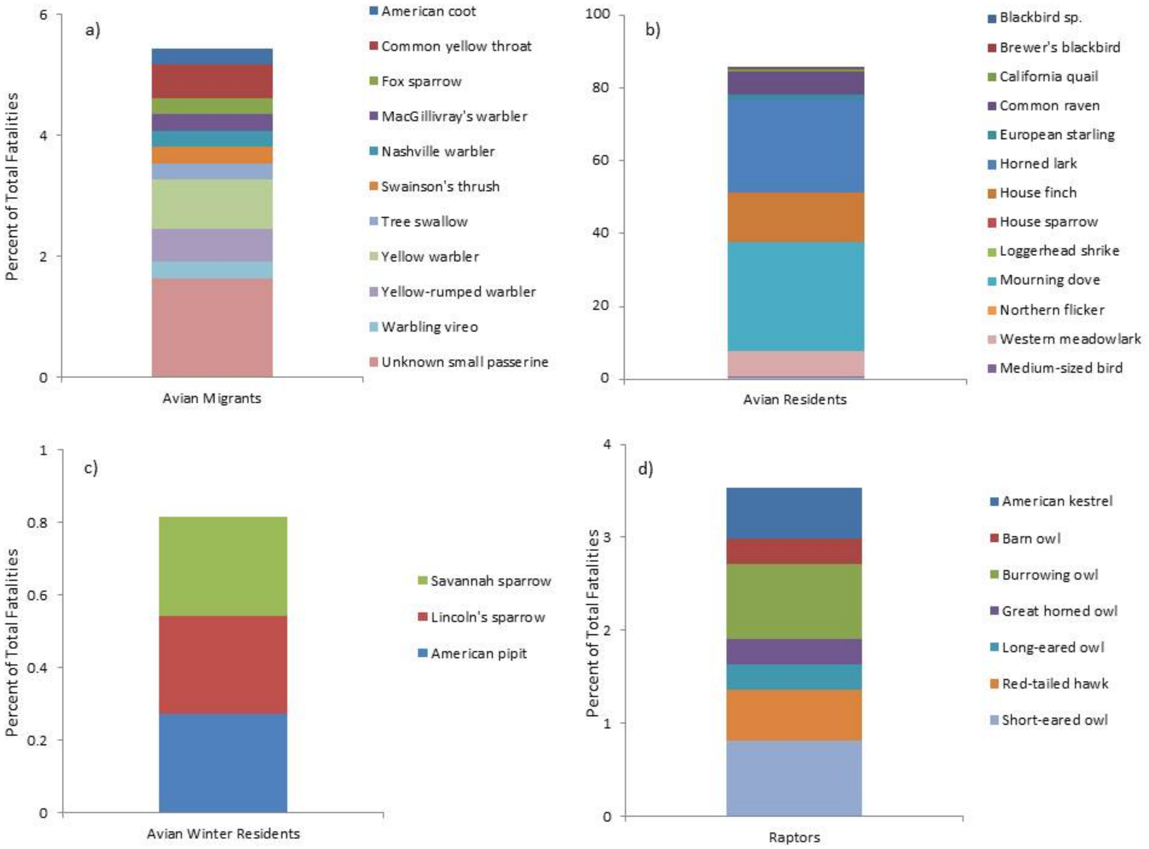

Figure 11. Percentage of Fatalities Belonging to Different Species, by Group; N= 357

Panels show: (a) fatalities by species of avian migrants, (b) fatalities by species of avian residents, (c) fatalities by species of avian winter residents, and (d) fatalities by species of raptors. Groups were created based on knowledge of species typically found on the Project site at different times of the year.

3.3.2 Results of 5-day Repeat Surveys

The first 5-day repeat surveys occurred on 29 October 2012. For the period of 29 October 2012 to 15 August 2013, 45 fatalities were found by repeat searchers. Thirty-six percent of all fatalities found by 5-day repeat searchers were mourning doves (Figure 12).

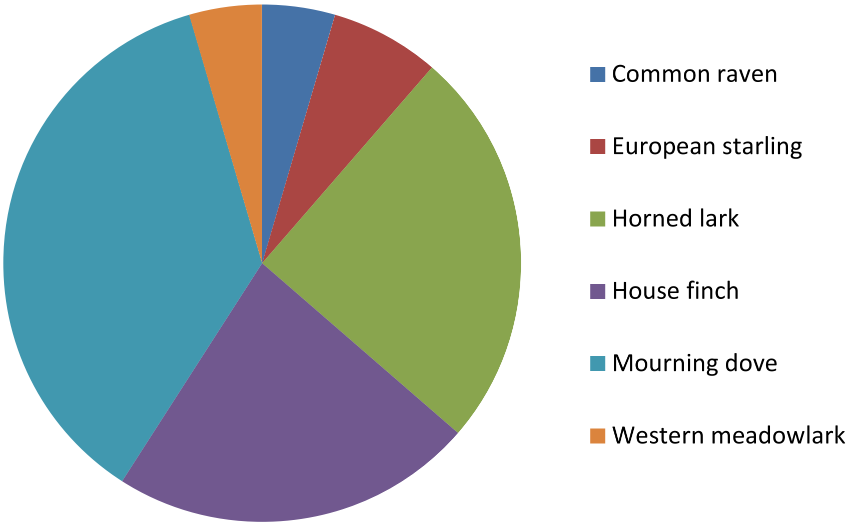

Figure 12. Total Fatalities Found during 5-Day Repeat Surveys, by Species; N= 45

3.3.3 Results of 1-day Repeat Surveys

3.3.3.1 1-Day Repeat Surveys of Weekly Search Areas

One-day (twice monthly) repeat surveys of weekly search areas began in the third quarter of the reporting period (i.e., in March 2013). In total, 16 fatalities were found by 1-day repeat searchers. Of these 16 fatalities, 25% were horned larks (Figure 13).

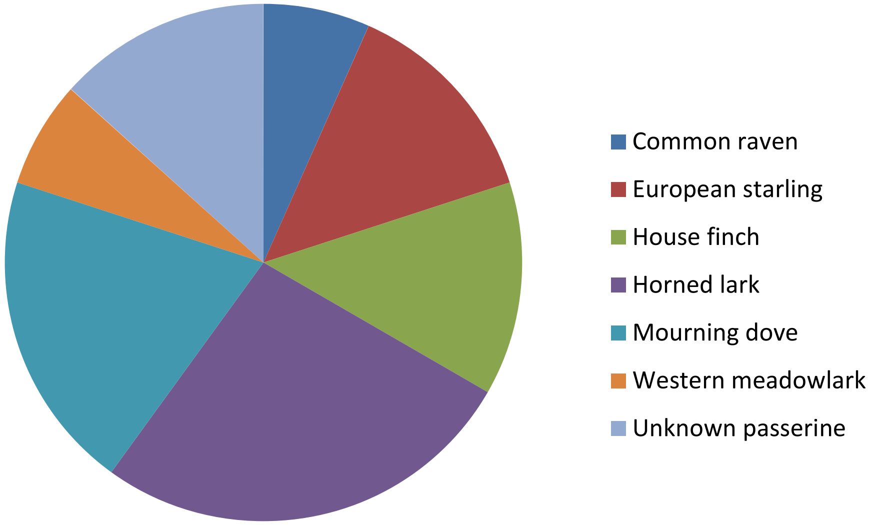

Figure 13. Total Fatalities Found during 1-day Repeat Surveys of Regular Weekly Search Areas, by Species; N= 16

3.3.3.2 1-Day Repeat Surveys of 5-Day Repeat Survey Areas

One-day repeat surveys of 5-day repeat areas also began in the third quarter of the reporting period. Between the third and fourth quarters, only one fatality was found during 1-day repeat surveys of these areas. This fatality was the feather spot of a common raven, found in Array 4.

3.3.4 Electrocutions

Although the cause of death is often difficult to determine, there were four clear cases of electrocution found during the reporting period. An additional two cases of electrocution were found the day before the period began, 15 August 2012. Although outside the official reporting period and excluded from all other analyses, we include mention of these deaths. All six electrocuted animals were ravens, and all electrocutions occurred on overhead lines, rather than in energized arrays. These cases are described in more detail below.

At Tower 7 along the Gen-tie Line, four common ravens were clearly electrocuted in two separate events on August 15 2012 and on 11 December 2012, as evidenced by scorch marks on their feet, and leg scales that were detached and curled. Tower 7 was evaluated and retrofitted during a plant outage on 22 January 2013 to prevent avian electrocutions. Changes to the tower conductor design to prevent electrocution included insulation of exposed conductors in configurations that could potentially create a ground-to-phase connection through a bird. No avian mortalities caused by electrocution related to Tower 7 have been observed since the correcting retrofit.

In April 2013, two ravens were found electrocuted along the MVOH Line. One bird had a clear exit burn through its neck, and singed feathers. The riser poles were temporarily modified to reduce the potential for further electrocutions until long-term remediation could be performed. NRG, SunPower, and Bechtel each consulted with experts on Avian Power Line Interaction Committee (APLIC) guidelines. Based on the consultations, perch diverters, squirrel guards, insulation, and covers were installed, and ground wires were relocated to minimize the potential for ravens or raptors to make contact between two energized phases or an energized phase and the ground at all potential contact points on the riser poles. These improvements were made to all Project MVOH Line riser poles. No further fatalities have occurred as a result of electrocution since these changes were made to the MVOH Line.

3.3.5 Tamarisk Pond

An 80-m section of the Gen-tie Line runs directly over a wetland consisting of a pond lined with saltcedar (*Tamarix ramosissima*). Because a large colony of red-winged blackbirds (*Agelaius phoeniceus*) and other species, such as tricolored blackbirds (*Agelaius tricolor*), a California species of special concern, nest in the wetland during the breeding season, we were unable to search this wetland at times during the reporting period. We stopped searching the pond on 15 March 2013, at the start of the breeding season. Also, because of stark differences in both bird activity and searcher efficiency in this area, we excluded the wetland from fatality estimates. Ten fatalities were found in this area: one long-eared owl, eight horned larks, and one lark sparrow.

3.4 Fatality Estimates from Weekly Searches

For the arrays and control plots, our estimates of the number of fatalities found per tracker unit during the search interval range from 5.68 in Array 2 to 0.95 in Array 8 (Table 11). For Project elements that were linearly searched (i.e., fences and overhead lines), our estimates of fatalities vary from 47 total fatalities along the fence around Arrays 1 and 2 to 446 along the Gen-tie Line (Table 12).

The Gen-tie Line was the only Project element that was searched for a whole year during this reporting period; therefore, this Project element is the only one for which we can accurately estimate seasonal fatality effects for the entire year. Contrary to our initial predictions, the number of small passerine carcasses found along the Gen-tie Line was much greater than the number of large birds and raptors found along the line (Table 13).

Table 11. Overall Fatality Estimates from Weekly Searches and 1-Day Repeat Searches of Nonlinear Areas, Using Wildlife Fatality Estimator, 16 August 2012 to 15 August 2013.

Site	Survey Period (Days)	Number of Fatalities Found in Sample Area	Estimated Number of Fatalities per Tracker Unit	90% Confidence Intervals (No. fatalities per tracker unit)	Estimated Number of Fatalities for Project Element	90% Confidence Intervals (Total no. fatalities)
Array 1	324	41	3.21	2.26, 5.35	212	150, 354
Array 2	261	125	5.68	4.17, 9.10	648	476, 1038
Array 2 Serengeti	63	8	1.02	0.69, 1.74	37	25, 63
Arrays 4 and 5	218	26	2.77	2.03, 4.25	449	329, 689
Array 8	220	11	0.95	0.55, 1.72	258	150, 464
Arrays 1 and 2 control plots	289 and 287	9	2.69	1.54, 5.35	60	34, 118
Arrays 4 and 8 control plots	190 and 192	2	0.73	0.55, 1.12	8	6, 12

Notes: Number of fatalities found in sample area does not include fatalities found during 5-day repeat searches or clearance searches, or carcasses older than the search interval. The size of the array and number of searches conducted vary by array, so results are not directly comparable. Survey Period (days) is the number of days from the onset of surveys at each site until 15 August 2013. Refer to Table 10 for a full list of the number of tracker units per array and dates searched. The numbers of estimated fatalities are rounded up to the nearest whole number. Estimates made based on fewer than five fatalities should be interpreted with caution.

Table 12. Overall Fatality Estimates from Weekly Searches and 1-Day Repeat Searches of Linear Areas, Using Wildlife Fatality Estimator, 16 August 2012 to 15 August 2013

Site	Number of Fatalities Found in Sample Area	Estimated Total Number of Fatalities	90% Confidence Intervals
Array 1–2 fence	11	47	35, 74
Array 4 fence	1	NA	NA
Array 5 fence	0	NA	NA
Array 8 fence	0	NA	NA
Gen-tie Line	83	446	343, 682
MVOH Line	14	71	51, 114

Notes: Number of fatalities found does not include fatalities found during 5-day repeat searches or clearance searches, or carcasses older than the search interval. The length of the line or fence and the number of searches conducted vary by Project element, so results are not directly comparable. The numbers of estimated fatalities are rounded up to the nearest whole number. Refer to Table 1 for full list of dates and survey lengths.

Table 13. Fatality Estimates from the Gen-tie Line by Season and Fatality Class

	Number of Fatalities Found	Estimated Total Number of Fatalities	90% Confidence Intervals
Fatality Class			
Large	21	44	38, 58
Small	69	403	303, 629
Season			
Fall	18	87	68, 128
Winter	17	69	54, 100
Spring	37	214	160, 339
Summer	18	78	60, 119

Note: Numbers of estimated fatalities are rounded up to the nearest whole number.

Finally, although we do not have a full year's worth of data to report for the remainder of the Project elements, both of the overhead lines and Arrays 1, 2, 4, 5, and 8 were all searched in spring and summer, so we were able to compare estimates from these two periods among different Project elements. The estimated number of fatalities per kilometer was much higher for the Gen-tie Line than the MVOH Line in both spring and summer (Table 14). The highest estimated number of fatalities for arrays was 2.65 per tracker unit (Array 2 in spring), and the lowest estimated number of fatalities was 0.11 per tracker unit (Arrays 4 and 5 in summer).

Table 14. Fatality Estimates from the Arrays and Overhead Lines by Season, per Tracker Unit or Kilometer

Project Element	Season[a]	Number of Fatalities Found in Sample Area	Estimated Number of Fatalities (per tracker unit or km)[b]	90% Confidence Intervals (per tracker unit or km)	Estimated Total Number of Fatalities for Project Element	90% Confidence Intervals (Total no. fatalities)
Array 1	Spring	10	0.9	0.46, 1.75	60	31, 116
	Summer	9	0.67	0.32, 1.35	45	21, 89
Array 2	Spring	57	2.65	1.87, 4.37	303	213, 498
	Summer	12	0.69	0.34, 1.38	79	40, 158
Arrays 4 and 5	Spring	6	0.87	0.33, 1.77	141	53, 287
	Summer	1	0.11	0.09, 0.37	18	14, 60
Array 8	Spring	3	0.26	0.08, 0.55	70	23, 150
	Summer	3	0.46	0.17, 1.22	124	48, 329
Array 1 and 2 control plots	Spring	4	0.97	0.27, 2.19	22	7, 49
	Summer	1	0.59	0.4, 2.45	13	9, 54
Array 4 and 8 control plots	Spring	2	0.73	0.55, 1.12	8	6, 12
	Summer	0	0	NA	NA	NA
Gen-tie Line	Spring	37	54	40, 85	214	160, 339
	Summer	18	20	15, 30	78	60, 119
MVOH Line	Spring	9	7	5, 10	41	31, 65
	Summer	5	5	4, 8	30	21, 50

Notes:

[a] Summer estimates may be artificially low because searches were not conducted during July due to maintenance work in the arrays.

[b] Estimates are given per tracker unit for arrays and control plots, and per kilometer for overhead lines.

3.5 Fatality Estimates from 5-day Repeat Surveys

After removing from the analysis all fatalities that had been missed by previous searchers or were cleared on the first day of the 5-day repeat survey, there were 22 fatalities remaining in the repeat-survey fatality analysis (20 in arrays, one along the MVOH Line, and one along the Array 1–2 fence).

Three additional fatalities had been found in control plots during 5-day repeat surveys, but two were found during clearance activities, and the third was judged to be older than the search interval, so fatality estimates could not be calculated for control plots from data collected during the 5-day repeat surveys.

For the arrays, estimates of fatalities ranged from 405 in Array 8 to 1995 in Arrays 4 and 5 (Table 15). Because the 5-day repeat surveys were started during different seasons in different arrays, the estimates shown in Table 15 are not directly comparable.

Table 15. Number of Surveys, Number of Fatalities Found, and Estimates of Total Fatalities per Element, Based on 5-Day Repeat Searches

Project Element	Number of Surveys	Number of Fatalities Found in Sample Area	Estimated Number of Fatalities for Project Element	90% Confidence Interval
Array 1	10	5	489	191, 1005
Array 2	7	6	628	464, 982
Array 2 Serengeti	11	3	336	224, 532
Arrays 4 and 5	7	4	1995	1283, 3420
Array 8	7	2	405	405, 539
Array 1–2 fence	11	1	84	84, 140
MVOH Line	4	1	111	84, 168

Note: Estimates for elements in which fewer than five fatalities were found should be interpreted with caution.

The rate of deposition of fatalities per day per tracker unit varied among arrays, from 0.007 fatalities per day per tracker unit in Array 8 to 0.063 fatalities per day per tracker unit in Arrays 4 and 5 (Table 16).

Table 16. Fatality Deposition Rates for Arrays and Linear Features

Project Element	Fatalities per Day (per tracker unit or per km)[a]	90% Confidence Interval
Array 1	0.026	0.01, 0.053
Array 2	0.041	0.029, 0.064
Array 2 Serengeti	0.028	0.02, 0.046
Array 4 and 5	0.063	0.039, 0.103
Array 8	0.007	0.006, 0.009
Array 1–2 fence	0.052	0.04, 0.073
MVOH Line	0.131	0.088, 0.219

Note:

[a] Fatality estimates are given per tracker unit for arrays, and per kilometer for fences and overhead lines. Estimates for Array 4, 5, and 8 fences are not included because of insufficient sample sizes (i.e. 0 or 1 observed fatalities).

3.6 Error Assessment Results

The geostatistical analysis of the dispersion of avian fatalities in Array 1 and Array 2 separately, as well as in both arrays combined, indicates that the dispersion of fatalities is not significantly different from a random distribution (Table 17). Knowing that fatalities are randomly distributed within arrays at the Project site is important for designing future sampling because there are no observable high concentrations (clumping) of avian fatalities that need to be taken into consideration. Moreover, a random dispersion pattern indicates that the probability of detecting an avian fatality should not change as a function of the amount of area (or number of tracker units) searched.

Table 17. Descriptive Statistics for Avian Fatalities per Tracker Unit and Results of a Point-pattern Analysis for Detecting Spatial Autocorrelation: Moran's I Test for Assessing the Dispersion of Avian Fatalities

Project Element	Number of Tracker Units	Sum	Mean ± SD	Moran's I (I, Z, *P*[1])	Spatial Dispersion
Array 1	66	52	0.79±0.81	-0.12, -0.81, 0.42	Random
Array 2	114	147	1.29±1.45	0.09, 1.14, 0.25	Random
Arrays 1 and 2	180	199	1.11±1.62	0.09, 1.29, 0.19	Random

Notes: SD = standard deviation, I = statistical measure of spatial autocorrelation, Z = number of standard deviations away from the mean

[1] *P* values indicate no significant difference from a clumped distribution.

Figure 9 illustrates the change in variation in fatality estimate as a function of the number of tracker units sampled. The only source of variation in this plot is the difference in number of tracker units sampled (which indicates carcasses occurred with a random dispersion with a mean and standard deviation of 1.11±1.62 fatalities per tracker unit); the plot does not include any variation generated by other processes (e.g., carcass persistence). The resampling analysis suggests that sampling 20% of the total area (represented by "Number of Trackers Sampled" in the figure) is sufficient to provide a reasonably precise estimate of the Project site fatality rate, with sampling equitably spread throughout the site to ensure a spatially representative overall sample. This analysis suggests that sampling 30–35 tracker units within an array would be sufficient to capture an index of avian fatality.

In sum, given the significant random dispersion of avian fatalities derived from the study period, and the resampling analysis of the coefficient of variation as a function of area searched, we consider it acceptable to monitor 20% of the total area of an array, or collective groups of small arrays at the CVSR Project. Additionally, each sample of an array should comprise 30–35 tracker units, so small arrays (e.g., Array 5) should be combined with other small neighboring arrays, so that 20% of a given set comprises at least 30 tracker units.

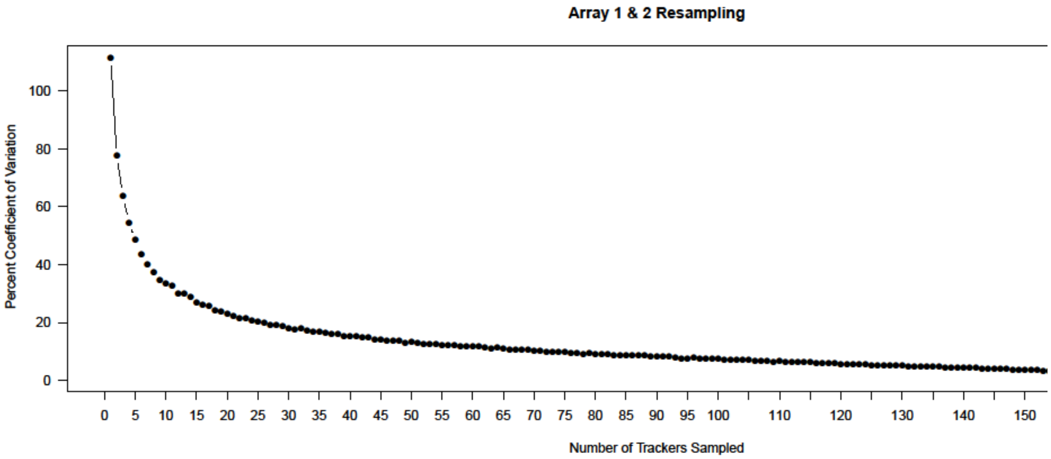

Figure 14. **Coefficient of Variation in Fatality Estimate Attributable to Sampling Variation for All Sample Sizes, Arrays 1 and 2 Combined**

Section 4.0 Discussion

4.1 Carcass-removal Rates

Almost half of placed carcasses were removed completely by scavengers or left insufficient evidence to be documented as a fatality during standardized carcass surveys. More than a third of these carcasses were removed within 7 days of placement, and would not have been detected during weekly fatality searches. The remaining carcasses persisted longer than the search interval, or were scavenged but left sufficient evidence to be considered a fatality by searchers. Only two carcasses left evidence insufficient to be considered a fatality, implying that if a carcass is scavenged in place, its remains will likely be detected during searches. A logical extension of this finding is that the creation of a feather spot when a bird is preyed upon by a raptor or mammalian predator is likely to occur at least as often as the creation of a feather spot during a scavenging event and feather spots created by depredated birds are likely to persist and be detected during searches at rates equal to feather spots created from scavenged carcasses.

The mean time to scavenging was 3.3 days, which is comparable to the mean times identified by carcass-removal studies at other sites. For example, Derby et al. (2007) found an average removal time of 5.1 days for small carcasses, and Smallwood et al. (2010) found an average removal time of 4.45 days for all carcass types. We found that the initial rate of scavenging was very rapid, followed by an exponential decrease; this pattern mirrors the findings of other studies. For example, Ponce et al. (2010) found that 32% of all carcasses were gone by the second day, and 52% of all carcasses were gone within a week. Our study's scavenging times may be somewhat shorter because we avoided scavenger swamping and used cameras. Wagner et al. (1983), Ponce et al. (2010), and Derby et al. (2007) likely overloaded the capacity of local scavengers to effectively dispose of placed carcasses (Smallwood 2010), whereas we placed smaller numbers of carcasses for removal trials. Our use of cameras allowed us to more accurately pinpoint the time of scavenging, whereas other studies (e.g., Derby et al. 2007 and Ponce et al. 2010) were limited by personnel availability; carcasses were often checked only weekly, rather than daily.

Our finding that the majority of small carcasses were removed within 7 days without leaving trace evidence suggests that the majority of small carcasses deposited on the site would be removed with no trace in between our weekly search intervals. Only rarely in our study did small-bodied carcasses leave remains behind after they were scavenged. Also, we found that large carcasses were more likely to leave evidence behind, and are therefore more likely to be detected during routine weekly searches.

The two most common scavengers, ravens and San Joaquin kit foxes, nest or den on the Project site, and coyotes (*Canis latrans*) regularly visit the site. In contrast, turkey vultures (*Cathartes aura*) are rarely seen on site and scavenged only one carcass. Although two other potential scavengers, American badgers (*Taxidea taxus*) and California ground squirrels (*Otospermophilus beecheyi*), occur on site, we did not document them at any of the carcasses that we placed. Likewise, Smallwood et al. (2010) documented red-tailed hawks scavenging carcasses, but we did not record any instances of scavenging by raptors, other than a turkey vulture, or owls in our study.

Although we did not place equal numbers of carcasses during the different seasons, our results do suggest that the time to scavenging was longest in winter and shortest in fall. This is a well-documented trend in carcass-removal trials (e.g., Prosser et al. 2008 and Smallwood et al. 2010). Many of the carcasses placed in winter froze at night, which may have made them less palatable to scavengers, or more difficult to detect by smell. In fall, there is less food available for scavengers because many of the nesting birds have left the area and insects such as grasshoppers are less common. This drop in food availability likely explains the shorter time to scavenging that we observed during this period.

Carcasses placed in the control plots were scavenged more quickly than carcasses placed in the solar arrays or along the Gen-tie Line. Carcasses were likely easier for scavengers to spot visually in the control plots, because there were lower levels of structural and vegetative cover on the control plots than along the Gen-tie Line and in the solar arrays.

Using remote cameras for the carcass-removal trials allowed a more accurate determination of carcass-removal time, reduced personnel time, and helped to document the scavenger species involved in carcass removals. In several instances, ravens removed carcasses within 15 minutes of placement. We could not have documented these quick removal rates without the use of the remote cameras. When cameras malfunctioned or failed to record scavenging, they were still able to narrow the time frame during which the carcass was removed, and so still yielded an advantage over daily or weekly checks by field personnel.

Among the scavenger species documented, ravens, in particular, are known for their high level of intelligence (Emery 2006). It is possible that ravens may have noticed the camera traps, and thus been alerted to the presence of new carcasses. However, Smallwood et al. (2010) explored this possibility by setting out camera traps with decoy carcasses, and found that none of the decoy carcasses were investigated by any scavenger species.

4.2 Searcher-efficiency Rates

Our overall searcher-efficiency rate of 53% is comparable to the results of searcher-efficiency trials conducted at wind energy facilities, where rates have ranged from 32% to 67% (Nicholson et al. 2005; Derby et al. 2007; Leslie et al. 2012; Johnston et al. 2013; Martin et al. 2013).

Although we were not able to make statistical inferences about the influence of season on searcher efficiency, there may be seasonal effects. For example, natural and artificial precipitation events (the solar panels are washed once a year) and the run off of condensed moisture, create patches of grass along the driplines of panels; vegetation changes in color from green to golden-brown and could either blend with or create a sharp contrast with the color of a fatality; and mean daily temperatures (e.g., extreme heat) could affect not only plant growth, but searchers' effectiveness. We observed a significant decrease in our detection rate between winter and spring, likely because in spring the high annual vegetation obscured planted carcasses.

Searcher efficiency in the surveyed rows of the arrays was slightly higher than in unsurveyed rows, as expected given that visibility is often reduced in adjacent tracker rows in the morning and the evening, when the solar panels are tilted the most.

Along the overhead lines, we found that searchers were more efficient at detecting fatality plants in easy visibility areas compared to moderate visibility areas. In many of the arrays and along the MVOH Line, construction-related activities disturbed the ground below the lines and along fence lines; however, vegetation height and density increased with increasing distance from array edges and overhead lines, resulting in reduced fatality detectability. Therefore, the ease of finding fatalities below powerlines and along fences may be magnified by the combined effects of the short distance from the searchers' paths to the fatalities and the relatively lower vegetation.

We found that the opposite was true in the arrays, where detectability was 8% higher in moderate visibility areas than in easy visibility areas. Many searchers focus their attention on the rows of clumped vegetation on either side of a searched row, where vegetation height and density is greater than in the middle of the row. (The vegetation is low to absent in the middle of rows because of continuous foot traffic and conditions that are drier than underneath the panels). This searcher behavior could explain the higher rate of detections in areas characterized as having moderate visibility.

Overall detection rates, explained by type of carcass planted, indicate that carcasses were somewhat easier to find than feather spots as a group, but that the detection of large or small carcasses differed by only 2%, in sharp contrast to a 38% difference in detectability between small and large feather spots. Understandably, feather spots are more detectable when more feathers are scattered over a larger area.

4.3 Weekly Fatality Searches

Causes of death were often difficult or impossible to determine from feather spots and carcasses found in the arrays. In a few cases, carcasses were found with no apparent injuries; in other cases, injuries (e.g., broken necks) indicated that a collision was the cause of death. Determining the cause of death from feather spots was even more difficult. We found feather spots on the ground near panels and on panels themselves. Fatalities may have occurred as a direct or indirect result of the presence of solar panels (e.g., a bird stunned by a collision with a panel can then be more easily predated), or they may indicate direct mammalian or avian predation. Solar panels likely contribute to direct and indirect causes of death for birds, but in many cases, it was not possible to determine cause of death. Because the ratio of feather spots to found carcasses was 20:3 during the reporting period, the inability to partition feather spots associated with collisions and feather spots stemming from predation has important implications regarding inferences that can be drawn from the fatality estimate.

In contrast to the uncertainty regarding causes of death within solar arrays, most fatalities found along the Gen-tie and MVOH Lines were located directly or nearly directly under these lines. This pattern suggests that many of these fatalities were caused by powerline collisions, and that the remains were indicative of scavenging, rather than predation. It is well documented that high-tension powerlines contribute to avian mortality, and especially to the mortality of larger birds such as waterfowl (Brown and Drewien 1995). However, very few large carcasses were detected during fatality searches of the Gen-tie and MVOH Lines. Instead, the majority of fatalities found were passerines, possibly reflecting the greater proportion of passerines that occur on the site. Nevertheless, these results suggest that the avian flight diverters installed on the Gen-tie Line may be successful in preventing collisions with larger birds, but are not effective at diverting smaller birds. Also, Gen-tie Line fatalities included migrant passerines not typically observed on the Project site or expected in the area. It seems likely that most of the migrant passerine fatalities are from nocturnally migrating birds, and the avian flight diverters on the Gen-tie lines appear to be ineffective in deterring these birds at night.

It is difficult to study how the mortality of large and small birds along the overhead lines compares with background mortality rates without having a linear control in the landscape. We know of no studies that control for background mortality rates along a linear corridor without an actual linear structure. Instead, most avian mortality studies of high-tension powerlines typically compare fatality rates of powerlines with or without avian flight-diverting structures (Brown et al. 1995; Janss and Ferrer 1998). Given that more passerine fatalities were documented along the lines than expected, and very few raptor fatalities were documented, a linear control would be useful in understanding how these fatality rates compare with background fatality rates for large and small avian groups in the Project area.

In addition to searching arrays and overhead lines, we conducted fatality searches along perimeter fences. Although these fences may represent a collision hazard for birds (Allen and Ramirez 1990), they also provide artificial hunting-perch habitat for predatory birds, such as loggerhead shrikes and kestrels (*Falco sparverius*) (Bohall-Wood 1987; Sheffield et al. 2001). Both species frequently occur in the arrays, and other studies suggest that they increase in abundance when artificial perches are introduced (Wolff et al. 1999; Yosef and Grubb 1999; Sheffield et al. 2001; Lynn et al. 2006). If perimeter array fences increase hunting opportunities for predatory birds, they may thereby contribute to fatality rates by creating feather spots from predation events along the fence lines and within the adjacent arrays. Flocks of birds, mostly passerines, were commonly seen roosting under the solar panels. Although we do not have data to quantitatively compare this activity in the arrays with roosting in surrounding Conservation Lands, it is plausible that the solar panels attract roosting birds, and thus increase the prey base for predatory birds, which have been documented hunting within the arrays (Refer to Photo 1: a 1-second photo sequence captured on remote camera).

Photo 1. **One-second photo sequence captured on remote camera depicting a red-tailed hawk foraging within a solar array.**

Horned larks and mourning doves commonly roost and nest under the solar panels, and the two species combined represent 63% of the total number of fatalities found within the arrays (Appendix D). When they were flushed, we observed these birds quickly navigating through the panels; in this high-clutter environment, some birds may fly into structural elements of the array. Species that fly in flocks seem to be at a greater risk of collision; it has been posited that birds flying in the rear of flocks are more likely to be unaware of upcoming obstacles (Janss 2000). Additionally, the relatively high densities of these species may provide greater opportunities for avian and mammalian predators to prey on these birds, resulting in feather spots that are recorded as fatalities.

In general, we estimated fatalities to be more abundant in the spring and less in the summer. This pattern is likely associated with the peak avian activity in the spring and the subsequent decline in activity in the summer, both documented through onsite avian point counts (HTH 2013). Because birds were more active on the Project site in spring, predation rates and collision rates are likely to be higher.

Accounting for the spatial organization of avian fatalities is an important aspect of designing surveys and making decisions about future sampling, monitoring, and avoidance and minimization strategies. The spatial organization of avian fatalities may be thought of in terms of the manner in which fatalities are connected with each other in space, and whether they exhibit apparent clumping, uniform or random distribution. This is a key aspect for future design of sampling and monitoring schemes for detecting avian fatalities, because if fatalities are clustered in space, then additional sampling to account for their clumping may be warranted. In this case, significant clumping of fatalities was not found.

4.4 Repeat Surveys

The fatality estimates we calculated from our 5-day and 1-day repeat surveys were all much higher than the estimates obtained from our weekly searches. This is because we extrapolated from the low amount of temporal and spatial coverage in these searches, which can cause high sample bias. The statistical methods we used in the Fatality Estimator are not appropriate for rare events, and caution is recommended when interpreting groups with a sample size lower than five. In all but one area (Array 2), there were fewer than 5 total fatalities found per survey area, included in the 5-day repeat search estimates. The inadequacy of the sample sizes for the repeat surveys (comprising usually only a few tracker units per array) is underscored by the power analysis, which, based on the year of empirical data collected from Arrays 1 and 2, suggests that each sample should comprise 30–35 tracker units (i.e., far more than were actually covered in the past year's repeat surveys).

4.4.1 5-day Repeat Surveys

Because detailed fatality searches have not been conducted previously at a large photovoltaic facility, we did not know at the start of our study whether the fatalities found would be predominately birds or bats. Similarly, there was little basis for projecting what the carcass scavenging rates might be, because scavenging rates often vary widely from location to location, as well as across years and seasons. In situations where carcasses of bats or other animals that are scavenged without leaving a trace occur more commonly, it is advantageous to conduct more intensive daily searches to increase the chances of detecting carcasses. However, after proceeding with the diverse elements of this study for more than a year, it became apparent that avian fatalities, particularly long-lasting feather spots, accounted for the bulk of the findings, and that most small and large carcasses and feather spots persisted for more than 7 days. These facts suggest that daily searches are not necessary at this site to accurately detect and quantify fatalities.

Owing to issues cited in the previous third quarterly report, the protocol for 5-day and regular weekly searchers working in overlapping areas changed at the beginning of June 2013. Therefore, during the fourth quarter, it was possible to determine the short-term permanence (within the 5-day period) of all feather spots and carcasses, whether they were detected during regular weekly searches or not. Although this quarter offered a relatively small sample size (7), data from weekly searches suggested that the relative permanence of feather spots was much greater than that of carcasses. This finding is supported by the overall ratio (20:3) of carcasses to feather spots found in the arrays during regular weekly searches

A general assumption of fatality searches is that searchers detect less than 100% of fatalities, owing to both environmental and individual constraints (e.g., vegetation height, visual obstacles such as support poles for the arrays, and worker fatigue) (Huso 2010). The results of both the 1-day and the 5-day repeat surveys support this premise, because more than half of the finds of repeat searches were missed by weekly searchers. Although the number of fatalities found by weekly searchers but missed by repeat searchers was not examined, we did record cases of weekly searchers finding fatalities that repeat searchers did not find, and it is likely that searcher misses go in both directions. The low rates of consistency between the findings of regular weekly searchers and repeat searchers also suggest that both random differences and differences that vary by individual searcher may affect search outcomes. For example, a taller searcher has a reduced field of vision into adjacent rows compared to a shorter searcher, and is unlikely to be able to fully compensate for this disadvantage, even with conscious efforts to look under the panels. Likewise, there are trade-offs based on where searchers focus their field of vision: if a searcher focuses on tufts of tall grass on the sides of array rows, he or she may overlook fatalities directly underfoot, and vice versa. Estimates of individual searcher efficiencies would provide useful information for model estimation of overall fatality rates. However, identifying individual efficiencies in a field team of our size (around 20 individuals) would require a prohibitively large number of searcher-efficiency trials (more than 1600 per year, excluding the explanatory variables of season and Project element).

Because of the high labor costs and time involved in 5-day repeat searches, the areas searched were very small, covering only 5% of most arrays and 5% of the fences. The small survey area covered and the infrequency of these searches (once a month at each site) resulted in a large sampling bias when extrapolating to entire Project elements. If fatality rates are low or not evenly distributed throughout the site, searching 5% of the area may be insufficient to accurately estimate fatalities, but increasing the search area is nevertheless very expensive and labor intensive. In addition, comparing two different methods for estimating fatalities is difficult when the true number of fatalities in not known, as is the case. Computer simulations may provide a method to test whether 5-day repeat surveys can accurately estimate fatalities on a site. However, the methods for estimating fatalities at wind energy facilities, which we adapted for this study, still represent a tested, reliable, and cost-effective way to estimate fatalities over a large site such as CVSR.

4.4.2 1-day Repeat Surveys

The 1-day repeat surveys were designed to increase understanding of searcher efficiency by providing an independent index of carcasses missed by the weekly searchers. However, 1-day repeat surveys did not provide a full measure of searcher efficiency because the efficiency of the 1-day repeat surveyor was not known. Although the searcher-efficiency trials involved dividing the number of found fatalities by a known number of fatality plants, 1-day repeat surveys counted found fatalities representing some proportion of an unknown total number of fatalities in the area. On this Project site, fatalities rates were not high enough to get an accurate sample from such small survey areas. We found very few fatalities in 1-day repeat surveys. As with the 5-day repeat surveys, the area covered by the 1-day repeat surveys was so small (5% of the array) that it was rare to encounter fatalities. Because our sample size from these searches was too small to make a reliable, independent estimate of searcher efficiency, data from these surveys were incorporated into regular weekly search data. Had fatality rates been higher, we may have been able to use these data in an independent detection probability analysis of searcher efficiency. Using data on the few fatalities actually detected, the results of such an analysis would have been inaccurate.

4.5 Fatality Estimator

This is the first study of its kind to be conducted on a photovoltaic solar project. In a review paper titled "Environmental impacts from the installation and operation of large-scale solar power plants," Turney and Fthenakis predicted that negative impacts on wildlife would occur because of fencing installed in wildlife corridors and changes in food availability and preying strategy, but posited that the number of direct fatalities caused by solar panels was likely to be low compared to other anthropogenic sources of fatalities (Turney and Fthenakis 2011). The only previous study of fatalities at a solar farm took place at a concentrating solar farm in 1983. The primary concern at that facility was singed feathers of birds flying through flux near a central tower generated by heliostats, or panels of reflective mirrors (Wagner et. al 1983). Fatalities in this report were reported over a time period, rather than over a given area, so we were unable to directly compare fatality rates calculated by our study to those previously reported. Likewise, Wagner et al. (1983) did not account for searcher-efficiency rates, and disregarded carcass-removal rates after a preliminary experiment. Failure to account for these issues can severely affect overall fatality estimates.

To give an initial estimate of fatality rates attributable to solar arrays beyond the background fatality rate, we estimated fatality rates for Array 1 using time periods beyond the time period this report covers. We estimated fatalities and confidence intervals for Array 1 based on a full year of data (20 September 2012 to 19 September 2013), and for the control plots for Array 1 and 2 from 15 November 2012 to 14 November 2013. We adjusted the control plot area estimate to cover an area the same size as Array 1 (66 trackers). We then subtracted the lower bound of the confidence interval for the control plot estimate from the Array 1 estimate to obtain an adjusted fatality estimate for Array 1 beyond the background fatality rate.

We estimated that 231 fatalities occurred over a full year in Array 1 (90% confidence intervals: 162, 382) based on 47 fatalities found, and 187 fatalities in the control plots (90% confidence intervals: 107, 367) based on 11 fatalities found. This resulted in an adjusted fatality range 90% confidence interval of 55-275 attributable to the array, or 0.83 to 4.167 fatalities per tracker per year This corresponds to a mean rate of 7.34, or (90% Confidence interval: 3.24 to 16.27 fatalities per MW per year, assuming 0.256MW per tracker).

There are several caveats to keep in mind when interpreting these estimates. As we reanalyze data with full years of surveys for the remaining arrays and control plots these estimates will likely change. Our sample area of control plots in this calculation was based on surveys of 22 tracker sized control plots, which we now know from resampling is a low sample size to calculate fatality rates from, especially for an area as large as the on-site conservation land at the CVSR Project. This is also a conservative adjustment, using only the lower bound of the confidence interval or minimum estimated number of background fatalities.

As we complete full years of surveys for the remaining arrays, this estimate will likely change. However, fatalities per megawatt of installed capacity are a useful metric to compare fatality rates across sites and methods of energy production (Arnett et al. 2008; Smallwood 2013). For example, at regional scales in North America, birds collide with wind turbines at similar rates (National Research Council 2007; Erickson et al. 2008; National Wind Coordinating Collaborative 2010; Smallwood 2013).

In terms of both vegetation and landscape features, the CVSR Project site is fairly homogeneous, particularly in and among arrays, mostly because of the geomorphology of the site but also partly due to the grading and ground disturbance that occurred during construction. Although during the two seasons in which we sampled all arrays, the overall estimates from each array varied by less than one fatality per tracker unit per season, fatality rates for different arrays may vary by season; therefore, a full year of sampling in all arrays is needed before it is known whether or not the number of fatalities is spatially even across arrays.

In contrast to the relatively homogeneous distribution of fatalities in the array areas, the difference between the Gen-tie Line fatalities and the MVOH Line fatalities is striking. The height and size of the Gen-tie and MVOH Lines are considerably different. Much of the linear area along the MVOH Line has been disturbed by construction-related activities, whereas nearly all of the grassland habitat along the Gen-tie Line is intact, and disturbance was limited to the tower pads and access roads to the pads. A natural wetland that provides many avian species with important resources also occurs along the Gen-tie Line. Furthermore, construction of the Gen-tie Line was completed in June 2012, whereas construction close to the MVOH Line was just coming to a close in fall 2013; therefore, noise and ground disturbance likely contributed to overall lower avian activity along the MVOH Line and consequently lower mortality rates.

At all Project elements, we found relatively few owls and diurnal raptors. However, the long-term effects on these birds of collision hazards such as solar arrays are unclear. For species that are K-strategists (i.e., larger animals that have relatively fewer offspring and live long), such as diurnal raptors and owls, even small numbers of fatalities may lead to long-term impacts. Other species that are r-strategists (i.e., smaller animals that have many offspring and are short-lived) may be better able to compensate for lowered population densities by increasing their clutch sizes and fledgling survival rates in response to an increased relative abundance of resources (Drewitt et al. 2008).

4.6 Conclusion and Recommendations

This annual fatality report offers insights into the under-studied effects of large solar photovoltaic installations on avian mortality. In the next annual fatality report, we will be able to report a site-wide estimate of fatalities for all seasons. Likewise, ongoing fatality searches, searcher-efficiency trials, and carcass-removal trials will help to increase the accuracy of our fatality estimates.

Based on our findings to date, we recommend the following:

- **Establish a Linear Control:** To better assess the fatality rates of passerines and raptors across the landscape, fatality searches along a linear control should be conducted, and fatality searches along the Gen-tie Line should continue for another year. Linear controls should be used to evaluate fatality rates along both the Gen-tie and MVOH Lines.

- **Measure Abundance of Passerines as Well as Raptors:** Point counts targeting both raptors and passerines should be conducted in arrays and along linear features, allowing comparisons to data on activity on the Conservation Lands. These counts and comparisons would indicate whether fatality rates are associated with species abundance. The current avian point counts are biased toward raptors and large birds.
- **Examine Ways to Partition Feathers Spots:** Because the ratio of feather spots to found carcasses was 20:3 during the reporting period, the inability to partition feather spots associated with collisions and feather spots stemming from predation has important implications regarding inferences that can be drawn from the fatality estimate. We are examining relationships within the existing data set in an attempt to quantify the relative contribution of predation events to the overall fatality estimates.

Discontinue Repeat Surveys: Given the low fatality rates on the site and the expense and labor involved in repeat surveys, 5-day and 1-day repeat surveys should be discontinued. We recommend focusing efforts on weekly fatality surveys. We recommend that daily searches generally not be conducted to obtain a fatality estimate because they are labor intensive and labor is generally offset by surveying smaller areas. Given the tradeoff between area covered and frequency of searches, it is better to conduct regular weekly searches of a larger proportion of the site. Daily searches would be most useful if they are necessary to answer specific research questions, for example linking fatalities to weather patterns or to test a deterrent method or some other form of mitigation where knowing more precise timing of fatalities is important, but data gathered for answering these questions should not be used to obtain a site-wide estimate.

We recommend avoiding multiple searches of the same area at different time intervals. If surveys are conducted at various search intervals on the same area to answer research questions, we recommend that the different search strategies be designed to avoid interfering with each other. For example, daily searchers would not collect fatalities so they will still be present for weekly searchers to find.

- **Modify Weekly Fatality Search Areas to Improve Sample Size:** We recommend discontinuing 100% searches of Arrays 1 and 2, reducing the coverage of these arrays to 20% based on the results of the subsampling error assessment (power analysis) of the first year of data. All other arrays should also be searched at the 20% level. Further, the smaller arrays close to each other should be combined so that a 20% sample comprises 30–35 tracker units.

- **Conduct Scent Dog Survey Trials:** Scent detection dogs could be used to increase searcher efficiency rates, particularly where grasses and forbs obscure fatalities. If scent dogs prove significantly better during bias trials, we recommend considering the use of scent dogs to conduct fatality searches, most likely in combination with human searchers, at least initially.

Appendix A. Avian Species Used in Searcher-efficiency Trials, September 2012 to September 2013

Species	Carcass Size
American coot (*Fulica americana*)	Large
American crow (*Corvus brachyrhynchos*)	Large
American kestrel (*Falco sparverius*)	Large
Band-tailed pigeon (*Patagioenas fasciata*)	Large
Barn owl (*Tyto alba*)	Large
Black-crowned night heron (*Nycticorax nycticorax*)	Large
Black-headed grosbeak (*Pheucticus melanocephalus*)	Small
Brewer's blackbird (*Euphagus cyanocephalus*)	Small
California towhee (*Melozone crissalis*)	Small
Cedar waxwing (*Bombycilla cedrorum*)	Small
Chestnut-backed chickadee (*Poecile rufescens*)	Small
Common raven (*Corvus corax*)	Large
Common yellowthroat (*Geothylpis trichas*)	Small
Cooper's hawk (*Accipiter cooperii*)	Large
Eurasian collared-dove (*Streptopelia decaocto*)	Large
European starling (*Sturnus vulgaris*)	Small
Greater roadrunner (*Geococcyx californianus*)	Large
Great horned owl (*Bubo virginianus*)	Large
Green heron (*Butorides virescens*)	Large
Horned lark (*Eremophila alpestris*)	Small
House finch (*Carpodacus mexicanus*)	Small
Lesser goldfinch (*Spinus psaltria*)	Small
Long-eared owl (*Asio otus*)	Large
Mourning dove (*Zenaida macroura*)	Large
Rock pigeon (*Columba livia*)	Large
Red-shouldered hawk (*Buteo lineatus*)	Large
Savannah sparrow (*Passerculus sandwichensis*)	Small
Swainson's thrush (*Catharus ustulatus*)	Small
Varied thrush (*Ixoreus naevius*)	Large
Warbling vireo (*Vireo gilvus*)	Small
Western meadowlark (*Sturnella neglecta*)	Small
Western scrub-jay (*Aphelocoma californica*)	Small
White-tailed kite (*Elanus leucurus*)	Large
Yellow-billed magpie (*Pica nuttalli*)	Large
Yellow warbler (*Setophaga petechia*)	Small

Appendix B. Avian Species Used in Carcass-removal Trials

Species	Carcass Size	Number Placed
Acorn woodpecker (*Melanerpes formicivorus*)	Small	1
American coot (*Fulica americana*)	Large	1
American crow (*Corvus brachyrhynchos*)	Large	7
American goldfinch (*Spinus tristis*)	Small	1
American kestrel (*Falco sparverius*)	Large	1
American robin (*Turdus migratorius*)	Large	2
Anna's hummingbird (*Calypte anna*)	Small	1
Band-tailed pigeon (*Patagioenas fasciata*)	Large	2
Barn owl (*Tyto alba*)	Large	4
Black turnstone (*Arenaria melanocephala*)	Large	1
Brewer's blackbird (*Euphagus cyanocephalus*)	Small	2
California gull (*Larus californicus*)	Large	1
California quail (*Callipepla californica*)	Large	1
California towhee (*Melozone crissalis*)	Small	2
Cerulean warbler (*Setophaga cerulean*)	Small	2
Cliff swallow (*Petrochelidon pyrrhonota)*	Small	1
Common raven (*Corvus corax*)	Large	2
Eurasian collared-dove (*Streptopelia decaocto*)	Large	6
European starling (*Sturnus vulgaris*)	Small	2
Great horned owl (*Bubo virginianus*)	Large	6
Greater roadrunner (*Geococcyx californianus*)	Large	1
Hermit thrush (*Catharus guttatus*)	Small	1
Horned grebe (*Podiceps auritus*)	Large	2
Horned lark (*Eremophila alpestris*)	Small	3
House finch (*Haemorhous mexicanus*)	Small	3
House sparrow (*Passer domesticus*)	Small	1
Lesser goldfinch (*Spinus psaltria*)	Small	2
Lincoln's sparrow (*Melospiza lincolnii*)	Small	1
Mourning dove (*Zenaida macroura*)	Large	4
Northern flicker (*Colaptes auratus*)	Large	1
Northern mockingbird (*Mimus polyglottos*)	Small	1
Peregrine falcon (*Falco peregrinus*)	Large	1
Pine siskin (*Spinus pinus*)	Small	1
Red-shouldered hawk (*Buteo lineatus*)	Large	4
Red-tailed hawk (*Buteo jamaicensis)*	Large	8
Red-winged blackbird (*Agelaius phoeniceus*)	Small	1
Rock dove/pigeon (*Columba livia*)	Large	4
Ruby-crowned kinglet (*Regulus calendulai*)	Small	1
Sharp-shinned hawk (*Accipiter striatus*)	Large	1

Species	Carcass Size	Number Placed
Western meadowlark (*Sturnella neglecta*)	Medium	1
Western screech-owl (*Megascops kennicottii*)	Medium	1
Western scrub-jay (*Aphelocoma californica*)	Medium	4
White-crowned sparrow (*Zonotrichia leucophrys*)	Small	2
White-tailed kite (*Elanus leucurus*)	Large	2
Yellow-rumped warbler (*Setophaga coronata*)	Small	2

Appendix C. Weekly Fatality Search Results: 16 August 2012 to 15 August 2013

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1	9/27/2012	Mourning dove	11S	233981	3915723	Feather spot.
Array 1	9/27/2012	Mourning dove	11S	233987	3915548	Feather spot. Suspected roosting/preening site.
Array 1	9/27/2012	Common raven	11S	233705	3915535	Feather spot.
Array 1	9/27/2012	Common raven	11S	234004	3915528	Feather spot.
Array 1	10/4/2012	Mourning dove	11S	233512	3915482	Feather spot. Suspected roosting/preening site.

Array 1	10/18/2012	Burrowing owl	11S	233886	3915595	Feather spot.
Array 1	10/18/2012	Horned lark	11S	233579	3915738	Feather spot.
Array 1	10/18/2012	Horned lark	11S	233928	3915518	Feather spot.
Array 1	10/18/2012	Burrowing owl	11S	234000	3915471	Feather spot.
Array 1	10/25/2012	Horned lark	11S	233714	3915431	Feather spot.
Array 1	11/1/2012	Horned lark	11S	233442	3915776	Partial carcass with wings, legs, and bill. Bill impaled on tumbleweed. Cause of death possible predation by loggerhead shrike (LOSH).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1	11/1/2012	Horned lark	11S	234110	3915654	Feather spot.
Array 1	11/8/2012	Horned lark	11S	234103	3915641	Feather spot.
Array 1	11/8/2012	Mourning dove	11S	233950	3915518	Feather spot. Suspected roosting/preening site.
Array 1	11/8/2012	Western meadowlark	11S	233822	3915671	Breast feathers. Some skin attached.
Array 1	11/8/2012	Medium-sized bird	11S	233426	3915528	Medium-sized bird based on articulated knee or elbow and fibula/tibia.
Array 1	11/8/2012	Mourning dove	11S	233807	3915533	Feather spot (body feathers). Suspected roosting/preening site.
Array 1	11/8/2012	Short-eared owl	11S	233815	3915688	Feather spot. Feathers on panel. Cause of death possible panel strike.
Array 1	11/8/2012	Short-eared owl	11S	233891	3915349	Feather spot. Feathers, possible organs, whitewash, spot with dirt absent on panel. Cause of death possible panel strike.
Array 1	12/20/2012	Mourning dove	11S	233412	3915438	Feather spot (>50 body feathers). Feathers scattered over 2x2-m area.
Array 1	1/10/2013	House finch	11S	234021	3915462	Head impaled on tumbleweed. Cause of death possible predation by LOSH.
Array 1	1/10/2013	Horned lark	11S	234056	3915775	Feather spot (several primaries and body feathers). Smudge marks and four body feathers stuck to the bottom right corner of panel. Feathers found at the array edge. Cause of death likely a panel strike.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1	1/17/2013	Horned lark	11S	233952	3915772	Feather spot.
Array 1	1/17/2013	Western meadowlark	11S	233462	3915602	Feather spot (primaries, body, and contour feathers). Spread across 2x2-m area, likely wind-blown.
Array 1	1/31/2013	Horned lark	11S	233446	3915562	Feather spot (downy feathers).
Array 1	1/31/2013	House finch	11S	233740	3915310	Feather spot. Flesh on some feather tips.
Array 1	1/31/2013	Western meadowlark	11S	233930	3915672	Feather spot.
Array 1	1/31/2013	Mourning dove	11S	234119	3915660	Feather spot (13 body feathers). Suspected roosting/preening site.
Array 1	2/14/2013	Western meadowlark	11S	231009	3915719	Feather spot.
Array 1	3/21/2013	Horned lark	11S	234249	3915566	Feather spot (≥25 back and breast feathers). Several feathers found on the bare ground under the panels.
Array 1	3/28/2013	Horned lark	11S	234151	3915458	Feather spot. Near acoustic station near Array 1.
Array 1	4/18/2013	Horned lark	11S	234062	3915720	Feather spot (two secondaries with coverts attached, one secondary, and more than ten body feathers).
Array 1	5/9/2013	House finch	11S	234155	3915577	Feather spot (four primaries, ≥20 contour feathers).
Array 1	5/9/2013	Horned lark	11S	233866	3915476	Feather spot (~15 breast feathers in a clump).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1	5/16/2013	Horned lark	11S	233445	3915794	Feather spot (≥15 flight feathers and ≥50 body feathers).
Array 1	5/23/2013	House finch	11S	233794	3915504	Feather spot (~40 breast feathers).
Array 1	5/23/2013	Mourning dove	11S	233689	3915385	Feather spot (approximately ten body feathers tightly clumped).
Array 1	5/23/2013	Horned lark	11S	234007	3915780	Feather spot (seven tail feathers, ten primaries attached by tissue, ≥20 contour feathers, and four secondaries).
Array 1	5/30/2013	Horned lark	11S	233732	3915516	Feather spot. Wing parts and contour feathers. Nest with eggs ~30 cm away. Bird may have been predated.
Array 1	6/13/2013	American kestrel	11S	233506	3915434	Feather spot (five feathers, including three primaries).
Array 1	6/20/2013	American kestrel	11S	234249	3915575	Feather spot (one secondary, five wing coverts, and 15 breast feathers).
Array 1	7/18/2013	Mourning dove	11S	233427	3915713	Feather spot (~15 body feathers tightly clustered).
Array 1	7/18/2013	House finch	11S	233949	3915584	Feather spot (~15 body feathers).
Array 1	7/25/2013	Mourning dove	11S	233858	3915327	Feather spot (~25 contour feathers and coverts).
Array 1	7/25/2013	Great horned owl	11S	233865	3915329	Feather spot (11 contour feathers). Feathers worn and older than search interval.
Array 1	8/1/2013	House finch	11S	233704	3915471	Feather spot (~15 feathers of a wing). Feathers barely attached.
Array 1	8/1/2013	Common raven	11S	233570	3915547	Feather spot (~20 breast feathers attached in a clump to dried flesh).
Array 1	8/1/2013	Horned lark	11S	233908	3915420	Feather spot (12 secondaries and contour feathers). Feathers worn and older than search interval.
Array 1	8/8/2013	Mourning dove	11S	233431	3915425	Feather spot (17 contour feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1	8/8/2013	Common raven	11S	233602	3915623	Feather spot (ten primaries, 15 body feathers, and small amount of flesh dried to feathers).
Array 1	8/15/2013	Common raven	11S	233658	3915633	Partial carcass (wing).
Array 1 control plot	11/15/2012	Blackbird sp.	11S	234421	3915557	Feather spot.
Array 1 control plot	4/18/2013	Horned lark	11S	234835	3914331	Feather spot (two secondaries and three tail feathers).
Array 1 control plot	5/23/2013	Common raven	11S	234394	3915663	Feather spot (~20 contour feathers).
Array 1–2 fence	2/19/2013	Horned lark	11S	233393	3915496	Feather spot (≥15 body, one primary, and three secondary feathers).
Array 1–2 fence	3/5/2013	Mourning dove	11S	233616	3914432	Feather spot (≥20 body and breast feathers). Could be preening spot, but feathers were scattered in 1-m radius. Some feathers stuck together. Found 30 m north of fence point 17.
Array 1–2 fence	3/12/2013	Mourning dove	11S	233623	3914542	Feather spot (~50 breast feathers). Approx. 0.5 m east of fence.
Array 1–2 fence	5/7/2013	Unknown small bird	11S	234252	3914464	Feather spot (~20 body feathers, dark grey in color). Clearly rained upon.
Array 2 control plot	12/4/2012	Horned lark	11S	234801	3915162	Feather spot.
Array 2 control plot	2/5/2013	Tree swallow	11S	234303	3913572	Feather spot.
Array 2 control plot	2/5/2013	House finch	11S	234299	3913638	Whole carcass. No obvious injuries or signs of ill health.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 control plot	4/16/2013	Common raven	11S	233760	3914054	Feather spot (mixture of ~25 secondaries and contour feathers). Feathers scattered across 5 m.
Array 2 control plot	5/21/2013	Horned lark	11S	234756	3915202	Feather spot (15 flight feathers and ≥50 body feathers).
Array 2 control plot	7/23/2013	Horned lark	11S	233650	3914101	Feather spot (one tail feather and 14 contour feathers).
Array 2 North	12/4/2012	Western meadowlark	11S	234107	3915294	Feather spot. Wing (with some flesh) under panel at edge of tracker. Feather spot 4.6 m east, on top of panel (≥10 feathers stuck on panel with large smear marks).
Array 2 North	12/11/2012	Mourning dove	11S	234417	3915072	Feather spot. Body feathers and mourning dove (MODO) fecal droppings present. Suspected roosting/preening site.
Array 2 North	12/11/2012	Mourning dove	11S	233923	3915097	Feather spot. Body feathers and MODO fecal droppings present. Suspected roosting/preening site.
Array 2 North	12/11/2012	Horned lark	11S	234354	3915162	Feather spot.
Array 2 North	1/8/2013	Horned lark	11S	234492	3915122	Feather spot.
Array 2 North	1/8/2013	Horned lark	11S	234281	3915343	Feather spot (ten or more primaries and >50 downy feathers).
Array 2 North	1/8/2013	Horned lark	11S	234349	3915216	Whole carcass. Bird apparently died just prior to survey. Very good condition and weight. Possible head trauma. Seizure before death. No definitive evidence of panel strike. Cause of death potential panel strike.
Array 2 North	1/8/2013	Unknown small bird	11S	234013	3914931	Feather spot.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	1/8/2013	Mourning dove	11S	233775	3915006	Feather spot. Two feathers have blood on the ends.
Array 2 North	1/8/2013	Mourning dove	11S	233998	3915109	Feather spot.
Array 2 North	1/8/2013	Western meadowlark	11S	234474	3915002	Feather spot (clump of feathers).
Array 2 North	1/8/2013	California quail	11S	234458	3915015	Feather spot (clump of breast feathers).
Array 2 North	1/8/2013	American pipit	11S	233947	3915001	Whole carcass. No evidence of panel strike.
Array 2 North	1/15/2013	Mourning dove	11S	234116	3915029	Feather spot (primaries, secondaries, and body feathers).
Array 2 North	1/15/2013	Mourning dove	11S	234116	3915045	Feather spot (several downy and flight feathers). Found in same row as MODO feather spot from same day. Probably same fatality.
Array 2 North	1/15/2013	Common raven	11S	234369	3915286	Feather spot (contour feathers).
Array 2 North	1/15/2013	Western meadowlark	11S	234254	3915320	Feather spot (body feathers in small clump).
Array 2 North	1/15/2013	Common raven	11S	234384	3915309	Feather spot (body feathers).
Array 2 North	1/22/2013	Common raven	11S	234377	3915298	Feather spot (contour feathers). Potentially remnants from a previously collected common raven (CORA) fatality (1/15/13).
Array 2 North	1/22/2013	Mourning dove	11S	233835	3914945	Feather spot (clump of body feathers).
Array 2 North	1/22/2013	Mourning dove	11S	233902	3914945	Feather spot (downy feathers). Suspected preening site.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	1/22/2013	Mourning dove	11S	234359	3915322	Feather spot. Suspected preening site above cable tray.
Array 2 North	1/22/2013	Mourning dove	11S	234119	3915035	Feather spot (scattered feathers and one clump).
Array 2 North	1/22/2013	Horned lark	11S	234173	3915114	Feather spot.
Array 2 North	1/22/2013	California quail	11S	234393	3914986	Feather spot (clump of feathers).
Array 2 North	1/29/2013	Mourning dove	11S	233891	3914945	Feather spot (mostly breast feathers). Not under panel like most MODO preening areas.
Array 2 North	1/29/2013	Mourning dove	11S	234015	3914931	Feather spot (one clump of body feathers).
Array 2 North	1/29/2013	Mourning dove	11S	234365	3915193	Feather spot.
Array 2 North	1/29/2013	Mourning dove	11S	234367	3915164	Feather spot. Body feathers spread down row.
Array 2 North	2/5/2013	House finch	11S	234212	3915338	Whole carcass (broken neck). Cause of death potential panel strike.
Array 2 North	2/5/2013	Mourning dove	11S	233991	3914940	Feather spot. Skin attached to feathers.
Array 2 North	2/12/2013	Mourning dove	11S	234182	3915342	Feather spot (body and flight feathers). Some feathers with dried flesh attached at shaft base. Five body feathers stuck to solar panel, but no evidence of strike. Spread across entire tracker unit row.
Array 2 North	2/12/2013	Unknown small bird	11S	234198	3915347	Skeletal remains of wing and keel bones. Bones picked clean. Dried muscle fibers still attached but

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
						stringy.
Array 2 North	2/12/2013	Western meadowlark	11S	234409	3915384	Feather spot (~20 contour feathers).
Array 2 North	2/12/2013	House finch	11S	234464	3915452	Feather spot. Wing feather clumps. A few body and flight feathers on panel, but no evidence of panel strike. Many body feathers on ground under panel on outside face of tracker.
Array 2 North	2/12/2013	Mourning dove	11S	234386	3915162	Feather spot (~20 scattered downy feathers).
Array 2 North	2/12/2013	Mourning dove	11S	234386	3915157	Feather spot (two downy feathers on panel, two flight feathers on ground). No evidence of panel strike.
Array 2 North	2/12/2013	Mourning dove	11S	234260	3915252	Feather spot (>100 body and >10 flight feathers). Approximately 11 body feathers on panel, but no evidence of panel strike.
Array 2 North	2/19/2013	House finch	11S	233861	3914831	Feather spot (a few primaries and a few body feathers).
Array 2 North	2/19/2013	Mourning dove	11S	234396	3915436	Feather spot (≥50 feathers—ten or more secondaries and tertials and ≥40 body feathers). Feathers found stuck on panel. Possible panel strike or prey possibly eaten on panel.
Array 2 North	2/19/2013	Mourning dove	11S	234115	3915291	Feather spot (seven primaries with skin attached). Some feathers found stuck to panel. Possible panel strike or prey possibly eaten on panel.
Array 2 North	2/19/2013	Mourning dove	11S	234114	3915292	Feather spot (four or more secondaries, ≥15 body feathers, one tail feather, and one larger body feather). Absence of droppings and wide scatter of feathers indicate fatality and not preening station.

Area	**Date**	**Species**	**UTM**	**Easting**	**Northing**	**Observation Details[1]**
Array 2 North	2/19/2013	House finch	11S	234484	3915068	Feather spot (ten primaries and ≥50 body feathers). All feathers there—plucked.
Array 2 North	2/19/2013	Horned lark	11S	234442	3915295	Feather spot (≥15 body feathers and five or more primaries). Found directly under a panel.
Array 2 North	2/19/2013	House finch	11S	234164	3915141	Feather spot (≥30 body feathers).
Array 2 North	2/19/2013	House finch	11S	234261	3915153	Feather spot (ten primaries and ≥30 body feathers).
Array 2 North	2/26/2013	Western meadowlark	11S	234337	3915123	Feather spot (≥15 body feathers). All contour feathers. Isolated spot (not scattered).
Array 2 North	3/5/2013	Horned lark	11S	233901	3915118	Feather spot (five or more secondaries and ≥15 body feathers).
Array 2 North	3/5/2013	Horned lark	11S	234406	3915204	Whole carcass. Eyes gone but still fresh. Body warm but could be from intense sun. No visible signs of injury.
Array 2 North	3/5/2013	Horned lark	11S	234348	3915190	Feather spot (≥15 body feathers). White tips on body feathers.
Array 2 North	3/5/2013	Mourning dove	11S	234341	3915343	Feather spot (two flight feathers).
Array 2 North	3/12/2013	Mourning dove	11S	234227	3915000	Feather spot (≥50 body feathers and five or more flight feathers—mostly secondaries). Grey/white feathers. Spread over four rows. Some clumped feathers. Not a preening site.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	3/12/2013	Western meadowlark	11S	234250	3915070	Feather spot (one wing of ~20 primaries, five or more coverts, and yellow breast feathers).
Array 2 North	3/19/2013	House finch	11S	234341	3915005	Feather spot. Wings, foot, and feathers present (two wing partials; ≥20 primaries, secondaries, and coverts; and ≥50 body feathers). Bright red breast feathers present.
Array 2 North	3/26/2013	Horned lark	11S	234343	3915283	Whole carcass. Ants found in head and eye sockets. Found about 1 m from another horned lark (HOLA) fatality on same day. No signs of injury.
Array 2 North	3/26/2013	Horned lark	11S	234342	3915282	Feather spot. (partial wing, ten or more primaries and secondaries, five or more coverts, and ≥20 body feathers). Found about 1 m south of full HOLA carcass.
Array 2 North	4/2/2013	Horned lark	11S	234269	3914950	Feather spot. One clump of feathers on the cable tray (five primaries, six secondaries, two coverts, and one tail feather).
Array 2 North	4/2/2013	Horned lark	11S	234234	3915032	Feather spot. Clump of feathers (≥30 body feathers).
Array 2 North	4/2/2013	Horned lark	11S	234232	3915019	Feather spot (four primaries, eight secondaries, five tertials, and 12 contour feathers).
Array 2 North	4/16/2013	Horned lark	11S	234267	3915289	Whole carcass. No signs of injury.
Array 2 North	4/23/2013	Mourning dove	11S	234517	3915331	Feather spot (~15 primaries, 35 secondaries, ten tail feathers, 20 mantle feathers, and several hundred body feathers).
Array 2 North	4/30/2013	Mourning dove	11S	234268	3915260	Feather spot (one flight feather, ≥10 body feathers, and five body feathers in a clump).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	4/30/2013	Horned lark	11S	234215	3915114	Feather spot. Most feathers, including more than ten remiges, more than five retrices, and >75 contour feathers.
Array 2 North	4/30/2013	Horned lark	11S	234396	3914943	Feather spot (15 flight feathers, six tail feathers and 15 body feathers). Shafts of feathers broken. Possible juvenile, judging by sheaths. Probably not molting at this time of year. Feathers stuck to panel and cable tray. Possible panel strike or prey possibly eaten on panel.
Array 2 North	5/7/2013	Common raven	11S	234388	3915306	Feather spot (~30 body feathers). Some clumps of body feathers.
Array 2 North	5/7/2013	Horned lark	11S	234094	3915266	Feather spot (three tail feathers).
Array 2 North	5/14/2013	Horned lark	11S	234086	3915503	Whole carcass. Urea present on bird—most likely died minutes before discovered. Broken neck. Possible panel strike.
Array 2 North	5/21/2013	Horned lark	11S	234025	3915288	Feather spot (15 flight and five tail feathers). Found outside of tracker, off the side of the access road.
Array 2 North	5/28/2013	Horned lark	11S	234378	3915245	Whole carcass. Bird appeared emaciated, had excrement on cloaca.
Array 2 North	5/28/2013	Horned lark	11S	234072	3915037	Feather spot (one primary feather, ~40 body feathers, and five coverts).
Array 2 North	5/28/2013	Horned lark	11S	234343	3915250	Feather spot (six contour feathers and one tail feather). Two predated HOLA nests within 3–5 m of feathers.
Array 2 North	5/28/2013	Horned lark	11S	234073	3915038	Feather spot (~15 flight feathers, including some wing feathers still attached, and five body feathers).
Array 2 North	5/28/2013	House finch	11S	234020	3915176	Feather spot (feathers, wing, leg, and feathers with dried flesh).
Array 2 North	6/4/2013	House finch	11S	234338	3914975	Feather spot (11 body feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	6/4/2013	Common raven	11S	234338	3914976	Feather spot (~15 body feathers on road, close to panels).
Array 2 North	6/4/2013	House finch	11S	234315	3915314	Feather spot (seven flight feathers, ten body feathers, and five attached wing feathers).
Array 2 North	6/11/2013	Horned lark	11S	234520	3915047	Feather spot (two primaries and one contour feather). May not be a fatality because HOLAs were molting heavily at this time.
Array 2 North	6/11/2013	House finch	11S	234376	3915093	Feather spot (20 breast feathers, some clumped). Some feathers appeared to be plucked.
Array 2 North	6/11/2013	House finch	11S	234056	3915253	Feather spot (parts of wing, body feathers, and bone fragments).
Array 2 North	6/18/2013	Horned lark	11S	234193	3915167	Feather spot (partial wing and body feathers).
Array 2 North	6/25/2013	Mourning dove	11S	234211	3914933	Feather spot (two clumps, each with approximately eight contour feathers). Found on outside end of the tracker.
Array 2 North	6/25/2013	Horned lark	11S	234448	3915393	Feather spot (~15 body feathers, one contour feather, and one primary).
Array 2 North	7/23/2013	Horned lark	11S	233886	3914829	Feather spot (~50 body feathers and 20 flight feathers).
Array 2 North	7/30/2013	Mourning dove	11S	234289	3915258	Feather spot (several contour feathers).
Array 2 Serengeti	10/16/2012	Horned lark	11S	234520	3915036	Feather spot. Blood on some feathers.
Array 2 Serengeti	10/23/2012	Mourning dove	11S	234310	3914949	Feather spot (body feathers). Suspected roosting/preening site.
Array 2 Serengeti	10/23/2012	Mourning dove	11S	234344	3914998	Feather spot (body feathers). Suspected roosting/preening site.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 Serengeti	10/23/2012	Savannah sparrow	11S	234363	3915303	Whole carcass. No obvious injuries.
Array 2 Serengeti	10/30/2012	Mourning dove	11S	234231	3915068	Feather spot.
Array 2 Serengeti	10/30/2012	Mourning dove	11S	234526	3914949	Feather spot.
Array 2 Serengeti	11/13/2012	Western meadowlark	11S	234426	3915134	Feather spot.
Array 2 Serengeti	11/13/2012	Mourning dove	11S	234335	3915010	Feather spot.
Array 2 South	12/4/2012	Mourning dove	11S	233991	3914554	Feather spot (several flight feathers).
Array 2 South	12/4/2012	House finch	11S	234257	3914587	Decapitated carcass.
Array 2 South	12/4/2012	Mourning dove	11S	233680	3914437	Feather spot (≥20 body downy feathers and two flight feathers). Many MODO fecal droppings scattered in area. Suspected preening site.
Array 2 South	12/4/2012	Mourning dove	11S	233652	3914448	Feather spot (two feathers, possibly secondaries). Found at outer edge of tracker.
Array 2 South	12/4/2012	Unknown medium-sized bird	11S	233793	3914462	Feather spot (three feathers, including two primaries). Possible rock dove.
Array 2 South	12/11/2012	Western meadowlark	11S	233834	3914500	Feather spot (approximately ten secondaries).
Array 2 South	12/11/2012	Mourning dove	11S	233700	3914515	Feather spot (numerous downy feathers). Suspected preening site.
Array 2 South	12/18/2012	Mourning dove	11S	234132	3914957	Feather spot. In middle of row.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	1/8/2013	Mourning dove	11S	234116	3914561	Feather spot. Clump of feathers stuck to panel. Possible panel strike.
Array 2 South	1/8/2013	Mourning dove	11S	233790	3914470	Feather spot.
Array 2 South	1/8/2013	House finch	11S	234000	3914568	Feather spot. Carcass appears to have been plucked close to impact site. Impact smudge on the panel. Cause of death likely panel strike.
Array 2 South	1/8/2013	House finch	11S	234071	3914567	Feather spot.
Array 2 South	1/8/2013	Mourning dove	11S	233667	3914553	Feather spot (contour and flight feathers).
Array 2 South	1/8/2013	Mourning dove	11S	233888	3914516	Feather spot (approximately ten flight feathers).
Array 2 South	1/8/2013	Mourning dove	11S	233665	3914526	Feather spot (flight, body, and tail feathers). Spot widely scattered over two rows of panels.
Array 2 South	1/15/2013	Mourning dove	11S	234131	3914798	Feather spot (seven feathers: primaries, tail, and body feathers). Some primaries were a little muddy but it had not rained in the previous 24 hours.
Array 2 South	1/15/2013	House finch	11S	234345	3914896	Whole carcass. Odd growth above bill, possible avian pox. No apparent injury. Body still warm and limp, eyes not visible.
Array 2 South	1/15/2013	Mourning dove	11S	233664	3914388	Feather spot. Dried blood on ground. Many MODO roost here. Probably predated while roosting.
Array 2 South	1/22/2013	Mourning dove	11S	233669	3914469	Feather spot. Many (20–30) body feathers scattered throughout tracker, but remained clumped.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	1/22/2013	Mourning dove	11S	233642	3914421	Feather spot (four primaries and 20–30 body feathers).
Array 2 South	1/22/2013	House finch	11S	233654	3914575	Whole carcass. Ants on carcass. No broken vertebrae or broken wings found.
Array 2 South	1/22/2013	Mourning dove	11S	233849	3914553	Feather spot. Suspected roosting site.
Array 2 South	1/22/2013	Western meadowlark	11S	233683	3914427	Feather spot (>100 flight, body, and tail feathers). San Joaquin kit fox (SJKF) scat found on some feathers.
Array 2 South	1/22/2013	House finch	11S	234047	3914606	Partial carcass. Two wings, lower body, and feet found under cable tray and panel.
Array 2 South	1/22/2013	Mourning dove	11S	233654	3914575	Feather spot. Several distinct clumps of feathers.
Array 2 South	1/29/2013	Mourning dove	11S	234303	3914603	Feather spot (two flight feathers and spiral of breast feathers).
Array 2 South	1/29/2013	Mourning dove	11S	234022	3914568	Feather spot.
Array 2 South	2/5/2013	Western meadowlark	11S	233658	3914665	Feather spot. Single body feather and smudge marks on the lower left edge of panel. Large feather spot (body and flight feathers) scattered across tracker row. Some clumps of feathers with dried blood. Cause of death likely a panel strike.
Array 2 South	2/5/2013	House finch	11S	234200	3914856	Partial carcass and large feather spot (rump, two legs, and flight and body feathers). Found between trackers along road. Top portion of bill with orange tuft of feathers present. Breast feathers tinged with orange/red.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	2/12/2013	Mourning dove	11S	233891	3914457	Feather spot (15–20 downy and secondary feathers). No evidence of panel strike.
Array 2 South	2/19/2013	House finch	11S	234105	3914580	Feather spot (five or more primaries, a few secondaries, and ≥30 body feathers). At edge of tracker.
Array 2 South	3/5/2013	Horned lark	11S	234030	3914669	Whole carcass. Bill appears broken. Possible panel strike.
Array 2 South	3/5/2013	House finch	11S	234418	3914852	Feather spot (≥50 body feathers and ten flight feathers—mostly secondaries).
Array 2 South	3/19/2013	Mourning dove	11S	233662	3914435	Feather spot. Two primary feathers found under panel in area of abundant preening activity (fecal matter). Suspected preening site.
Array 2 South	4/2/2013	House finch	11S	234253	3914760	Feather spot (clump of >36 breast feathers, six primaries, and beak). Might have been plucked by avian predator.
Array 2 South	4/2/2013	Mourning dove	11S	233674	3914433	Feather spot (one secondary and 12 contour feathers). Suspected preening site.
Array 2 South	4/23/2013	Horned lark	11S	234030	3914728	Feather spot (~20 body feathers). Possible that more feathers blew away with high wind.
Array 2 South	4/23/2013	Mourning dove	11S	234214	3914706	Feather spot (20 contour feathers).
Array 2 South	4/30/2013	Horned lark	11S	233841	3914512	Feather spot (clump of ten body feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	4/30/2013	Brewer's blackbird	11S	234250	3914496	Feather spot (tip of left wing with flight feathers, coverts and alula, clump of tail feathers, body feathers with some skin, and one leg). More feathers two rows over (body feathers, flight feathers, and leg).
Array 2 South	4/30/2013	Mourning dove	11S	234465	3914864	Feather spot (≥15 body feathers in a few clumps with skin and dried intestine).
Array 2 South	4/30/2013	Common raven	11S	234104	3914491	Feather spot (~15 contour feathers).
Array 2 South	5/14/2013	House finch	11S	234310	3914591	Feather spot (one wing with flight feathers and coverts attached).
Array 2 South	5/14/2013	Unknown	11S	233830	3914497	Intestines of an unknown small animal.
Array 2 South	5/21/2013	Mourning dove	11S	234210	3914543	Feather spot (~20 feathers; three clumps with skin).
Array 2 South	5/21/2013	Horned lark	11S	234031	3914746	Feather spot (approximately six primaries and 35 body feathers).
Array 2 South	7/23/2013	Mourning dove	11S	234421	3914889	Feather spot (25 flight feathers).
Array 2 South	7/23/2013	Horned lark	11S	234439	3914890	Feather spot (five flight feathers).
Array 2 South	7/23/2013	Horned lark	11S	234196	3914623	Feather spot (two tail feathers and 15 body feathers).
Array 2 South	7/30/2013	Horned lark	11S	233649	3914409	Feather spot (~15 contour feathers).
Array 2 South	7/30/2013	Horned lark	11S	234366	3914575	Feather spot (three primaries, three tail feathers, two secondaries, two coverts, and ~35 contour feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	8/6/2013	House finch	11S	233972	3914601	Feather spot (~20 feathers, mostly primaries, and a few body feathers).
Array 2 South	8/13/2013	Horned lark	11S	234360	3914545	Feather spot (five flight feathers and ≥15 body feathers).
Array 4	1/9/2013	Mourning dove	11S	235596	3913032	Feather spot. Feathers in bunches, stuck together in clumps. Contour and wing feathers present, but no primaries or tail feathers.
Array 4	1/9/2013	Mourning dove	11S	235598	3913140	Feather spot. Contour and tail feathers only—no flight feathers present.
Array 4	1/16/2013	Mourning dove	11S	235591	3913465	Feather spot (≥100 body feathers). Feathers mainly in one central area, but some up to 4 m away.
Array 4	1/16/2013	House finch	11S	235672	3913330	Feather spot (14 flight feathers and numerous body feathers) and mandible.
Array 4	1/16/2013	Mourning dove	11S	235679	3913408	Feather spot. Feathers scattered. A second group of feathers, likely from the same bird but collected in a separate bag, found approximately 6 m north-northwest of this main feather group; both feather concentrations were fairly dispersed.
Array 4	1/16/2013	Mourning dove	11S	235610	3913174	Feather spot.
Array 4	1/16/2013	Mourning dove	11S	235588	3913193	Feather spot.
Array 4	1/16/2013	Mourning dove	11S	235616	3912749	Feather spot. Several hundred of feathers found.
Array 4	1/23/2013	Mourning dove	11S	235590	3913417	Feather spot. Only a few feathers, but one tail feather that was still mostly in the sheath; not a feather that would come from a live bird.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 4	1/23/2013	Mourning dove	11S	235624	3913517	Feather spot (>30 feathers).
Array 4	1/23/2013	Mourning dove	11S	235563	3913442	Older feather spot.
Array 4	1/23/2013	European starling	11S	235603	3912848	Feather spot (>50 body feathers).
Array 4	1/23/2013	Western meadowlark	11S	235761	3912701	Feather spot.
Array 4	2/13/2013	Western meadowlark	11S	235631	3912693	Feather spot at edge of row.
Array 4	2/13/2013	Mourning dove	11S	235767	3913293	Feather spot.
Array 4	2/13/2013	House finch	11S	235824	3913384	Feather spot (~15 body feathers).
Array 4	2/13/2013	Unknown small bird	11S	235737	3913347	Whole carcass. Fatality searcher informed of small dead bird on solar panel during weekly search. Bird was gone when searcher went to retrieve it 35 minutes later. Presumed to be removed by scavenger, potentially a CORA, which was seen in the area. Cause of death potential panel strike.
Array 4	4/24/2013	Horned lark	11S	235713	3913038	Feather spot (clump of ≥30 body feathers held together with dried skin).
Array 4	5/8/2013	House finch	11S	235724	3913524	Partial carcass (seven wing feathers still attached and one secondary).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 4	5/15/2013	Mourning dove	11S	235709	3913391	Feather spot (approximately ten primaries, six secondaries, and ≥30 wing and body feathers). Likely predated or scavenged by a mammal. Several feathers sheared off part way, as if bitten. Three clumps of feathers.
Array 4	6/12/2013	European starling	11S	235718	3912700	Feather spot (15 flight feathers).
Array 4	6/12/2013	House finch	11S	235767	3912695	Feather spot (23 flight feathers and ~50 contour feathers).
Array 4	6/19/2013	Yellow-rumped warbler	11S	235680	3912694	Feather spot (≥100 rump, contour, and wing covert feathers).
Array 4 control plot	4/17/2013	House finch	11S	236442	3912744	Feather spot (18 primaries, six other remiges, and ≥60 contour feathers).
Array 4 fence	2/13/2013	Mourning dove	11S	236303	3913354	Feather spot. Found outside of fence.
Array 5	1/16/2013	House finch	11S	236687	3913839[1]	Feather spot.
Array 5	2/6/2013	House finch	11S	236724	3913628	Feather spot.
Array 5	2/6/2013	Red-tailed hawk	11S	236683	3913857	Bones found (right leg and pelvis).
Array 5	3/27/2013	House finch	11S	236776	3913649	Feather spot (six primaries, two secondaries, and 20 breast feathers). Feathers sparsely spread across 3 m.

---

[1] Northing coordinate has been amended since the 2nd quarterly report was submitted, because this coordinate had been mislabeled.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 5	6/5/2013	House finch	11S	236779	3913577	Feather spot (three distinct clumps of feathers; ~40 breast and body feathers).
Array 8 Circuit 2	1/14/2013	Mourning dove	11S	233804	3912068	Feather spot.
Array 8 Circuit 2	1/21/2013	Mourning dove	11S	233641	3912191	Feather spot (four primaries and several body feathers).
Array 8 Circuit 2	1/21/2013	Mourning dove	11S	233630	3912302	Feather spot (several secondaries, coverts, and body feathers).
Array 8 Circuit 2	1/28/2013	Mourning dove	11S	234106	3911788	Feather spot (five primaries and >30 downy feathers).
Array 8 Circuit 2	1/28/2013	Mourning dove	11S	233543	3912244	Whole carcass. Found at preening site.
Array 8 Circuit 2	2/11/2013	Mourning dove	11S	233385	3912476	Feather spot (>20 body feathers, several flight feathers, and one clump of body feathers).
Array 8 Circuit 2	3/4/2013	House finch	11S	233416	3912277	Feather spot of partially intact whole wing, with five or more primary and secondary feathers each, and five or more body feathers.
Array 8 Circuit 2	4/15/2013	Western meadowlark	11S	233648	3912076	Partial carcass (wings and body, but no head). Could be red-tailed hawk (RTHA) kill. Two western kingbirds (WEKI) and one RTHA were observed earlier in day. RTHA was directly beside fence.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 8 Circuit 2	4/15/2013	Horned lark	11S	234052	3911694	Feather spot (one full wing, one partial wing, three breast feather clumps, and ≥50 loose body feathers). Feathers appear weathered.
Array 8 Circuit 2	7/17/2013	Great horned owl	11S	233957	3912424	Feather spot (two wings and >100 body feathers). Incidental fatality.[2]
Array 8 Circuit 2	7/22/2013	Horned lark	11S	234043	3911719	Feather spot (one primary and ~15 contour feathers).
Array 8 Circuit 2	8/5/2013	Horned lark	11S	233966	3911745	Feather spot (25–50 body feathers and several primaries). Found in charred substrate under panels and scattered throughout the tracker.
Array 8 Circuit 2	8/12/2013	Horned lark	11S	233976	3911740	Feather spot (~30 contour and flight feathers).
Array 8 control plot	3/4/2013	Mourning dove	11S	234418	3913321	Feather spot (two primaries together).
Array 1–2 fence	10/16/2012	Horned lark	11S	234527	3915080	Feathers and flesh hanging from fence, approximately 0.5 m off ground. One flight feather and flesh on ground right along fence.
Array 1–2 fence	10/30/2012	Mourning dove	11S	233399	3915720	Feather spot.
Array 1–2 fence	11/13/2012	Western meadowlark	11S	234418	3915494	Feather spot with beak and skull fragments.
Array 1–2 fence	12/4/2012	Mourning dove	11S	233852	3914441	Feather spot (≥20 body feathers).

---

[2] In the 4th quarterly report, this incidental fatality was reported as a long-eared owl on Figure 4, but was not included in the Appendix A summary of the weekly fatality search results. This species was later identified as a great horned owl.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1–2 fence	12/11/2012	Mourning dove	11S	233793	3914373	Feather spot.
Array 1–2 fence	1/15/2013	Western meadowlark	11S	234383	3914539	Feather spot.
Array 1–2 fence	1/22/2013	Mourning dove	11S	233620	3914498	Feather spot. Two feather spots separated by 23 m, but feathers appear to be from same individual. Largely contour and down feathers, with a single primary found. Feathers spread on either side of the fenceline.
Gen-tie Line	8/29/2012	Burrowing owl	11S	234398	3916178	Feather spot at base of Tower 11. Feathers possibly from burrowing owl fatality previously found on 7/18/2012.
Gen-tie Line	8/29/2012	Horned lark	11S	234255	3916437	Feather spot scattered to the west of the tower 12.

Gen-tie Line	10/31/2012	Fox sparrow	11S	234592	3914983	Feather spot between Towers 5 and 6, directly under powerline.
Gen-tie Line	10/31/2012	Mourning dove	11S	234408	3917851	Feather spot in tamarisk wetland. Suspected roosting/preening site.
Gen-tie Line	10/31/2012	Northern flicker	11S	234304	3917708	Feather spot between tamarisk wetland and Tower 17, directly below powerline.
Gen-tie Line	11/14/2012	Western meadowlark	11S	234580	3914699	Whole carcass between Towers 4 and 5, directly below powerline. Head dislocated at the neck. Some neck feathers plucked. No other obvious injuries. Cause of death possible line collision.
Gen-tie Line	11/28/2012	Horned lark	11S	234255	3916696	Feather spot (≥20 downy feathers).
Gen-tie Line	12/11/2012	Common raven	11S	234610	3915356	Whole carcass. Electrical burns on feet. Found ~5 m from base of Tower 7. Cause of death electrocution.
Gen-tie Line	12/11/2012	Common raven	11S	234640	3915393	Whole carcass. Head scavenged. Scales peeled back on legs. Found ~15 m east of Tower 7. Cause of death electrocution.
Gen-tie Line	12/12/2012	Mourning dove	11S	234382	3917819	Feather spot (≥200 feathers—downy, body, and flight feathers).
Gen-tie Line	12/19/2012	Mourning dove	11S	234255	3916534	Feather spot (flight, tail, and body feathers).
Gen-tie Line	12/19/2012	Western meadowlark	11S	234426	3916094	Whole carcass. Neck intact. Wings not broken but bones exposed on upper left wing. No sign of external injuries. Fresh. Cause of death likely line collision.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	1/9/2013	Horned lark	11S	234374	3917774	Feather spot (body feathers and several secondaries and primaries).
Gen-tie Line	1/9/2013	Western meadowlark	11S	234256	3916730	Old feather spot along fence line east of main road.
Gen-tie Line	1/9/2013	Mourning dove	11S	234270	3916541	Feather spot (several tail and body feathers, and some secondaries and primaries).
Gen-tie Line	1/16/2013	Horned lark	11S	234355	3917785	Feather spot (breast feathers).
Gen-tie Line	1/16/2013	House finch	11S	234603	3915112	Feather spot (two primaries).
Gen-tie Line	1/23/2013	Common raven	11S	234291	3917304	Feather spot (primaries, secondaries, and a few contour feathers). Found about 4.6 m from the Gen-tie Line. Feathers appear sheared off (feather shaft cut at an angle). Feathers are weathered.
Gen-tie Line	1/23/2013	Mourning dove	11S	234357	3916221	Feather spot (tail, body, and primary feathers). Fresh MODO scat at feather spot. Found <3 m from Gen-tie Line.
Gen-tie Line	1/23/2013	Horned lark	11S	234381	3917831	Feather spot (body, tail, primary, and secondary feathers). Found in wetland area directly under Gen-tie Line.
Gen-tie Line	1/23/2013	Horned lark	11S	234390	3917811	Feather spot (body, tail, primary, and secondary feathers). Relatively fresh. Found in wetland area.
Gen-tie Line	1/23/2013	Loggerhead shrike	11S	234390	3917750	Feather spot (mostly primaries with some body feathers). Very old kill. Discovered buried under litter in wetland area while searcher was cleaning up a fresh feather spot from a HOLA.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	1/23/2013	Loggerhead shrike	11S	234390	3917813	Feather spot (two fresh primaries). Found in wetland area.
Gen-tie Line	1/23/2013	Horned lark	11S	234394	3917816	Mixed feather spot of fresh and old feathers, potentially indicating other HOLA kills at same location. Blood found on branch near spot. Found near three previously documented fatalities.
Gen-tie Line	1/23/2013	Horned lark	11S	234358	3917772	Feather spot (body, tail, and flight feathers). Found just outside wetland area, under shrub.
Gen-tie Line	1/30/2013	Horned lark	11S	234384	3917825	Feather spot (>20 flight feathers and >40 body feathers). Found in tamarisk wetland.
Gen-tie Line	1/30/2013	Horned lark	11S	234482	3917744	Feather spot. Found in tamarisk wetland.
Gen-tie Line	1/30/2013	House finch	11S	234575	3914595	Feather spot (>20 flight feathers and >50 body feathers).
Gen-tie Line	1/30/2013	Horned lark	11S	234569	3914573	Feather spot (>20 body feathers).
Gen-tie Line	1/30/2013	House finch	11S	234568	3914514	Feather spot.
Gen-tie Line	1/30/2013	Horned lark	11S	234482	3917744	Feather spot.
Gen-tie Line	1/30/2013	House finch	11S	234394	3917875	Feather spot.
Gen-tie Line	1/30/2013	House finch	11S	234572	3914523	Feather spot (many tail and wing feathers, some body feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	1/30/2013	House finch	11S	234556	3914504	Feather spot (>10 flight feathers and >20 body feathers).
Gen-tie Line	2/6/2013	Mourning dove	11S	234318	3914093	Feather spot. West of old farm house. Very likely a heavily used preening site.
Gen-tie Line	2/13/2013	Mourning dove	11S	234255	3916582	Feather spot (several hundred feathers—flight and body feathers). Possibly scavenged by SJKF—SJKF scat found at spot. Feathers found in two piles about 5 m apart. A "trail" of feathers connected the two piles. Scat from two animals (SJKF and pig or coyote) present.
Gen-tie Line	2/13/2013	Western meadowlark	11S	234413	3918059	Feathers spot. Feathers scattered across 10 m.
Gen-tie Line	2/20/2013	Savannah sparrow	11S	234285	3916896	Whole carcass. No visible signs of injury, but found directly under powerline. Cause of death possible line collision.
Gen-tie Line	3/20/2013	Horned lark	11S	234279	3917067	Feather spot (≥15 primaries and secondaries and ≥30 body feathers). Found directly under the powerline. SJKF scat present near spot.
Gen-tie Line	3/25/2013	Common yellowthroat	11S	234598	3915248	Whole carcass. Fresh blood on carcass. Tail broken. No other major injuries observed. Cause of death possible line collision.
Gen-tie Line	3/27/2013	Mourning dove	11S	234333	3917755	Feather spot (five or more secondaries and ten or more body feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	4/3/2013	Mourning dove	11S	234270	3916745	Feather spot (four coverts and ten or more contour feathers). Spread across 5-m diameter.
Gen-tie Line	4/17/2013	Horned lark	11S	234291	3917588	Feather spot (20 flight feathers and 50 body feathers). Found directly under the powerline.
Gen-tie Line	4/17/2013	Horned lark	11S	234599	3915172	Feather spot (~20 primaries). Found directly under the powerline.
Gen-tie Line	4/23/2013	Nashville warbler	11S	234143	3913787	Whole carcass. Tip of beak broken, indicating likely collision. Cause of death possible line collision.
Gen-tie Line	4/24/2013	Warbler sp.	11S	234279	3917306	Feather spot (20 flight feathers, ≥30 body/breast feathers—all downy). Found at fenceline parallel to road.
Gen-tie Line	5/1/2013	Horned lark	11S	234437	3914300	Feather spot (partial wing, ≥20 flight feathers, and ≥50 body feathers—mostly downy). Found directly under the powerline.
Gen-tie Line	5/8/2013	Warbling vireo	11S	234450	3914310	Whole carcass, very fresh. Possible broken neck. Found directly under powerline. Cause of death possible line collision.
Gen-tie Line	5/22/2013	MacGillivray's warbler	11S	234515	3918720	Feather spot (11 primaries and part of wing).
Gen-tie Line	5/22/2013	Mourning dove	11S	234513	3918735	Feather spot (~100 body feathers and one primary).
Gen-tie Line	5/22/2013	Warbler sp.	11S	234277	3917091	Feather spot (~30 contour feathers).
Gen-tie Line	5/22/2013	Yellow warbler	11S	234631	3915389	Feather spot (eight flight feathers and ~50 contour feathers).
Gen-tie Line	5/22/2013	Swainson's thrush	11S	234258	3916622	Feather spot (~25 flight and 50 contour feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-Tie Line	5/29/2013	Horned lark	11S	234275	3917246	Feather spot (~100 body and 12 flight feathers). Found directly under the powerline.
Gen-tie Line	5/29/2013	Yellow-rumped warbler	11S	234265	3917142	Feather spot (~100 body and 15 flight feathers).
Gen-tie Line	5/29/2013	Horned lark	11S	234265	3917142	Feather spot (12 body and six flight feathers). Pig scat present.
Gen-tie Line	5/29/2013	Warbler sp.	11S	234296	3917715	Feather spot (12 flight and 30 body feathers). Found directly under the powerline.
Gen-tie Line	5/29/2013	Horned lark	11S	234713	3915513	Feather spot (15 flight feathers, some attached by tissue, and ~100 body feathers).
Gen-tie Line	5/29/2013	Western meadowlark	11S	234618	3918793	Feather spot (15 primaries and secondaries and 15 body feathers). One clump of wing feathers attached by flesh.
Gen-tie Line	5/29/2013	Warbler sp.	11S	234717	3915511	Feather spot (25 flight and 50 body feathers, some held together by tissue).
Gen-tie Line	5/29/2013	Common raven	11S	234570	3914533	Feather spot (three flight and ten body feathers).
Gen-tie Line	5/29/2013	Horned lark	11S	234582	3914885	Feather spot (~50 body feathers).
Gen-tie Line	5/29/2013	Mourning dove	11S	234497	3918687	Feather spot (eight flight and ten body feathers).
Gen-tie Line	5/29/2013	Yellow warbler	11S	234423	3918671	Whole carcass. Found directly under the powerline.
Gen-tie Line	6/5/2013	Unknown small bird	11S	234586	3914810	Feather spot. A small number of body feathers connected by tissue at base of Tower 5.
Gen-tie Line	6/5/2013	Horned lark	11S	234257	3916588	Feather spot (four flight feathers, one tail feather, and 15 body feathers).
Gen-tie Line	6/5/2013	Yellow-rumped warbler	11S	234589	3914953	Feather spot (16 flight feathers and ~100 body feathers). Found directly under the powerline.
Gen-tie Line	6/5/2013	Warbler sp.	11S	234295	3917690	Feather spot (13 flight feathers and 30 contour feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	6/5/2013	Warbler sp.	11S	234261	3916718	Feather spot (small clump of approximately ten body feathers stuck together with skin).
Gen-tie Line	6/5/2013	Unknown small bird	11S	234258	3916725	Feather spot (two tail feathers and one body feather). Found 5 m west of powerline.
Gen-tie Line	6/7/2013	Warbler sp.	11S	234615	3915267	Whole carcass. Found directly under the powerline.
Gen-tie Line	6/19/2013	Horned lark	11S	234643	3915468	Feather spot (~20 body feathers). Found ~90 m from the powerline. May not be associated with line.
Gen-tie Line	7/3/2013	Common yellowthroat	11S	234271	3917162	Feather spot (20 primaries and secondaries and ~70 body feathers). Nearly directly underneath the powerline.
Gen-tie Line	7/3/2013	Mourning dove	11S	234617	3918811	Feather spot (~20 primaries and secondaries, four tail feathers, and ~100 body feathers). Found scattered on hill southwest of Tower 22.
Gen-tie Line	7/31/2013	Mourning dove	11S	234279	3917054	Feather spot (numerous feathers from entire body).
Medium-voltage Overhead (MVOH) Line	1/30/2013	House finch	11S	234625	3913324	Decapitated carcass. Found outside fenced GKR site. Cause of death possible predation by LOSH.
MVOH Line	2/27/2013	Mourning dove	11S	236848	3913043	Feather spot (seven tail, a few primary, a few secondary, and ≥15 body feathers). Found ~250 m west of Array 6 edge, between second and third pole from start of MVOH Line west of Array 6. Multiple feathers found within a 2-m radius.
MVOH Line	3/13/2013	Barn owl	11S	238143	3912198	Feather spot (~12 wing feathers and two or three breast/body feathers). Mixed in and under Russian thistle piled against barbed wire.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
MVOH Line	4/1/2013	Common raven	11S	233898	3912970	Whole carcass. More than likely electrocuted on 3/28/2013, when a breaker blew out at the Substation. Electrocuted on/above coupler on the MVOH Line. May have arced across the lines.
MVOH Line	4/11/2013	Common raven	11S	233909	3912966	Whole carcass. Electrocuted at 8:30 AM at second tower to west, directly north of Array 8. Exit burn through neck, burn on belly. Singed feathers along left wing.
MVOH Line	4/17/2013	Horned lark	11S	234603	3913329	Feather spot (approximately nine primaries). Found under CORA nest on MVOH Line—nest is on powerline straight-away near Substation to the east.
MVOH Line	4/17/2013	Common raven	11S	234615	3913319	Feather spot (more than ten feathers). Difficult to collect because of wind. Located under CORA nest. Adults were lining the nest with white material. Found 100 m from the Operations and Maintenance facility.
MVOH Line	4/24/2013	House finch	11S	237860	3912838	Feather spot (ten contour and 15 flight feathers). Located directly under the powerline, ~20 m southwest of power pole.
MVOH Line	5/22/2013	European starling	11S	235550	3912671	Feather spot (part of right wing with primary and covert feathers).
MVOH Line	6/5/2013	Common raven	11S	234268	3913479	Feather spot (two flight feathers and one body feather). Found on road adjacent to tracker. Raven footprints present in the dust on the ground.
MVOH Line	6/5/2013	Common raven	11S	238155	3912221	Whole carcass. Dead juvenile seen hanging from nest, with pin and body feathers on ground.
MVOH Line	6/12/2013	European starling	11S	236683	3913043	Feather spot (approximately ten primaries and ten body feathers).
MVOH Line	6/19/2013	House sparrow	11S	233773	3915437	Feather spot (five flight and 15 contour feathers). Found directly under the powerline.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
MVOH Line	7/10/2013	Western meadowlark	11S	235656	3912671	Feather spot (~100 breast, tail, and flight feathers).
MVOH Line	7/10/2013	House finch	11S	236680	3913043	Feather spot (six flight and tail feathers and ~30 body feathers).
MVOH Line	7/10/2013	Short-eared owl	11S	233895	3912971	Partial carcass (lower foot and small part of tibia).
MVOH Line	7/31/2013	Horned lark	11S	233839	3911689	Feather spot (~30 contour feathers). Found directly under the powerline.

Appendix D. Foraging Zone and Taxonomic Group of Species Observed Within Project Elements During Weekly Fatality Searches: 16 August 2012 to 15 August 2013

Prepared per:

Avian And Bat Protection Plan for the California Valley Solar Ranch Project

U.S. Fish and Wildlife Service
Biological Opinion (81420-2011-F-0511)
San Luis Obispo County
Conditional Use Permit (DRC2008-00097)

28 March 2014

Executive Summary

Background

The California Valley Solar Ranch Project (CVSR Project) is a 250-megawatt photovoltaic solar power plant recently constructed within an approximately 4685-acre site (Project site), located mostly south of State Route (SR) 58, about 6.4 kilometers (km) east of Soda Lake Road, immediately north of the California Valley subdivision, in the Shandon-Carrizo planning area of San Luis Obispo County (Figure 1). The Conditional Use Permit for the CVSR Project required that an Avian and Bat Protection Plan be prepared and implemented to monitor the impacts of the CVSR Project on birds and bats after construction. In compliance with the resultant Avian and Bat Protection Plan, this Annual Postconstruction Fatality Report documents the number of avian and bat fatalities counted during postconstruction monitoring of the Project between 16 August 2012 and 15 August 2013.

Methods

H. T. Harvey & Associates (HTH) biologists conducted weekly surveys in the following CVSR Project elements: Array 1, Array 2, Array 2 Serengeti, Array 4, Array 5, Array 8, the Medium-voltage Overhead (MVOH) Line, and the Generation-tie (Gen-Tie) Line. During the reporting period, all arrays were surveyed each week at 20% of their total area, with the exception of Arrays 1 and 2, which were surveyed with 100% coverage to inform and strengthen our sampling methods. By collecting data at 100%coverage of these arrays, we were able to determine the spatial pattern of fatalities within the arrays and determine how much of the arrays would need to be surveyed to attain a given confidence level for developing an accurate fatality estimate for increasing our understanding of impacts to avian species from operating solar energy facilities. Further, these arrays were surveyed at 100% for a full year to detect whether or not the distribution of fatalities varied by season. For each of the arrays listed, biologists also surveyed portions of the surrounding fence. Additionally, to help identify the proportion of fatalities found that could be attributed to natural mortality rates, we surveyed control plots, located in Conservation Lands surrounding the CVSR Project site.

In addition to performing weekly surveys, HTH biologists conducted a series of repeat surveys: 5-day repeat surveys, in which biologists searched the same subset of a Project element for 5 consecutive days, and 1-day repeat surveys, in which biologists searched a subset of an area that was searched 1 day previously by either 5-day repeat searchers or weekly searchers. The purpose of these repeat surveys was to check the efficiency of searchers and evaluate the consistency of results; however, as reported herein, not all of the repeat surveys proved necessary.

To estimate the rate of avian and bat fatalities occurring on the site, we used Huso's Fatality Estimator (2010). In formulating a fatality estimate, it was necessary to determine 1) the rate of scavenging that occurs on the site, and 2) how well searchers find different-size carcasses in different amounts of vegetation cover. These determinations were made by 1) planting fresh carcasses of birds of various sizes and placing camera traps on them to identify scavenger species and the exact time of carcass removal, and 2) planting both carcasses and feather spots of different sizes in different vegetation classes while regular weekly and repeat surveys were taking place. Searcher-efficiency and carcass-removal rates were then used to adjust the annual count of fatalities to arrive at a site-wide fatality estimate.

Results and Discussion

Mean time to scavenging for all placed carcasses was 3.3 days and ranged from as little as 7 minutes to as long as 53 days. The carcass that persisted for 53 days was an outlier by 31 days; after removing this outlier from the analysis the mean time to scavenging was 2.8 days. Within 24 hours of placement, 54.4% of carcasses had been scavenged and 26.3% had been removed entirely (with no trace evidence). Within 7 days of placement, 86.9% of the carcasses had been scavenged, and 38.4% had been removed entirely. Ravens were the most common scavenger, and scavenged more than half of the carcasses placed. Ravens also scavenged carcasses the fastest, with a mean time to scavenging of 2.5 days (and a mean time of 1.5 days with the 53-day outlier dropped). Ravens scavenged three carcasses less than 1 hour after placement, and 72.5% of carcasses within 24 hours. San Joaquin kit foxes scavenged 20 carcasses, and had the second fastest scavenging time, with a mean time to scavenging of 3.6 days.

Of the carcasses placed, small carcasses were scavenged more quickly than large carcasses and more likely to be completely removed (80.6% of small birds scavenged were completely removed compared to 22.2% for large birds); consequently, only 19.5% of the small carcasses removed left evidence (partial carcass or feather spot) of the fatality, whereas, 77.7% of the large carcasses scavenged left evidence of the fatality. A logical extension of this finding is that the creation of a feather spot when a bird is preyed upon by an avian or mammalian predator is likely to occur at least as often as the creation of a feather spot during a scavenging event and feather spots created by depredated birds are likely to persist and be detected during searches at rates equal to feather spots created from scavenged carcasses.

The persistence of carcasses in the environment varied by season and Project element; carcasses placed in the control plots were scavenged more quickly than those along the Gen-tie Line, and carcasses placed in the arrays had the longest persistence time prior to being scavenged.

During the reporting period, searchers detected 94 of 177 (53%) of the fatality plants that were randomly placed in operational arrays, control plots, underneath overhead lines, and along fence lines across the CVSR Project site. Overall, searcher detection rates were higher below overhead lines and along fencelines (56%) than rates in the solar panel arrays (50%). Furthermore, the detection rate in surveyed rows within the arrays was slightly higher than in un-surveyed rows, which is expected as detectability generally declines with distance from the observer. Searcher efficiency was greatest during winter months (63%) and for large–sized carcasses (61% efficiency as opposed to 43% for small sized sparrows). Carcass size and visibility class, based on vegetation height and cover, were the most important indicators of how well searchers located fatalities. Scent detection dogs could be used to increase searcher efficiency rates, particularly where dense vegetation obscures fatalities, to improve the precision of the fatality estimates. If scent dogs prove significantly better during bias trials, we recommend considering the use of scent dogs to conduct fatality searches.

Causes of death were often difficult or impossible to determine from feather spots and carcasses found in the arrays. In a few cases, carcasses were found with no apparent injuries; in other cases, injuries (e.g., broken necks) indicated that a collision was the cause of death. Determining the cause of death from feather spots was even more difficult. We found feather spots on the ground near panels and on panels themselves. Fatalities may have occurred as a direct or indirect result of the presence of solar panels (e.g., a bird stunned by a collision with a panel can then be more easily predated), or they may indicate direct mammalian or avian predation. Solar panels likely contribute to direct and indirect causes of death for birds, but in many cases, it was not possible to determine cause of death. Because the ratio of feather spots to found carcasses was 20:3 during the reporting period, the inability to partition feather spots associated with collisions and feather spots stemming from predation has important implications regarding inferences that can be drawn from the fatality estimate.

Accounting for the spatial organization of avian fatalities is an important aspect of designing surveys and making decisions about future sampling, monitoring, and avoidance and minimization strategies. The geostatistical analysis of the dispersion of avian fatalities in Array 1 and Array 2 separately sampled at 100%, as well as in both arrays combined, indicates that the dispersion of fatalities is not significantly different from a random distribution. Knowing that fatalities are randomly distributed within arrays at the Project site is important for designing future sampling because there are no observable high concentrations (clumping) of avian fatalities that need to be taken into consideration. Moreover, a random dispersion pattern indicates that the probability of detecting an avian fatality should not change as a function of the amount of area (or number of tracker units) searched.

We used the fatality values from Arrays 1 and 2, which were searched in their entirety during the reporting period, to determine how the proportion of each array surveyed affects the accuracy of fatality estimates and confidence intervals.. Given the random dispersion of avian fatalities seen during the study period, and the error analysis for a given area searched, we recommend reducing monitoring to 20% of the total area in each array or array group. Also, each surveyed sample should comprise 30–35 tracker units; to meet this requirement, small arrays (e.g., Array 5) should be grouped with other small, neighboring arrays so that 20% of a given set comprises at least 30 tracker units.

On this Project site, fatalities rates were not high enough to obtain accurate samples during 1-day and 5-day repeat surveys from such small survey areas. As a result, we recommend discontinuing the 1-day and 5-day repeat surveys. We recommend that daily searches generally not be conducted to obtain a fatality estimate because they are labor intensive and labor is generally offset by surveying smaller areas. Given the tradeoff between area covered and frequency of searches, it is better to conduct regular weekly searches of a larger proportion of the site. Daily searches would be most useful if they are necessary to answer specific research questions, for example linking fatalities to weather patterns or to test a deterrent method or some other form of mitigation where knowing more precise timing of fatalities is important, but data gathered for answering these questions should not be used to obtain a site-wide estimate.

We recommend avoiding multiple searches of the same area at different time intervals. If surveys are conducted at various search intervals on the same area to answer research questions, we recommend that the different search strategies be designed to avoid interfering with each other. For example, daily searchers would not collect fatalities so they will still be present for weekly searchers to find.

A total of 357 fatalities were found during surveys of Project elements between 16 August 2012 and 15 August 2013; and an additional 11 fatalities were observed during surveys of control plots within conservation lands. It is important to note that this total comprises observations obtained during clearance surveys, weekly surveys, and 1-day and 5-day repeat surveys. The total number of fatalities observed at various Project Elements, consequently, may be larger than the sample sizes used to conduct overall fatality estimates for Project Elements because fatalities older than the search interval and fatalities found during clearance surveys and 5-day repeat surveys are not used to calculate the overall fatality estimates. Fatality estimates based on weekly searches and 5-day repeat searches were calculated separately.

The majority of fatality species represented year-round avian residents. In total, we found fatalities of 31 different avian species. Nearly all of the species utilize a terrestrial foraging zone; the two exceptions were a single American coot (*Fulica americana*) found along the Gen-tie and a single tree swallow (*Tachycineta bicolor*) found within a control plot. Horned larks, house finches (*Carpodacus mexicanus*), and mourning doves accounted for the greatest proportion of fatalities. Horned larks and mourning doves commonly roost and nest under the solar panels, and the two species combined represent 63% of the total number of fatalities found within the arrays. Documented special-status species fatalities comprised burrowing owl (*Athene cunicularia*), short-eared owl (*Asio flammeus*), long-eared owl (*Asio otus*), and loggerhead shrike (*Lanius ludovicianus*) fatalities. The total count of special-status species fatalities was small compared to the overall count.

In general, we estimated fatalities to be more abundant in the spring and less in the summer. This pattern is likely associated with the peak avian activity in the spring and the subsequent decline in activity in the summer, both documented through onsite avian point counts (HTH 2013). Because birds were more active on the Project site in spring, predation rates and collision rates are likely to be higher.

The Gen-tie Line was the only Project element that was searched for a full year during this reporting period because Project construction was completed during 2012. Eighty-three fatalities were found along the Gen-tie line and, based upon scavenging rates and searcher efficiency, we estimated that 446 fatalities occurred along the Gen-tie during this reporting period. We recommend that linear controls should be used to evaluate fatality rates along both the Gen-tie and MVOH Lines. Point counts targeting both raptors and passerines should be conducted in arrays and along linear features, allowing comparisons to data on activity on the Conservation Lands. These counts and comparisons would indicate whether fatality rates are associated with species abundance.

Project elements became operational and began to be searched at different times of the year, and the number of tracker units surveyed differed among arrays. Therefore, direct comparisons of fatality rates among and between Project elements are not made in this first year's fatality report. At the conclusion of all fatality searches next year, HTH will have collected enough data to report on seasonal differences in fatality rates, differences among arrays, and estimated fatalities per megawatt (a measure of avian and bat impacts that can be used to compare effects among various energy generation facilities).

We estimated that 231 fatalities occurred over a full year in Array 1 (90% confidence intervals: 162, 382) based on 47 fatalities found, and 187 fatalities in the control plots (90% confidence intervals: 107, 367) based on 11 fatalities found. This resulted in an adjusted fatality range 90% confidence interval of 55-275 attributable to the array, or 0.83 to 4.167 fatalities per tracker per year. This corresponds to a mean rate of 7.34 (90% Confidence interval: 3.24 to 16.27 fatalities per MW per year, assuming 0.256MW per tracker).

There are several caveats to keep in mind when interpreting these estimates. As we reanalyze data with full years of surveys for the remaining arrays and control plots these estimates will likely change. Our sample area of control plots in this calculation was based on surveys of 22 tracker sized control plots, which we now know from resampling is a low sample size to calculate fatality rates from, especially for an area as large as the on-site conservation land at the CVSR Project. This is also a conservative adjustment, using only the lower bound of the confidence interval or minimum estimated number of background fatalities.

As we complete full years of surveys for the remaining arrays, this estimate will likely change. Furthermore, because the ratio of feather spots to found carcasses was 20:3 during the reporting period, the inability to partition feather spots associated with collisions and feather spots stemming from predation has important implications regarding inferences that can be drawn from the fatality estimate. We are examining relationships within the existing data set in an attempt to quantify the relative contribution of predation events to the overall fatality estimates.

Section 1.0 Introduction

Through adoption of Resolution #2011-119, the Board of Supervisors of San Luis Obispo County (the County) approved the California Valley Solar Ranch Project (CVSR Project) Conditional Use Permit (DRC 2008-00097) on 19 April 2011. The Conditional Use Permit is subject to the Conditions of Approval (COAs) set forth in Exhibit 6 attached to the Resolution.

The Conditional Use Permit allows High Plains Ranch II, LLC (and any successor in interest for the life of the CVSR Project) to construct and operate a 250-megawatt photovoltaic solar power plant within an approximately 4685-acre site (Project site), located mostly south of State Route (SR) 58, about 6.4 kilometers (km) east of Soda Lake Road, immediately north of the California Valley subdivision, in the Shandon-Carrizo planning area of San Luis Obispo County (Figure 1).

COA #58 of the Conditional Use Permit requires an Avian and Bat Protection Plan (ABPP) and an annual report detailing any Project-related bird or bat deaths or injuries detected during the monitoring study defined in COA #58c. To satisfy COA #58c, H. T. Harvey & Associates (HTH), on behalf of High Plains Ranch II, LLC, has prepared this postconstruction fatality report, which documents the number of avian and bat fatalities counted during Project postconstruction monitoring between 16 August 2012 and 15 August 2013.

One of the primary goals of this report is to provide estimates of the numbers of fatalities associated with different Project elements. To meet this objective, we used the Fatality Estimator (Huso 2010). In addition to performing regular weekly searches, we conducted searcher-efficiency trials to estimate the percentage of fatalities of different sizes found by searchers in both short and tall vegetation. To calculate the persistence of fatalities in the environment, we also conducted carcass-removal trials. The values we derived from both carcass-removal trials and searcher-efficiency trials were used in tandem with the results of our regular weekly searches to calculate estimated ranges of fatalities associated with different Project elements. Additionally, to obtain an estimate of background mortality levels, we conducted controlled searches in control plots located in onsite Conservation Lands. Finally, as a secondary, independent measure of fatalities, we conducted a series of repeat searches with more highly concentrated search intervals. This annual report presents methods, results, and a discussion of the searcher-efficiency trials, carcass-removal trials, regular weekly fatality searches, and all repeat fatality searches. Project elements searched during the reporting period were the Generation-tie (Gen-tie) Line; the Medium-voltage Overhead (MVOH) Line; Arrays 1, 2, 4, 5, and 8; the perimeter fences; and control plots associated with Arrays 1, 2, 4, and 8.

To determine the appropriate amount of sample area in which to conduct fatality searches for estimating total fatalities per year, we considered whether the spatial distribution of detected fatalities, as well as their temporal persistence, may vary according to the amount of area searched (or total number of tracker units searched). (Each tracker unit comprises 18 rows of solar panels, with 40 panels to a row.) Because of the complete survey effort (100% coverage) focused on Arrays 1 and 2 over the course of an entire year, we were able to provide a statistical assessment of how reduced area covered influences the uncertainty around our estimates, and recommend a level of survey coverage that would provide reasonable estimates).

Section 2.0 Methods

2.1 Field Methods

2.1.1 Weekly Fatality Searches

To estimate the total number of fatalities associated with different Project elements during the reporting period, we conducted a series of weekly fatality searches on different Project elements. Because the construction of different Project elements was completed at different times, fatality searches began at varying times in the year, depending on the Project element searched (Table 1). We documented a fatality event each time a carcass or a feather spot was found. We considered a feather spot a fatality if it had at least two or more primary flight feathers, five or more tail feathers, or ten or more feathers of any type concentrated together in an area 1 square meter (m^2) or smaller (Smallwood 2007).

Preening spots often have fewer feathers and are more spread out than feather spots associated with fatalities. Roosting areas rarely contain primary or secondary feathers, but are often dotted with droppings. In the solar arrays, we regularly observed flocks of mourning doves (*Zenaida macroura)*, and horned larks (*Eremophila alpestris*) roosting. Mourning doves exhibit a complex molt strategy, which can occur year round and includes preformative, prealternate, and definitive prebasic molts (Otis et al. 2008). Likewise, horned lark adults and first-year birds undergo a definitive prebasic molt at the end of the breeding season (typically the end of July) (Beason 1995). Searchers used their biological knowledge to determine whether or not feathers from mourning doves, horned larks, or other species known to be in a molt period should be recorded as a fatality. When feathers were determined to be part of a molt or roost spot, no data were taken.

We gave each fatality a unique incident number. Incident numbers were written as follows: YYYYMMDD-#. Each searcher recorded a unique set of numbers, so data can be traced back to individual searchers. To further verify species identifications, we took photos of each fatality, and when necessary, we consulted Scott and McFarland's Bird Feathers identification book (2010). For each fatality, we recorded location (using Universal Transverse Mercator [UTM] coordinates), time found, taxon, common name, four-letter alpha code, carcass condition, parts found, number and types of feathers, and estimated time since death. Whenever possible, we recorded information about the age and sex of the fatality, as well as scavenger type. Additionally, we gathered information on the size and spread of the feather spot and the surrounding substrate, vegetation height, and percent vegetation cover, as well as whether the fatality occurred in a searcher or non-searcher row (for fatalities found in the arrays). All carcasses and feather spots discovered by regular weekly searchers were removed.

Table 1. Fatality Search Commencement Dates by Project Element

Project Element	Date Fatality Searches Began	Survey Period (Days)
Gen-tie Line	6 June 2012	435
Array 1	20 September 2012	329
Array 2 (Serengeti portion only)	25 September 2012	63
Array 1 control plot	1 November 2012	287
Array 1 and 2 fence	25 September 2012	324
Array 2 North (including Serengeti) and South	27 November 2012	261
Array 2 control plot	30 October 2012	289
Array 8 (20% sample)	7 January 2013	220
Array 4 (20% sample)	9 January 2013	218
Array 4 control plots	6 February 2013	190
Array 4 fence (20% sample)	16 January 2013	211
Array 5 and fence (20% sample)	9 January 2013	218
MVOH Line	30 January 2013	197
Array 8 control plots	4 February 2013	192
Array 8 fence (20% sample)	20 May 2013	87

Note: The Serengeti portion of Array 2 was searched separately only until 27 November 2012, so the Survey period reflects the time when the Serengeti portion was sampled separately from the rest of Array2.

Weekly fatality searches were performed along the Gen-tie Line; MVOH Line; Arrays 1, 2, 4, 5, and 8; and the associated control plots and fences for each array. The design comprised sampling 100% of Array 1 and 2, Gen-tie line, MVOH line, and fences for Array 1 and 2. Twenty percent of Array 4, 5, and 8 were sampled as were the fences for Array 4, 5, and 8. Each week, we selected random start locations for each Project element using a random number generator. Random selection was based on tower numbers (for the Gen-tie Line), line segment (for the MVOH Line), numbered array corners (for the solar arrays), and numbered fence corners (for the perimeter fence).

A team of two biologists searched a 30-meter (m)-wide transect centered under the complete length of the Gen-tie Line. Because of the relatively shorter height of the MVOH Line, it was assumed that carcasses would have less potential to distribute over a wide area (HTH 2011); therefore, the transect area along the entire length of the MVOH Line was only 18 m wide. Each person searched half the transect width and half the tower or pole radial areas for both the Gen-tie and MVOH Lines. On the Gen-tie Line, each person searched a 15-m-wide transect for large birds and a 6-m-wide transect for small birds and bats. On the MVOH Line, each person searched a 9-m-wide transect for small and large birds.

In the arrays, biologists searched tracker units in teams of two. In each tracker unit, biologists walked into every other row of panels and visually scanned both the row walked and each adjacent row. To avoid crossing the drive arms of the tracker units, searchers turned around upon reaching the drive arm, and continued to scan the next row as they proceeded out of the row. Thus, although searchers walked only every other row, they visually scanned adjacent rows to ensure full coverage.

To determine background rates of mortality, control plots were established on adjacent onsite Conservation Lands (plots were within 1 km of Arrays 1, 2, 4, and 8). Each control plot had the same dimensions as a tracker unit (i.e. equivalent to 18 rows of solar panels, with 40 panels to a row). We used pin flags or wooden stakes to delineate mock panel trackers on the control plots, and searchers followed the same pattern and procedure used for searching the arrays. Control plots were not established for the 20% sample of Array 5 because the 20% search area for this array contained too few trackers to meet the control plot establishment guidelines set forth in the Avian and Bat Fatality Monitoring Plan for the California Valley Solar Ranch (Appendix A *in* HTH 2011; one control plot for 16 tracker units searched).

Fence segments surveyed for Arrays 1, 2, 4, 5, and 8 (100% of Array 1 and 2 fences, and 20% of Array 4, 5, and 8 fences) were each searched by one biologist. Each week, the biologist walked the inside portion of the fence while scanning a 6-m-wide belt centered on the fence. In some cases, the fences were not completely built until after weekly searches had already commenced. In these instances, fences were included only as part of the regular search routine after they were completely installed.

Because searches were conducted only on designated days as a part of the search protocol, a "make-up" search was not conducted if the search day was missed because of inclement weather. For estimating the total number of fatalities, the fatality model accounted for search intervals of different lengths due to missed surveys (e.g., if a weekly search day was cancelled because of rain, the search effort would resume the following week and for that search, the interval was 14 days, not 7 days).

2.1.1 5-day Repeat Surveys

In addition to regular weekly searches, two types of repeat surveys were conducted. The 5-day repeat surveys were designed to serve several functions: (1) to identify a portion of the fatalities missed by regular weekly searchers, (2) to give limited estimates of the permanence of both feather spots and carcasses, (3) to provide an independent estimate of site-wide fatalities, and (4) to help estimate carcass deposition rates. Five-day repeat surveys were conducted on all Project elements subject to regular weekly searches, with the exception of the Gen-tie Line, which was not included in the 5-day repeat surveys because it was assumed that small birds and bats would be unlikely to strike high-tension powerlines. Each of the remaining sites was subjected to 5-day repeat surveys once every 4 weeks, and surveys were organized so that a 5-day repeat was conducted for a different site each week.

During each 5-day repeat survey period, searchers covered the same 25% (Array 1, Array 2, and MVOH Line) or 5% (Arrays 4, 5, and 8) portion of a given Project element for 5 consecutive days. Repeat searches of arrays also included searches of associated perimeter fences and control plots. However, because of the size of Array 2 and staffing limitations, conducting a 5-day survey of both Array 2 Serengeti and Array 2 North and South was not feasible. Therefore, these portions of Array 2 were treated as separate sites for the purposes of 5-day repeat surveys.

Five-day repeat surveys were originally conducted in the same areas as regular weekly searches for all arrays. However, in June 2013, this protocol was changed, and new, non-overlapping areas were established for 5-day repeat surveys in Arrays 4, 5, and 8, to keep the search interval at a constant span of 7 days for all weekly searches. In Arrays 1 and 2, however, overlapping search areas were unavoidable because weekly searches encompass 100% of the arrays. Under the revised protocol, feather spots and scavenged carcasses were still collected on the fifth day of each 5-day repeat survey, but any intact carcasses found were used in the carcass-removal trials, and camera traps were placed by the carcasses to record the activity of scavengers and monitor the persistence of the carcass past the 5-day span of the repeat survey. Then, the first day of each 5-day repeat survey was treated as a clearance search, and all fatalities found on the first day were removed from further analysis.

2.1.2 1-day Repeat Surveys

One-day repeats (carcass-detectability bias-correction surveys) represent a second type of repeat search, designed to identify a portion of the fatalities missed by weekly searchers. Every other week, a 1-day repeat survey was conducted on the day following regular weekly searches. One-day repeat searches were also conducted after each 5-day repeat survey on either the last day of the 5-day survey or 1 day after completion of the 5-day survey. These repeat searches were conducted to provide further estimates of the detectability of small bird and bat carcasses. Each 1-day repeat survey covered a randomly selected 25% of all elements searched in the weekly or 5-day repeat survey. For example, the 1-day repeat survey of Array 2 included a search of 25% of the array, 25% of the fence, and 25% of the associated control plots.

2.1.3 Searcher-efficiency Trials

To calculate searcher efficiency (i.e., searchers' rate of success in detecting fatalities), we conducted a total of 22 searcher-efficiency trials between 5 September 2012 and 25 September 2013 (Table 2). Although several of these trials fall outside of the current reporting period for fatalities, we include the trial result herein because these data were essential to our overall fatality estimates.

Season was assumed to be a potential influence on searcher efficiency. Within the reporting period, we defined four unique seasons as follows: fall (16 August to 15 November), winter (16 November to 15 February), spring (16 February to 15 May), and summer (16 May to 15 August). We were excluded from operational arrays of the Project site between 26 June and 17 July 2013 for maintenance reasons; therefore, no searcher-efficiency trials were conducted during this period.

Table 2. Searcher-efficiency Trial Date, Associated Season, and Location

Date	Season	Location(s)
5 September 2012	Fall	Gen-tie Line
26 September 2012	Fall	Gen-tie Line
18 December 2012	Winter	Array 2
29 January 2013	Winter	Array 2
28 February 2013	Spring	Array 1
17 March 2013	Spring	MVOH Line
15 May 2013	Spring	Arrays 2 and 4; control plots
23 May 2013	Summer	Array 1; control plots; Gen-tie Line
31 May 2013	Summer	Arrays 4, 5, and 8; control plots; Gen-tie Line
5 June 2013	Summer	MVOH Line
11 June 2013	Summer	Array 2
20 June 2013	Summer	Array 1
8 August 2013	Summer	Arrays 1 and 2
22 August 2013	Fall	Arrays 1, 4, and 5
26 August 2013	Fall	Array 8
11 September 2013	Fall	Arrays 4 and 5; control plots; Gen-tie Line; MVOH Line
16 September 2013	Fall	Arrays 4, 5, and 8; control plots
17 September 2013	Fall	Arrays 2, 4, 5, and 8; control plots
18 September 2013	Fall	Arrays 4 and 5; Gen-tie Line; MVOH Line
19 September 2013	Fall	Arrays 1, 4, 5, and 8
20 September 2013	Fall	Arrays 4, 5, and 8
25 September 2013	Fall	Arrays 4 and 5; Gen-tie Line; MVOH Line

Each week during which searcher-efficiency trials were scheduled, we set out between two and eight "fatality plants" (i.e., carcasses or feather spots) in areas scheduled for searches. We arrived approximately 1 hour in advance of the searchers so that we could set out fatality plants without alerting the regular searchers they were being tested. We recorded a Global Positioning System (GPS) point for each fatality plant. We marked each fatality discreetly with tape or flagging so that searchers would know to report their finds as part of the controlled searcher-efficiency trial. We randomly selected locations for the fatality plants within the tracker units, control plots, and along the overhead lines and fences. Within the tracker units and control plots, we randomized placement between surveyed and un-surveyed rows, as well as with regard to distance and direction from structures.

During the week of 16–20 September 2013, we set out 10 to 40 fatality plants each day to capture missing combinations of explanatory variables (e.g., large feather spots in medium vegetation cover), which were needed to correctly assess our final fatality estimates for the Project site, but were not adequately sampled in previous searcher-efficiency trials. For this period, we used a stratified random sampling scheme: we purposefully selected predetermined habitat categories to increase the sample size for our overall parameter estimates in our final fatality model.

We used a total of 177 fatality plants (90 carcasses and 87 feather spots) throughout the course of all trials. The fatality plants were specimens of common species found on the CVSR Project site (Appendix A).

2.1.4 Carcass-removal Trials

To estimate how long carcasses persist in the environment (which influences their continued detectability over time), we conducted carcass-removal trials. We acquired avian carcasses from the onsite fatality searches and wildlife rehabilitation centers, and also collected them opportunistically (e.g., collected road-killed birds) under state and federal salvage permits. Whenever possible, we used species that naturally occurred on the site or in the surrounding area. Once a carcass was acquired, we limited its handling to reduce transfer of foreign scents to the carcass. We marked carcasses by attaching electrical tape or flagging to one leg, to differentiate them from naturally occurring fatalities. We varied the body sizes of carcasses to determine carcass-removal rates and scavenging outcomes for different sizes. Of the 99 carcasses that we placed, 62 were large (>100 grams [g]) and 37 were small (<100 g) (Appendix B).

Initially we placed carcasses at randomly chosen locations along the Gen-tie Line, in Arrays 1 and 2, and their associated control plots. After construction was completed for additional elements (i.e., arrays and the MVOH lines), carcass removal trials were also conducted in all those search area elements. We dropped carcasses from shoulder height and allowed them to fall naturally to the ground. We recorded each carcass location with a GPS unit, noted the direction and distance to the nearest tower (when carcasses were placed along the Gen-tie Line) or tracker number (when carcasses were placed in arrays). We took photos to document the position of the carcass. We placed Bushnell Trophy Cameras (Model 119436) within 1–1.5 m of the carcass on a t-post, facing north to avoid allowing sunlight to shine directly into the camera lens. To avoid "scavenger swamping" (saturating our study area with more carcasses than resident scavengers have the ability to remove) (Smallwood et al. 2010), we limited the number of carcasses in a search area at one time to four. We programmed cameras to take three pictures in quick succession after each trigger event; each camera had a 1-second refractory period. Each picture was stamped with the date and time.

We checked each carcass at least once per week, for up to 6 weeks, or until it was scavenged. If the carcass was scavenged, we collected all remaining feathers and signs of the carcass and removed the camera. We classified the carcass as removed if the carcass could not be located, and there were fewer than ten feathers of any type or fewer than two primary feathers remaining. To classify feather spots, we used the same criteria as regular weekly searchers. Therefore, we classified the scavenging outcome as "not removed" if there were ten or more feathers of any type, or two or more primary feathers or any flesh or bone remaining. If the carcass was no longer in front of the camera and was not readily apparent, we searched the surrounding area using a spiral search pattern. We started the search at the camera's location and spiraled out to 30 m from the camera. If the carcass had been moved to a new location within the search area, but was intact, we repositioned the camera on the carcass in its new location. At least once per week, we checked the camera batteries and Secure Digital (SD) memory storage cards. We replaced the batteries when there was less than half of the charge remaining, and we replaced the SD card when there were more than 2000 pictures.

For 22 of the carcasses that were removed, the time of scavenging was not captured by camera. For these carcasses, we recorded the time the carcass was last photographed and the first time a photograph was taken without the carcass present. For the purpose of our descriptive statistics, we then calculated the midpoint between these two times and used that as the time of scavenging.

2.2 Statistical Methods

Several issues must be considered when estimating fatalities. First, animals die at an unknown rate; the rate must be inferred from regular searches of a site. Second, fatalities persist for varying amounts of time. Third, fatalities are imperfectly detected by searchers. The need to accurately estimate fatalities given these variables has driven the development of several fatality estimation statistical methods (e.g., see Johnson et al. 2003, Smallwood 2007, and Huso 2010). All of these fatality estimation methods share a similar underlying model. Generally, the fatality estimation for a given site may be written as:

$$F=C/rp,$$

where the number of fatalities, F, is the quotient of the number of carcasses found, C, over the product of carcasses left unscavenged, r, and the proportion that an observer sees, p (Huso 2010).

The inputs for r and p are estimated in subgroups of covariates that will influence the detectability and persistence of each carcass, such as carcass size, vegetation height, and stage of decay or scavenging (i.e., feather spot versus carcass). Given the tendency for many fatality models to underestimate site-wide fatalities, we chose to use a fatality estimator written by Huso (2010), which was shown to outperform previous fatality estimation models by more accurately accounting for imperfect detectability. This model, the Fatality Estimator, was developed to estimate fatalities primarily for wind energy projects; however, it can be applied to other sources of fatalities, including powerlines and solar projects (Huso 2010). The estimator uses this conceptual framework of fatalities, combined with "bootstrapping" from models of r and p, to calculate variances and confidence intervals for estimates of fatalities. Bootstrapping is a statistical method used to create a distribution to assign measures of variance to estimates that use data for which the underlying distribution is either unknown or cannot be represented algebraically (Efron and Tibshirani 1986). Bootstrapping resamples the data with replacement, several thousand times, to create a distribution that may be used to infer information about the sample mean.

2.2.1 Estimating Carcass-removal Rates

We assessed carcass-removal rates using the following descriptive categories: seasonality, scavenger species, size of carcass, and search area.

Measurements of carcass-removal rates typically include one or more censoring values. A censoring value is used in statistics when a value is only partially known. For example, if a carcass was checked on day 7 and was present, and was checked again on day 10, and found to be missing, then the date of scavenging is unknown, and an interval censor would be used. Because we used camera traps, most scavenging times were known precisely, so data were not censored. However, for the 22 carcasses for which the moment of scavenging was not recorded, we applied interval censoring. Additionally, we applied right censoring to the carcasses that were removed but left feather spots behind, because the extended persistence time of the feather spots was unknown. Specifically, we assumed that all small feather spots (i.e., feather spots left from a small carcass) would last at least 15 days, and large feather spots would last at least 30 days, beyond scavenging.

There are four commonly used distributions of survival models that can be used in the Fatality Estimator for a value of *r*: exponential, Weibull, loglogistic, and lognormal. These four distributions have different rates and shapes of decay curves that attempt to model the survival of carcasses over a given search interval. We used Akaike's Information Criterion (AIC), corrected for finite sample size (AICc; Akaike 1973), to rank the fit of each survival model to our carcass-removal trial data. Because the time of death for found fatalities is unknown, the probability of persistence cannot be calculated exactly for each carcass, but it can be estimated from the selected survival model and bootstrapped to obtain a range of estimates of *r* for each carcass. Because of issues regarding our sample size of covariate combinations, we modeled carcass-removal time only as a function of carcass size.

2.2.2 Estimating Searcher Efficiency

The proportion of fatalities that an observer sees, *p*, is represented most simply by the following equation:

$$p = \frac{NumberObserved}{NumberAvailable}$$

The value of *p* may be affected by several covariates. Therefore, we calculated detection rates for the following descriptive categories and combinations thereof: seasonality, Project element type (i.e., arrays and lines), visibility (i.e., habitat characteristics), and the size of each carcass or feather spot that was planted.

To determine which of the above explanatory variables (or combinations of) best described detection rates, we compared multiple models within the Fatality Estimator statistical software (Huso 2010) using AICc. Beginning with a null model (no temporal or categorical variation), we used a bottom-up modeling approach to compare AIC values and find the most appropriate model structure by incorporating different combinations of explanatory variables.

We calculated detection as the proportion of found fatality plants over the total available number of plants. Any fatality plant removed by scavengers before biologists searched the area was not included in the analysis. We assessed detection rates temporally, spatially, and categorically.

Based on the search method used (i.e., line transects under overhead lines and along fencelines, versus patterned searches within rows in arrays), we grouped fatality plants together. Those in arrays and control plots were grouped together, and those along the overhead lines (i.e., the Gen-tie and MVOH Lines) and fence lines surrounding searched arrays were grouped together.

We analyzed the two fall periods (2012 and 2013) together. Only one period of data was available for each of the winter, spring, and summer seasons.

We assessed habitat characteristics (i.e., vegetation height and percent cover) within a 1-m² area surrounding each fatality plant to test detection rates based upon visibility. We initially categorized visibility into three classes, easy, moderate, or difficult visibility, based on vegetation height and percent cover (Table 3), however, once trials began, we realized that the abundance of difficult visibility classes on the site were very limited; therefore, for all analyses, we grouped moderate and difficult visibility classes together (Figure 2).

Table 3. Visibility Classifications Assigned to Categories of Vegetation Height and Cover

Vegetation Height	Vegetation Cover (%)	Classification
Low	0–50	Easy
Low	50–100	Moderate
Medium	0–25	Easy
Medium	25–100	Moderate
High	0–50	Moderate
High	50–100	Difficult

a) Easy Visibility **b) Medium Visibility**

Figure 2. Photographic Examples of Easy and Medium Visibility Classes, Based on Vegetation Height and Percent Cover.

We assigned each species of carcass to one of two size classes (small or large) based on weight (i.e., small = <100 g; large = >100 g). We also assigned a size class to each feather spot used as a fatality plant. A small feather spot was defined as feathers from a small to medium-sized bird, scattered sparsely in a ≤20 square centimeter (cm^2) area; a large feather spot was defined as feathers from a large bird in a small area (≤20 cm^2) or feathers from a small to medium-sized bird scattered densely in an area ≥20 cm^2.

2.2.3 Estimating Fatalities on the Project Site

The Fatality Estimator bootstrapping procedure calculates an adjusted fatality value for every fatality found based on search interval, searcher efficiency, and carcass persistence. These bootstrapped values are then summed, and a site total estimate and 90% confidence intervals are calculated for the site and each covariate combination assigned. The Fatality Estimator was developed for wind energy projects, and uses individual wind turbines as the sample unit of replication. To apply this tool to the CVSR Project, we used tracker units instead of turbines as the sample unit. For linear features (overhead lines and fences) where we sampled the entire length, we used the entire feature as the sample unit. For sites in which we searched less than 100% of the area, we divided these values by the proportion of area searched to extrapolate it to the whole array or linear feature.

2.2.3.1 Overall Fatality Estimates

We calculated weekly fatality estimates separately for each Project element. For the arrays, we set the tracker as the unit of replication, and for each array we calculated total estimates of fatalities, fatalities per tracker unit, and 90% confidence intervals. In Array 2, 36 tracker units within the Serengeti portion of the array were searched for 2 months before the rest of the array, so we calculated separate values for that period. For linear features on the site, such as the Gen-tie Line, MVOH Line, and fences, we estimated fatalities for the feature as a whole. Estimates are based on 5000 bootstrapped iterations. We calculated fatality estimates and confidence intervals for large and small birds and particular species, as well as calculating seasonal totals.

Owing to the constraints and assumptions of the Fatality Estimator; appropriately, we did not include every fatality found in our calculations. We did not include fatalities found during clearance surveys (the first survey of an area), or fatalities that we determined to be older than the search interval, because the correction for searcher efficiency does not take into account repeated chances of finding a fatality (Huso pers. comm.).

2.2.3.2 Fatality Estimates from 5-day Repeat Surveys

To calculate fatality estimates from our 5-day repeat surveys, we treated each 5-day period as an independent unit of replication. Because the first day of each search was a clearance survey, each repeat survey period effectively consisted of 4 consecutive search days. We used the Fatality Estimator to calculate fatality estimates and 90% confidence intervals for the search areas of the array covered during repeat surveys. We then divided these estimates and 90% confidence intervals by the proportion of the array searched to extrapolate to the entire array, and then divided this estimate by the proportion of days searched over the total number of days until next search period to extrapolate temporally to the whole month (Huso pers. comm.).

To calculate the rate of deposition of fatalities per tracker units per day, we divided the estimate for each 5-day repeat period by the number of tracker units searched, and by the number of days it was searched.

2.2.3.3 Error Assessment for Sampling Avian Fatalities

To guide future sampling at CVSR, an error assessment was conducted to determine what proportion of arrays should be monitored to determine a reasonable measure of avian fatality. This is the first study that we are aware of designed to estimate the number of avian fatalities at a large utility scale photovoltaic facility. One of the unknowns was what percentage of the entire facility needed to be surveyed to attain a given confidence level for determining an accurate fatality estimate. To collect data to determine this, we surveyed two large arrays, Arrays 1 and 2, with 100% coverage. We continued this level of effort for a full year in case the distribution of fatalities varied significantly by season.

Two steps were involved in developing the error assessment for the survey effort. The first step was to determine the spatial organization of avian fatalities across 100% of the area searched inside the two sample arrays, throughout the entire monitoring period (1 year). We estimated the mean and standard deviation of avian fatalities per tracker unit (each unit of tracking solar panels with 18 rows and 40 solar panels per row) for each array and for both arrays combined. Furthermore, using the individual fatality sampling points, we calculated the Global Moran's I index to characterize the spatial dispersion of avian fatalities within and among arrays. The Global Moran's I index is a direct assessment of the spatial autocorrelation of points in space and provides a statistical measurement indicating whether avian fatalities may be clumped, uniform, or not different from random. We conducted the geostatistical analysis of avian fatalities using ArcInfo version 10.0 and its geographic statistical toolbox.

The next step was to establish the relationship between percent area monitored and the variation in fatality estimates around a true value.. To accomplish this we focused on the coefficient of variation (i.e., "variance-to-mean ratio") as our metric of variation for describing the changes in the number of detected avian fatalities with increasing area searched. Because the coefficient of variation is a normalized measure of dispersion, this metric is well suited for assessing changes in the distribution of avian fatalities as a function of area searched. In other words, it accounts for the clumping of avian fatalities in space (among tracker units within an array) and is a better metric than the mean for describing changes in detection of avian fatalities.

Using the datasets of detected avian fatalities for Arrays 1 and 2, we constructed a statistical resampling function to understand the variation that would be introduced into the final avian fatality estimate by sampling less than the entire array. This function simulates a range of sample sizes (from one tracker unit to one fewer than the total number of tracker units); for each sample size, 3000 simulated data sets were generated from the original data. For each of these data sets, the total number of fatalities was summed. This number was then divided by the values determined to correct for searcher efficiency and carcass persistence time. This number was then scaled to the total number of tracker units per unit area tested (e.g., tracker units in Array 1). We calculated the coefficient of variation for each sample size by dividing the standard deviation of the sample by the mean. All resampling analyses were conducted in the statistical program R, Version 3.0.2 (R Development Core Team 2011).

Section 3.0 Results

3.1 Carcass-removal Trials

Between 15 October 2012 and 12 August 2013, we placed a total of 99 carcasses for carcass-removal trials. We placed camera traps on 95 of these carcasses, and were able to record the exact removal time and scavenger species for 77 (81.1%) of the carcasses placed that had a camera trap. Of the 99 carcasses placed, 43 (43.4%) were eventually removed either completely, or left insufficient evidence to be classified as a fatality in a regular weekly search. The remaining 56 (56.6%) carcasses were scavenged from the original location or within the search area, and left evidence behind in the form of feathers, skin, or a partial carcass.

Mean time to scavenging for all placed carcasses was 3.3 days and ranged from as little as 7 minutes to as long as 53 days (Table 4). The carcass that persisted for 53 days was an outlier by 31 days; the mean time to scavenging without it was 2.8 days. Within 24 hours of placement, 54.4% of carcasses had been scavenged and 26.3% had been removed entirely (with no trace evidence). Within 7 days of placement, 86.9% of the carcasses had been scavenged, and 38.4% had been removed entirely (Table 5).

Table 4. Mean Times and Range for Scavenging for Each of Five Categories: Total, Carcass Size, Season, Scavenger Species, and Search Area

	N	Mean Time to Scavenging (Days)[a]	Range[b]
Total	99	3.3 ± 6.7 (2.8 ± 1.7)[b]	7 min–53 days
Carcass Size			
Large	63	3.5 ± 5.0	7 min–22 days
Small	36	3.0 ± 9.3 (1.5 ± 3.1)	10 min–53 days
Season			
Fall	8	1.2 ± 1.7	2 hours–5.5 days
Winter	16	8.3 ± 12.8 (5.3 ± 5.6)	4 hours–53 days
Spring	40	2.7 ± 4.9	15 min–22 days
Summer	35	2.2 ± 3.0	7 min–12.5 days
Scavenger			
Common raven	51	2.5 ± 8.0 (1.5 ± 3.7)	7 min–53 days
San Joaquin kit fox	20	3.6 ± 4.3	11 hours–16.5 days
Coyote	5	4.5 ± 4.7	8.5 hours–13.5 days
Unknown	22	4.3 ± 5.2	30 min–18 days
Search Area			
Array	49	4.4 ± 8.5 (3.4 ± 4.7)	1.7 hours–53 days
Gen-tie Line	40	2.6 ± 4.4	10 min–18 days
Control plots	10	0.6 ± 0.7	7 min–2 days

Notes: Min = minutes.

[a] Mean time to scavenging is shown ± 1 standard deviation.

[b] Carcass that persisted for 53 days excluded.

[C] (Results) reflect values excluding the carcass that persisted for 53 days.

Table 5. Percentage of Carcasses Scavenged and Removed within 1 Day and 7 Days of Placement, by Body Size, Season, Scavenger, and Placement Area

	N	% Scavenged by 1 Day	% Removed by 1 Day	% Scavenged by 7 Days	% Removed by 7 Days
Total	99	54.4	26.3	86.9	38.8
Carcass size					
Large	63	47.6	7.9	82.5	15.9
Small	36	66.6	58.3	94.4	77.8

Gen-tie	40	62.5	35.0	35.0	87.5
Control plot	10	80.0	30.0	100.0	40.0

3.1.1 Effect of Scavenger Type

With our remote cameras, we were able to document four species of vertebrate scavengers during the carcass-removal trials: San Joaquin kit fox (*Vulpes macrotis mutica)*, common raven (*Corvus corax*), coyote (*Canis latrans*) and turkey vulture (*Cathartes aura*) (Figure 3). Ravens were the most common scavenger, and scavenged more than half of the carcasses placed. Ravens also scavenged carcasses the fastest, with a mean time to scavenging of 2.5 days (and a mean time of 1.5 days with the 53-day outlier dropped). Ravens scavenged three carcasses less than 1 hour after placement, and 72.5% of carcasses within 24 hours. Ninety-four point one percent of raven-scavenging events occurred within 1 week. Of the 51 carcasses scavenged by ravens, 37.3% were removed entirely. In total, ravens scavenged 32 large carcasses and 19 small carcasses.

Figure 3. Scavengers Documented in Carcass-removal Trials

Figure panels are as follows: (top left) a common raven removing a ruby-crowned kinglet 53 days after it was placed in an array, (top right) a San Joaquin kit fox removing a Brewer's blackbird from a control plot 4 days after it was placed, (bottom left) a coyote removing a barn owl carcass after 3 days, and (bottom right) a turkey vulture scavenging a red-tailed hawk carcass 7 days after it was placed.

San Joaquin kit foxes scavenged 20 carcasses, and had the second fastest scavenging time, with a mean time to scavenging of 3.6 days. Within 24 hours, 35% of the San Joaquin kit fox scavenging events had occurred, and 80% had occurred within 7 days (Table 5). San Joaquin kit foxes were more likely than ravens to remove carcasses without leaving trace evidence. Of the 20 carcasses scavenged, 60% were removed entirely (Table 6), and 13 of these were large-bodied birds.

Coyotes had the longest mean time to scavenging: 4.5 days. They scavenged five carcasses in total, all of which were large. In all but one case, there was enough trace evidence left from the scavenged carcass to be considered a fatality.

Finally, our remote cameras captured a turkey vulture scavenging the carcass of a red-tailed hawk (*Buteo jamaicensis*) 7 days after it was originally placed.

For the remaining 22 carcasses, the scavenger responsible was not photographed, because of camera malfunctions.

Table 6. Outcomes of Carcass-removal Trials

	N	Carcasses Removed (%)[a]	Carcasses Leaving Feather Spots (%)	Partial Carcass (%)[b]
Total	99	41.4	35.4	23.2
Carcass Size				
Large	63	22.2	44.4	33.3
Small	36	80.6	13.9	5.6
Season				
Fall	8	75.0	12.5	12.5
Winter	16	56.3	37.5	6.3
Spring	40	32.5	37.5	30.0
Summer	35	42.9	31.4	25.7
Scavenger				
Common raven	51	37.3	33.3	29.4
San Joaquin kit fox	20	60.0	30.0	10.0
Coyote	5	20.0	60.0	20.0
Turkey vulture	1	0.0	0.0	100.0
Search Area				
Array	49	36.7	38.8	24.5
Gen-tie Line	40	52.5	27.5	20.0
Control plots	10	40.0	30.0	30.0

Notes:

[a] “Removed” refers to all carcasses that left no sign, or too few feathers to be classified as a fatality.

[b] “Partial carcasses” are classified as any fatality that was partially removed but left trace amounts of bone or flesh behind.

3.1.2 Effect of Carcass Size

Of the 63 large carcasses we placed, 22.2% were removed entirely or left insufficient evidence to be considered a fatality. The mean time to scavenging for large carcasses was 3.5 days, with 47.6% scavenged within 24 hours and 82.5% scavenged within 7 days. Small carcasses were more likely to be removed: 80.6% were removed. Mean time to scavenging for small carcasses was 3.0 days when the carcass in this size class that persisted for 53 days was included, and 1.5 days when it was excluded. Within 24 hours, 66.6% of small carcasses were scavenged, and within 7 days 94.4% were scavenged.

3.1.3 Effect of Season and Search Area

We put out carcasses for carcass-removal trials during all four seasons, but the coverage across seasons was not equal: eight carcasses were placed in fall, 16 in winter, 40 in spring, and 35 in summer. The mean time to scavenging was longest in fall, and shortest in winter. The carcass that persisted for 53 days was placed in winter, but even after dropping that carcass from the analysis, scavenging time was still longest in winter. Mean scavenging times in spring and summer were 2.7 days and 2.2 days, respectively.

Carcasses placed in the control plots were scavenged more quickly than those along the Gen-tie Line (Figure 3). Carcasses placed in the arrays had the longest time to scavenging: 4.4 days. The carcass that persisted for 53 days was in an array; however, even when this carcass was dropped from the analysis, mean time to scavenging in the arrays was still the longest: 3.4 days.

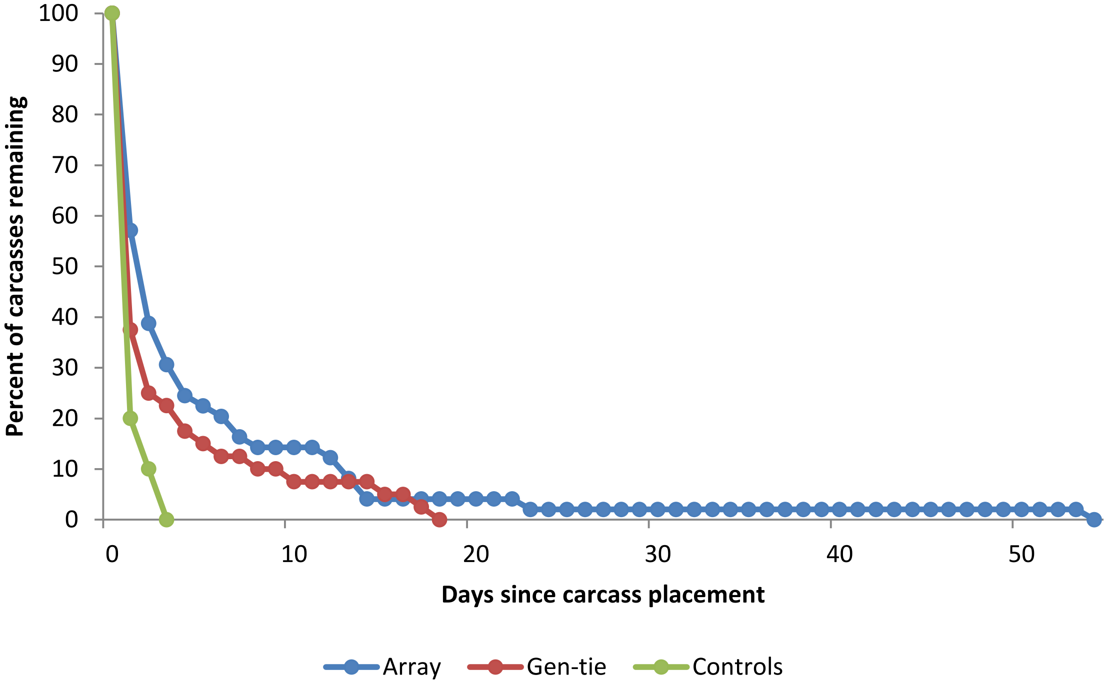

Figure 4. Percentage of Trial Carcasses Remaining Undisturbed by Scavengers per Day, Grouped by Search Area; N=99

3.1.4 Model Selection

Of the four selected survival models compared in the estimator, the lognormal model had the lowest AICc score (Table 7). For large carcasses, based on a search interval of 7 days, *r* = 0.92 (lower confidence interval =

0.86, upper confidence interval = 0.97). For small carcasses, $r = 0.42$ (lower confidence interval = 0.31, upper confidence interval = 0.55).

Table 7. AICc Values for Each of Four Distribution Models of Carcass Persistence

Survival Model for Carcass Persistence	AICc
Lognormal	253.00
Loglogistic	253.44
Weibull	259.44
Exponential	337.72

Because the difference in AICc values for the lognormal and loglogistic models was less than 2, these models were considered statistically equivalent (Akaike 1973), but we chose to use the lognormal model because it had a slightly lower AICc value.

3.2 Searcher-efficiency Rates

3.2.1 Overall Project Site Detection Rates

Over the course of 22 searcher-efficiency trials between September 2012 and September 2013, searchers detected 94 of 177 (53%) of the fatality plants that were randomly placed in operational arrays, control plots, underneath overhead lines, and along fence lines across the CVSR Project site. Small sample sizes in certain seasons prohibited us from using seasons as an explanatory variable for searcher efficiency. Nonetheless, we did see a sharp decrease (23%) in searcher efficiency between winter (N = 8) and spring (N = 10); efficiency then increased by 13% in summer (N = 17).

The detection rate of fatality plants in all areas with easy visibility was slightly higher (56%) than in those areas with medium visibility (51%). Searchers were slightly more efficient at detecting carcasses (56%) than feather spots (51%), and a greater proportion of large-sized fatality plants (61%) were detected by searchers compared to 43% of small-sized fatality plants in all areas (Table 8).

3.2.2 Detection Rates by Area and Explanatory Variables

Searcher detection rates were higher below overhead lines and along fencelines (56%) than rates in the solar panel arrays (50%). The detection rate in surveyed rows was slightly higher than in un-surveyed rows. Detection of fatality plants found in “easy” visibility areas along lines was higher (63%) than in “moderate” visibility areas (49%), but we found the opposite to be true in the arrays, where detectability in moderate areas was 8% greater than in easy areas. The detection rates of large fatality plants in arrays and along lines were essentially the same (approximately 62%), and large fatalities were easier to detect than small fatalities in both arrays (34%) and along lines (47%).

Detection rates within arrays, of large and small fatality plants in easy visibility areas, were 56% and 36%, respectively; these rates were lower than comparable rates along lines. In moderate visibility areas along lines, the detection rate of large fatality plants (48%) was lower than in easy visibility areas (76%), but we found that the detection of small fatality plants in moderate visibility areas along lines was slightly higher (6%) than in easy visibility areas. The detection rate of large fatality plants in moderate visibility areas in arrays (68%) was 20% higher than along lines, but the detection rate of small fatality plants in moderate visibility array areas (31%) was lower than the comparable rate along lines.

Detection rates were consistently higher for both large carcasses and feather spots in easy visibility areas than in moderate visibility areas, with the exception of the detection of small feather spots in medium visibility areas, which was 23% higher than in easy visibility areas.

Table 8. Overall Detection Rates from Searcher-efficiency Trials, September 2012 to September 2013

Category	Detection Rate	95% Confidence Intervals (lower, upper)	N
Overall	0.53	(0.46, 0.60)	177
Fall	0.54	(0.45, 0.62)	142
Winter	0.63	(0.31, 0.86)	8
Spring	0.40	(0.17, 0.69)	10
Summer	0.53	(0.31, 0.74)	17
Arrays/control plots	0.50	(0.40, 0.60)	90
Overhead/fence lines	0.56	(0.46, 0.66)	87
Surveyed row	0.51	(0.37, 0.65)	45
Unsurveyed row	0.45	(0.30, 0.62)	33
Large fatality size	0.61	(0.51, 0.70)	96
Small fatality size	0.43	(0.33, 0.54)	81
Carcass	0.55	(0.45, 0.65)	90
Feather spot	0.52	(0.40, 0.61)	87
Easy visibility	0.56	(0.45, 0.65)	90
Medium visibility	0.51	(0.40, 0.61)	87

Our top model in the Fatality Estimator had an AICc value of 238.55; this model indicated that carcass size best explains searcher-efficiency rates. However, the second best model, which differed by less than 2 (AICc

= 239.98), showed equal support for an additive effect between visibility class and fatality size (Table 9). We therefore adopted the additive effect structure for our detection rate in estimating fatalities, because visibility was shown in our descriptive statistics (see above) to be an important indicator of how well searchers did in locating fatalities.

Table 9. AICc Ranking of Searcher-efficiency Models

Searcher-efficiency Model	Explanatory Variables	AICc
size	Carcass size	238.55
size + visibility	Carcass size and visibility class	239.98
element + size + visibility	Project element, carcass size, and visibility	241.49
size x visibility	Carcass size and visibility class interaction	244.32
size x visibility + element	Carcass size and visibility interaction, and Project element	246
null	Null model	246.71
element	Project element	248.05
visibility	Visibility	248.32

3.3 Summary of Annual Fatalities

3.3.1 Results of Weekly Searches

A total of 357 fatalities were found during surveys of Project elements between 16 August 2012 and 15 August 2013; and an additional 11 fatalities were observed during surveys of control plots (each plot equivalent in size to a tracker unit: 18 rows of solar panels, with 40 panels to a row) within conservation lands (Table 10; Figures 5-9; Appendices C and D). It is important to note that this total comprises observations obtained during clearance surveys, weekly surveys, and 1-day and 5-day repeat surveys. The total number of fatalities observed at various Project Elements, consequently, may be larger than the sample sizes used to conduct overall fatality estimates for Project Elements because fatalities older than the search interval and fatalities found during clearance surveys and 5-day repeat surveys are not used to calculate the overall fatality estimates. Fatality estimates based on weekly searches and 5-day repeat searches were calculated separately.

The majority of fatality species represented year-round avian residents (Figure 10, Appendix D). In total, we found fatalities of 31 different avian species (Figure 11). Nearly all of the species utilize a terrestrial foraging zone; the two exceptions were a single American coot (*Fulica americana*) found along the Gen-tie and a single tree swallow (*Tachycineta bicolor*) found within a control plot (Appendix D). Horned larks, house finches (*Carpodacus mexicanus*), and mourning doves accounted for the greatest proportion of fatalities. Documented special-status species fatalities comprised burrowing owl (*Athene cunicularia*), short-eared owl (*Asio flammeus*), long-eared owl (*Asio otus*), and loggerhead shrike (*Lanius ludovicianus*) fatalities. The total count of special-status species fatalities was small compared to the overall count. One fatality was identified to genus, but not to species. Seven fatalities were not identified because partial skeletons and entrails or covert feathers were all that remained. These seven fatalities were placed into two "unknown" categories (unknown small passerine [6] and unknown [1]). Feather spots accounted for the vast majority of fatalities observed with a ratio of feather spots to carcasses (including partial carcasses) of 20:3.

Table 10. Summary of Avian Fatality Searches Conducted between 16 August 2012 and 15 August 2013; N= 357 for Project Elements, N = 11 for Control Plots

Project Element	Date of First Search	Number of Tracker Units[a] or Distance of Straight Line Search	Total Number of Fatalities Found Across all Survey Methods
Array 1	20 September 2012	66 trackers	52
Serengeti (only)[b]	25 September 2012	36 trackers	8
Array 1 control plots	30 October 2012	8 trackers	3
Array 1–2 fence	25 September 2012	5300 m	11
Array 2 North (including Serengeti) and South	27 November 2012	114 trackers	137
Array 2 control plots	1 November 2012	14 trackers	6
Array 4	9 January 2013	29 trackers	23
Array 4 control plots and fence	6 February 2013	4 trackers; 225-m fence	1 in control plot, 1 on fence
Array 5 and fence	9 January 2013	4 trackers; 56-m fence	5 in array, 0 on fence
Array 8	7 January 2013	54 trackers	13
Array 8 control plots	4 February 2013	6 trackers	1
Array 8 fence	20 May 2013	1600 m	0
Gen-tie Line	6 June 2012	4000 m	90
MVOH Line	30 January 2013	6800 m	17

[a] Tracker unit equals 18 rows of solar panels, with 40 panels to a row.

[b] The Serengeti portion of Array 2 was searched separately only until 27 November 2012, so the number of fatalities reported for the Serengeti reflects this initial period.

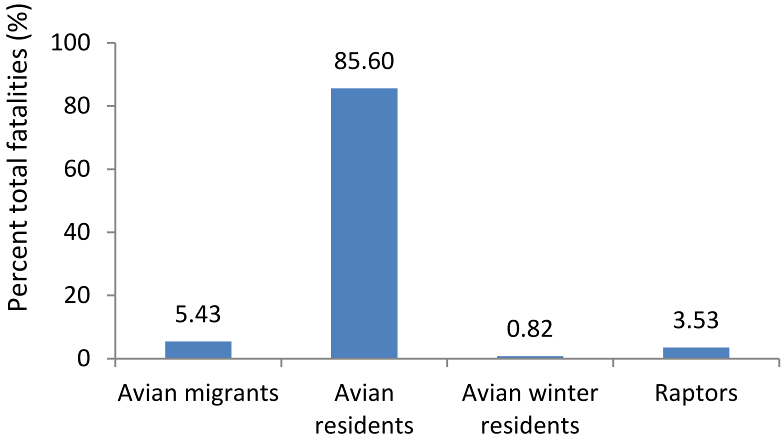

Figure 10. Percent of Total Fatalities in Each of Four Taxonomic Groups; N= 357

Groups were created based on knowledge of species typically found on the Project site at different times of the year.

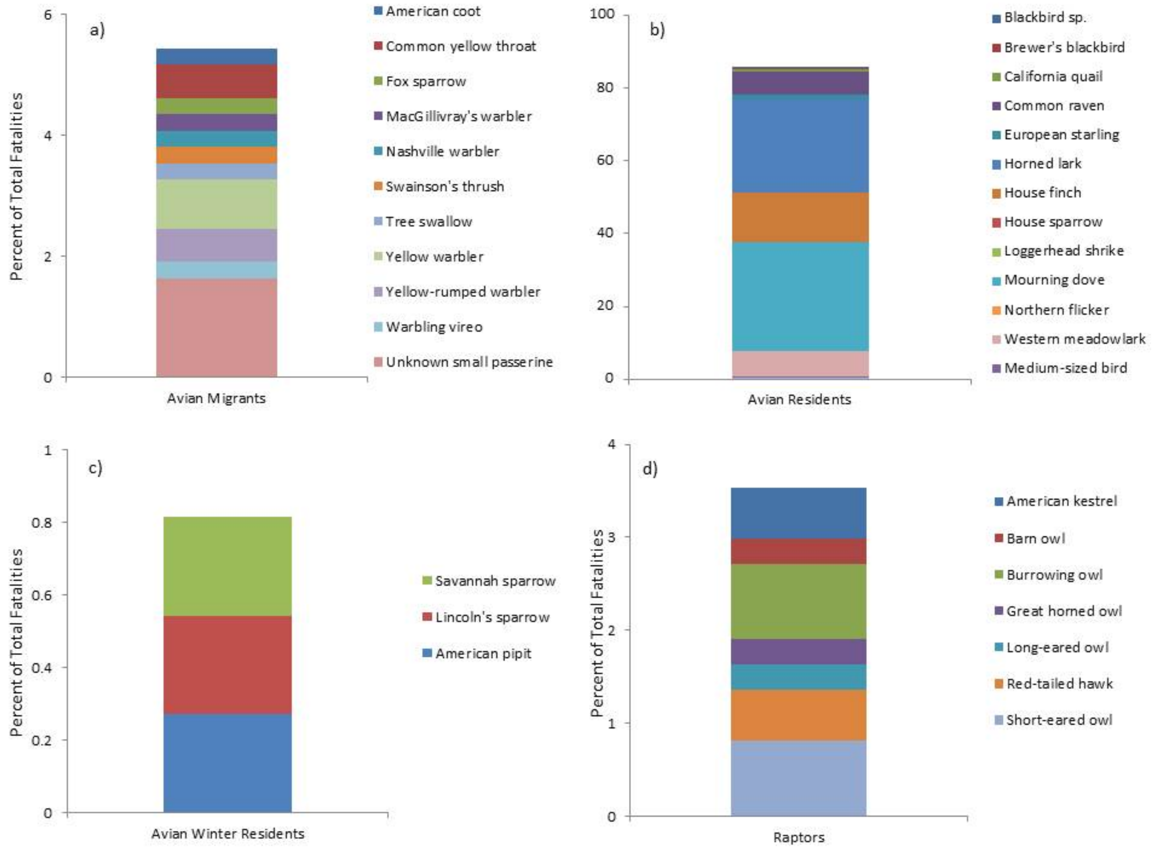

Figure 11. Percentage of Fatalities Belonging to Different Species, by Group; N= 357

Panels show: (a) fatalities by species of avian migrants, (b) fatalities by species of avian residents, (c) fatalities by species of avian winter residents, and (d) fatalities by species of raptors. Groups were created based on knowledge of species typically found on the Project site at different times of the year.

3.3.2 Results of 5-day Repeat Surveys

The first 5-day repeat surveys occurred on 29 October 2012. For the period of 29 October 2012 to 15 August 2013, 45 fatalities were found by repeat searchers. Thirty-six percent of all fatalities found by 5-day repeat searchers were mourning doves (Figure 12).

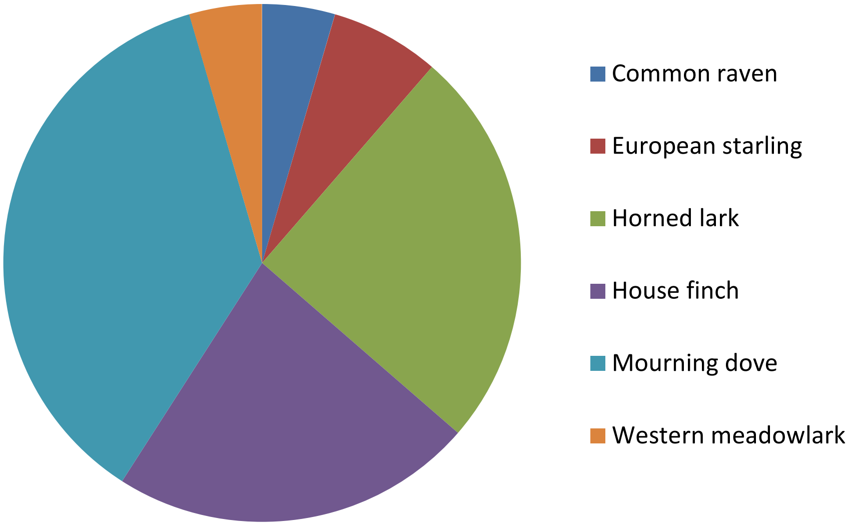

Figure 12. Total Fatalities Found during 5-Day Repeat Surveys, by Species; N= 45

3.3.3 Results of 1-day Repeat Surveys

3.3.3.1 1-Day Repeat Surveys of Weekly Search Areas

One-day (twice monthly) repeat surveys of weekly search areas began in the third quarter of the reporting period (i.e., in March 2013). In total, 16 fatalities were found by 1-day repeat searchers. Of these 16 fatalities, 25% were horned larks (Figure 13).

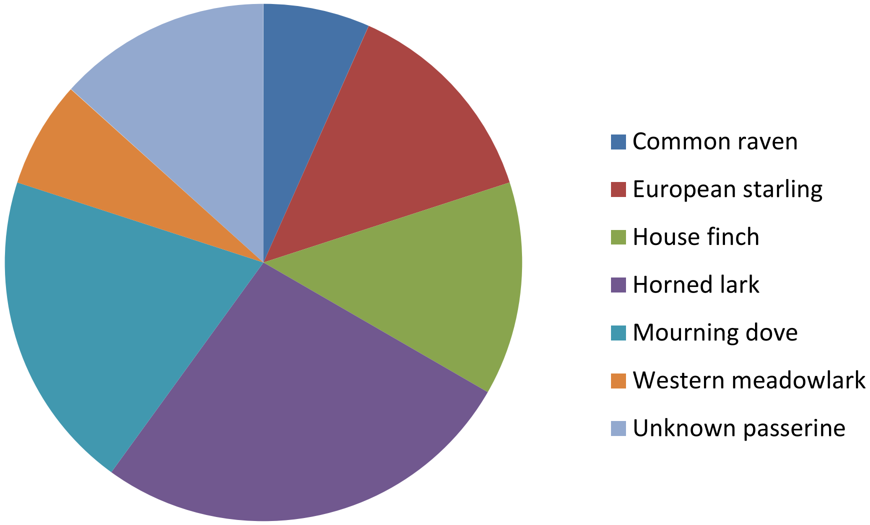

Figure 13. Total Fatalities Found during 1-day Repeat Surveys of Regular Weekly Search Areas, by Species; N= 16

3.3.3.2 1-Day Repeat Surveys of 5-Day Repeat Survey Areas

One-day repeat surveys of 5-day repeat areas also began in the third quarter of the reporting period. Between the third and fourth quarters, only one fatality was found during 1-day repeat surveys of these areas. This fatality was the feather spot of a common raven, found in Array 4.

3.3.4 Electrocutions

Although the cause of death is often difficult to determine, there were four clear cases of electrocution found during the reporting period. An additional two cases of electrocution were found the day before the period began, 15 August 2012. Although outside the official reporting period and excluded from all other analyses, we include mention of these deaths. All six electrocuted animals were ravens, and all electrocutions occurred on overhead lines, rather than in energized arrays. These cases are described in more detail below.

At Tower 7 along the Gen-tie Line, four common ravens were clearly electrocuted in two separate events on August 15 2012 and on 11 December 2012, as evidenced by scorch marks on their feet, and leg scales that were detached and curled. Tower 7 was evaluated and retrofitted during a plant outage on 22 January 2013 to prevent avian electrocutions. Changes to the tower conductor design to prevent electrocution included insulation of exposed conductors in configurations that could potentially create a ground-to-phase connection through a bird. No avian mortalities caused by electrocution related to Tower 7 have been observed since the correcting retrofit.

In April 2013, two ravens were found electrocuted along the MVOH Line. One bird had a clear exit burn through its neck, and singed feathers. The riser poles were temporarily modified to reduce the potential for further electrocutions until long-term remediation could be performed. NRG, SunPower, and Bechtel each consulted with experts on Avian Power Line Interaction Committee (APLIC) guidelines. Based on the consultations, perch diverters, squirrel guards, insulation, and covers were installed, and ground wires were relocated to minimize the potential for ravens or raptors to make contact between two energized phases or an energized phase and the ground at all potential contact points on the riser poles. These improvements were made to all Project MVOH Line riser poles. No further fatalities have occurred as a result of electrocution since these changes were made to the MVOH Line.

3.3.5 Tamarisk Pond

An 80-m section of the Gen-tie Line runs directly over a wetland consisting of a pond lined with saltcedar (*Tamarix ramosissima*). Because a large colony of red-winged blackbirds (*Agelaius phoeniceus*) and other species, such as tricolored blackbirds (*Agelaius tricolor*), a California species of special concern, nest in the wetland during the breeding season, we were unable to search this wetland at times during the reporting period. We stopped searching the pond on 15 March 2013, at the start of the breeding season. Also, because of stark differences in both bird activity and searcher efficiency in this area, we excluded the wetland from fatality estimates. Ten fatalities were found in this area: one long-eared owl, eight horned larks, and one lark sparrow.

3.4 Fatality Estimates from Weekly Searches

For the arrays and control plots, our estimates of the number of fatalities found per tracker unit during the search interval range from 5.68 in Array 2 to 0.95 in Array 8 (Table 11). For Project elements that were linearly searched (i.e., fences and overhead lines), our estimates of fatalities vary from 47 total fatalities along the fence around Arrays 1 and 2 to 446 along the Gen-tie Line (Table 12).

The Gen-tie Line was the only Project element that was searched for a whole year during this reporting period; therefore, this Project element is the only one for which we can accurately estimate seasonal fatality effects for the entire year. Contrary to our initial predictions, the number of small passerine carcasses found along the Gen-tie Line was much greater than the number of large birds and raptors found along the line (Table 13).

Table 11. Overall Fatality Estimates from Weekly Searches and 1-Day Repeat Searches of Nonlinear Areas, Using Wildlife Fatality Estimator, 16 August 2012 to 15 August 2013.

Site	Survey Period (Days)	Number of Fatalities Found in Sample Area	Estimated Number of Fatalities per Tracker Unit	90% Confidence Intervals (No. fatalities per tracker unit)	Estimated Number of Fatalities for Project Element	90% Confidence Intervals (Total no. fatalities)
Array 1	324	41	3.21	2.26, 5.35	212	150, 354
Array 2	261	125	5.68	4.17, 9.10	648	476, 1038
Array 2 Serengeti	63	8	1.02	0.69, 1.74	37	25, 63
Arrays 4 and 5	218	26	2.77	2.03, 4.25	449	329, 689
Array 8	220	11	0.95	0.55, 1.72	258	150, 464
Arrays 1 and 2 control plots	289 and 287	9	2.69	1.54, 5.35	60	34, 118
Arrays 4 and 8 control plots	190 and 192	2	0.73	0.55, 1.12	8	6, 12

Notes: Number of fatalities found in sample area does not include fatalities found during 5-day repeat searches or clearance searches, or carcasses older than the search interval. The size of the array and number of searches conducted vary by array, so results are not directly comparable. Survey Period (days) is the number of days from the onset of surveys at each site until 15 August 2013. Refer to Table 10 for a full list of the number of tracker units per array and dates searched. The numbers of estimated fatalities are rounded up to the nearest whole number. Estimates made based on fewer than five fatalities should be interpreted with caution.

Table 12. Overall Fatality Estimates from Weekly Searches and 1-Day Repeat Searches of Linear Areas, Using Wildlife Fatality Estimator, 16 August 2012 to 15 August 2013

Site	Number of Fatalities Found in Sample Area	Estimated Total Number of Fatalities	90% Confidence Intervals
Array 1–2 fence	11	47	35, 74
Array 4 fence	1	NA	NA
Array 5 fence	0	NA	NA
Array 8 fence	0	NA	NA
Gen-tie Line	83	446	343, 682
MVOH Line	14	71	51, 114

Notes: Number of fatalities found does not include fatalities found during 5-day repeat searches or clearance searches, or carcasses older than the search interval. The length of the line or fence and the number of searches conducted vary by Project element, so results are not directly comparable. The numbers of estimated fatalities are rounded up to the nearest whole number. Refer to Table 1 for full list of dates and survey lengths.

Table 13. Fatality Estimates from the Gen-tie Line by Season and Fatality Class

	Number of Fatalities Found	Estimated Total Number of Fatalities	90% Confidence Intervals
Fatality Class			
Large	21	44	38, 58
Small	69	403	303, 629
Season			
Fall	18	87	68, 128
Winter	17	69	54, 100
Spring	37	214	160, 339
Summer	18	78	60, 119

Note: Numbers of estimated fatalities are rounded up to the nearest whole number.

Finally, although we do not have a full year's worth of data to report for the remainder of the Project elements, both of the overhead lines and Arrays 1, 2, 4, 5, and 8 were all searched in spring and summer, so we were able to compare estimates from these two periods among different Project elements. The estimated number of fatalities per kilometer was much higher for the Gen-tie Line than the MVOH Line in both spring and summer (Table 14). The highest estimated number of fatalities for arrays was 2.65 per tracker unit (Array 2 in spring), and the lowest estimated number of fatalities was 0.11 per tracker unit (Arrays 4 and 5 in summer).

Table 14. Fatality Estimates from the Arrays and Overhead Lines by Season, per Tracker Unit or Kilometer

Project Element	Season[a]	Number of Fatalities Found in Sample Area	Estimated Number of Fatalities (per tracker unit or km)[b]	90% Confidence Intervals (per tracker unit or km)	Estimated Total Number of Fatalities for Project Element	90% Confidence Intervals (Total no. fatalities)
Array 1	Spring	10	0.9	0.46, 1.75	60	31, 116
	Summer	9	0.67	0.32, 1.35	45	21, 89
Array 2	Spring	57	2.65	1.87, 4.37	303	213, 498
	Summer	12	0.69	0.34, 1.38	79	40, 158
Arrays 4 and 5	Spring	6	0.87	0.33, 1.77	141	53, 287
	Summer	1	0.11	0.09, 0.37	18	14, 60
Array 8	Spring	3	0.26	0.08, 0.55	70	23, 150
	Summer	3	0.46	0.17, 1.22	124	48, 329
Array 1 and 2 control plots	Spring	4	0.97	0.27, 2.19	22	7, 49
	Summer	1	0.59	0.4, 2.45	13	9, 54
Array 4 and 8 control plots	Spring	2	0.73	0.55, 1.12	8	6, 12
	Summer	0	0	NA	NA	NA
Gen-tie Line	Spring	37	54	40, 85	214	160, 339
	Summer	18	20	15, 30	78	60, 119
MVOH Line	Spring	9	7	5, 10	41	31, 65
	Summer	5	5	4, 8	30	21, 50

Notes:

[a] Summer estimates may be artificially low because searches were not conducted during July due to maintenance work in the arrays.

[b] Estimates are given per tracker unit for arrays and control plots, and per kilometer for overhead lines.

3.5 Fatality Estimates from 5-day Repeat Surveys

After removing from the analysis all fatalities that had been missed by previous searchers or were cleared on the first day of the 5-day repeat survey, there were 22 fatalities remaining in the repeat-survey fatality analysis (20 in arrays, one along the MVOH Line, and one along the Array 1–2 fence).

Three additional fatalities had been found in control plots during 5-day repeat surveys, but two were found during clearance activities, and the third was judged to be older than the search interval, so fatality estimates could not be calculated for control plots from data collected during the 5-day repeat surveys.

For the arrays, estimates of fatalities ranged from 405 in Array 8 to 1995 in Arrays 4 and 5 (Table 15). Because the 5-day repeat surveys were started during different seasons in different arrays, the estimates shown in Table 15 are not directly comparable.

Table 15. Number of Surveys, Number of Fatalities Found, and Estimates of Total Fatalities per Element, Based on 5-Day Repeat Searches

Project Element	Number of Surveys	Number of Fatalities Found in Sample Area	Estimated Number of Fatalities for Project Element	90% Confidence Interval
Array 1	10	5	489	191, 1005
Array 2	7	6	628	464, 982
Array 2 Serengeti	11	3	336	224, 532
Arrays 4 and 5	7	4	1995	1283, 3420
Array 8	7	2	405	405, 539
Array 1–2 fence	11	1	84	84, 140
MVOH Line	4	1	111	84, 168

Note: Estimates for elements in which fewer than five fatalities were found should be interpreted with caution.

The rate of deposition of fatalities per day per tracker unit varied among arrays, from 0.007 fatalities per day per tracker unit in Array 8 to 0.063 fatalities per day per tracker unit in Arrays 4 and 5 (Table 16).

Table 16. Fatality Deposition Rates for Arrays and Linear Features

Project Element	Fatalities per Day (per tracker unit or per km)[a]	90% Confidence Interval
Array 1	0.026	0.01, 0.053
Array 2	0.041	0.029, 0.064
Array 2 Serengeti	0.028	0.02, 0.046
Array 4 and 5	0.063	0.039, 0.103
Array 8	0.007	0.006, 0.009
Array 1–2 fence	0.052	0.04, 0.073
MVOH Line	0.131	0.088, 0.219

Note:

[a] Fatality estimates are given per tracker unit for arrays, and per kilometer for fences and overhead lines. Estimates for Array 4, 5, and 8 fences are not included because of insufficient sample sizes (i.e. 0 or 1 observed fatalities).

3.6 Error Assessment Results

The geostatistical analysis of the dispersion of avian fatalities in Array 1 and Array 2 separately, as well as in both arrays combined, indicates that the dispersion of fatalities is not significantly different from a random distribution (Table 17). Knowing that fatalities are randomly distributed within arrays at the Project site is important for designing future sampling because there are no observable high concentrations (clumping) of avian fatalities that need to be taken into consideration. Moreover, a random dispersion pattern indicates that the probability of detecting an avian fatality should not change as a function of the amount of area (or number of tracker units) searched.

Table 17. Descriptive Statistics for Avian Fatalities per Tracker Unit and Results of a Point-pattern Analysis for Detecting Spatial Autocorrelation:
Moran's I Test for Assessing the Dispersion of Avian Fatalities

Project Element	Number of Tracker Units	Sum	Mean ± SD	Moran's I (I, Z, *P*[1])	Spatial Dispersion
Array 1	66	52	0.79±0.81	-0.12, -0.81, 0.42	Random
Array 2	114	147	1.29±1.45	0.09, 1.14, 0.25	Random
Arrays 1 and 2	180	199	1.11±1.62	0.09, 1.29, 0.19	Random

Notes: SD = standard deviation, I = statistical measure of spatial autocorrelation, Z = number of standard deviations away from the mean

[1] *P* values indicate no significant difference from a clumped distribution.

Figure 9 illustrates the change in variation in fatality estimate as a function of the number of tracker units sampled. The only source of variation in this plot is the difference in number of tracker units sampled (which indicates carcasses occurred with a random dispersion with a mean and standard deviation of 1.11±1.62 fatalities per tracker unit); the plot does not include any variation generated by other processes (e.g., carcass persistence). The resampling analysis suggests that sampling 20% of the total area (represented by "Number of Trackers Sampled" in the figure) is sufficient to provide a reasonably precise estimate of the Project site fatality rate, with sampling equitably spread throughout the site to ensure a spatially representative overall sample. This analysis suggests that sampling 30–35 tracker units within an array would be sufficient to capture an index of avian fatality.

In sum, given the significant random dispersion of avian fatalities derived from the study period, and the resampling analysis of the coefficient of variation as a function of area searched, we consider it acceptable to monitor 20% of the total area of an array, or collective groups of small arrays at the CVSR Project. Additionally, each sample of an array should comprise 30–35 tracker units, so small arrays (e.g., Array 5) should be combined with other small neighboring arrays, so that 20% of a given set comprises at least 30 tracker units.

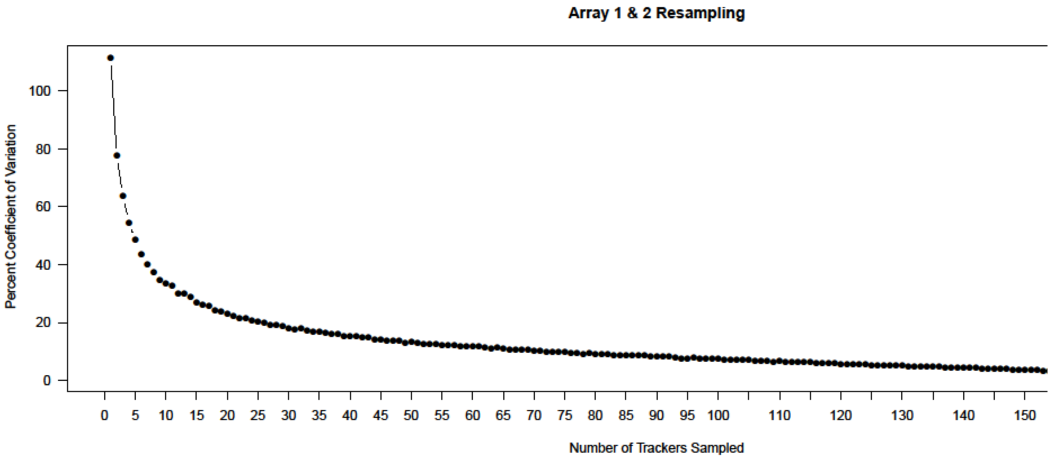

Figure 14. **Coefficient of Variation in Fatality Estimate Attributable to Sampling Variation for All Sample Sizes, Arrays 1 and 2 Combined**

Section 4.0 Discussion

4.1 Carcass-removal Rates

Almost half of placed carcasses were removed completely by scavengers or left insufficient evidence to be documented as a fatality during standardized carcass surveys. More than a third of these carcasses were removed within 7 days of placement, and would not have been detected during weekly fatality searches. The remaining carcasses persisted longer than the search interval, or were scavenged but left sufficient evidence to be considered a fatality by searchers. Only two carcasses left evidence insufficient to be considered a fatality, implying that if a carcass is scavenged in place, its remains will likely be detected during searches. A logical extension of this finding is that the creation of a feather spot when a bird is preyed upon by a raptor or mammalian predator is likely to occur at least as often as the creation of a feather spot during a scavenging event and feather spots created by depredated birds are likely to persist and be detected during searches at rates equal to feather spots created from scavenged carcasses.

The mean time to scavenging was 3.3 days, which is comparable to the mean times identified by carcass-removal studies at other sites. For example, Derby et al. (2007) found an average removal time of 5.1 days for small carcasses, and Smallwood et al. (2010) found an average removal time of 4.45 days for all carcass types. We found that the initial rate of scavenging was very rapid, followed by an exponential decrease; this pattern mirrors the findings of other studies. For example, Ponce et al. (2010) found that 32% of all carcasses were gone by the second day, and 52% of all carcasses were gone within a week. Our study's scavenging times may be somewhat shorter because we avoided scavenger swamping and used cameras. Wagner et al. (1983), Ponce et al. (2010), and Derby et al. (2007) likely overloaded the capacity of local scavengers to effectively dispose of placed carcasses (Smallwood 2010), whereas we placed smaller numbers of carcasses for removal trials. Our use of cameras allowed us to more accurately pinpoint the time of scavenging, whereas other studies (e.g., Derby et al. 2007 and Ponce et al. 2010) were limited by personnel availability; carcasses were often checked only weekly, rather than daily.

Our finding that the majority of small carcasses were removed within 7 days without leaving trace evidence suggests that the majority of small carcasses deposited on the site would be removed with no trace in between our weekly search intervals. Only rarely in our study did small-bodied carcasses leave remains behind after they were scavenged. Also, we found that large carcasses were more likely to leave evidence behind, and are therefore more likely to be detected during routine weekly searches.

The two most common scavengers, ravens and San Joaquin kit foxes, nest or den on the Project site, and coyotes (*Canis latrans*) regularly visit the site. In contrast, turkey vultures (*Cathartes aura*) are rarely seen on site and scavenged only one carcass. Although two other potential scavengers, American badgers (*Taxidea taxus*) and California ground squirrels (*Otospermophilus beecheyi*), occur on site, we did not document them at any of the carcasses that we placed. Likewise, Smallwood et al. (2010) documented red-tailed hawks scavenging carcasses, but we did not record any instances of scavenging by raptors, other than a turkey vulture, or owls in our study.

Although we did not place equal numbers of carcasses during the different seasons, our results do suggest that the time to scavenging was longest in winter and shortest in fall. This is a well-documented trend in carcass-removal trials (e.g., Prosser et al. 2008 and Smallwood et al. 2010). Many of the carcasses placed in winter froze at night, which may have made them less palatable to scavengers, or more difficult to detect by smell. In fall, there is less food available for scavengers because many of the nesting birds have left the area and insects such as grasshoppers are less common. This drop in food availability likely explains the shorter time to scavenging that we observed during this period.

Carcasses placed in the control plots were scavenged more quickly than carcasses placed in the solar arrays or along the Gen-tie Line. Carcasses were likely easier for scavengers to spot visually in the control plots, because there were lower levels of structural and vegetative cover on the control plots than along the Gen-tie Line and in the solar arrays.

Using remote cameras for the carcass-removal trials allowed a more accurate determination of carcass-removal time, reduced personnel time, and helped to document the scavenger species involved in carcass removals. In several instances, ravens removed carcasses within 15 minutes of placement. We could not have documented these quick removal rates without the use of the remote cameras. When cameras malfunctioned or failed to record scavenging, they were still able to narrow the time frame during which the carcass was removed, and so still yielded an advantage over daily or weekly checks by field personnel.

Among the scavenger species documented, ravens, in particular, are known for their high level of intelligence (Emery 2006). It is possible that ravens may have noticed the camera traps, and thus been alerted to the presence of new carcasses. However, Smallwood et al. (2010) explored this possibility by setting out camera traps with decoy carcasses, and found that none of the decoy carcasses were investigated by any scavenger species.

4.2 Searcher-efficiency Rates

Our overall searcher-efficiency rate of 53% is comparable to the results of searcher-efficiency trials conducted at wind energy facilities, where rates have ranged from 32% to 67% (Nicholson et al. 2005; Derby et al. 2007; Leslie et al. 2012; Johnston et al. 2013; Martin et al. 2013).

Although we were not able to make statistical inferences about the influence of season on searcher efficiency, there may be seasonal effects. For example, natural and artificial precipitation events (the solar panels are washed once a year) and the run off of condensed moisture, create patches of grass along the driplines of panels; vegetation changes in color from green to golden-brown and could either blend with or create a sharp contrast with the color of a fatality; and mean daily temperatures (e.g., extreme heat) could affect not only plant growth, but searchers' effectiveness. We observed a significant decrease in our detection rate between winter and spring, likely because in spring the high annual vegetation obscured planted carcasses.

Searcher efficiency in the surveyed rows of the arrays was slightly higher than in unsurveyed rows, as expected given that visibility is often reduced in adjacent tracker rows in the morning and the evening, when the solar panels are tilted the most.

Along the overhead lines, we found that searchers were more efficient at detecting fatality plants in easy visibility areas compared to moderate visibility areas. In many of the arrays and along the MVOH Line, construction-related activities disturbed the ground below the lines and along fence lines; however, vegetation height and density increased with increasing distance from array edges and overhead lines, resulting in reduced fatality detectability. Therefore, the ease of finding fatalities below powerlines and along fences may be magnified by the combined effects of the short distance from the searchers' paths to the fatalities and the relatively lower vegetation.

We found that the opposite was true in the arrays, where detectability was 8% higher in moderate visibility areas than in easy visibility areas. Many searchers focus their attention on the rows of clumped vegetation on either side of a searched row, where vegetation height and density is greater than in the middle of the row. (The vegetation is low to absent in the middle of rows because of continuous foot traffic and conditions that are drier than underneath the panels). This searcher behavior could explain the higher rate of detections in areas characterized as having moderate visibility.

Overall detection rates, explained by type of carcass planted, indicate that carcasses were somewhat easier to find than feather spots as a group, but that the detection of large or small carcasses differed by only 2%, in sharp contrast to a 38% difference in detectability between small and large feather spots. Understandably, feather spots are more detectable when more feathers are scattered over a larger area.

4.3 Weekly Fatality Searches

Causes of death were often difficult or impossible to determine from feather spots and carcasses found in the arrays. In a few cases, carcasses were found with no apparent injuries; in other cases, injuries (e.g., broken necks) indicated that a collision was the cause of death. Determining the cause of death from feather spots was even more difficult. We found feather spots on the ground near panels and on panels themselves. Fatalities may have occurred as a direct or indirect result of the presence of solar panels (e.g., a bird stunned by a collision with a panel can then be more easily predated), or they may indicate direct mammalian or avian predation. Solar panels likely contribute to direct and indirect causes of death for birds, but in many cases, it was not possible to determine cause of death. Because the ratio of feather spots to found carcasses was 20:3 during the reporting period, the inability to partition feather spots associated with collisions and feather spots stemming from predation has important implications regarding inferences that can be drawn from the fatality estimate.

In contrast to the uncertainty regarding causes of death within solar arrays, most fatalities found along the Gen-tie and MVOH Lines were located directly or nearly directly under these lines. This pattern suggests that many of these fatalities were caused by powerline collisions, and that the remains were indicative of scavenging, rather than predation. It is well documented that high-tension powerlines contribute to avian mortality, and especially to the mortality of larger birds such as waterfowl (Brown and Drewien 1995). However, very few large carcasses were detected during fatality searches of the Gen-tie and MVOH Lines. Instead, the majority of fatalities found were passerines, possibly reflecting the greater proportion of passerines that occur on the site. Nevertheless, these results suggest that the avian flight diverters installed on the Gen-tie Line may be successful in preventing collisions with larger birds, but are not effective at diverting smaller birds. Also, Gen-tie Line fatalities included migrant passerines not typically observed on the Project site or expected in the area. It seems likely that most of the migrant passerine fatalities are from nocturnally migrating birds, and the avian flight diverters on the Gen-tie lines appear to be ineffective in deterring these birds at night.

It is difficult to study how the mortality of large and small birds along the overhead lines compares with background mortality rates without having a linear control in the landscape. We know of no studies that control for background mortality rates along a linear corridor without an actual linear structure. Instead, most avian mortality studies of high-tension powerlines typically compare fatality rates of powerlines with or without avian flight-diverting structures (Brown et al. 1995; Janss and Ferrer 1998). Given that more passerine fatalities were documented along the lines than expected, and very few raptor fatalities were documented, a linear control would be useful in understanding how these fatality rates compare with background fatality rates for large and small avian groups in the Project area.

In addition to searching arrays and overhead lines, we conducted fatality searches along perimeter fences. Although these fences may represent a collision hazard for birds (Allen and Ramirez 1990), they also provide artificial hunting-perch habitat for predatory birds, such as loggerhead shrikes and kestrels (*Falco sparverius*) (Bohall-Wood 1987; Sheffield et al. 2001). Both species frequently occur in the arrays, and other studies suggest that they increase in abundance when artificial perches are introduced (Wolff et al. 1999; Yosef and Grubb 1999; Sheffield et al. 2001; Lynn et al. 2006). If perimeter array fences increase hunting opportunities for predatory birds, they may thereby contribute to fatality rates by creating feather spots from predation events along the fence lines and within the adjacent arrays. Flocks of birds, mostly passerines, were commonly seen roosting under the solar panels. Although we do not have data to quantitatively compare this activity in the arrays with roosting in surrounding Conservation Lands, it is plausible that the solar panels attract roosting birds, and thus increase the prey base for predatory birds, which have been documented hunting within the arrays (Refer to Photo 1: a 1-second photo sequence captured on remote camera).

Photo 1. **One-second photo sequence captured on remote camera depicting a red-tailed hawk foraging within a solar array.**

Horned larks and mourning doves commonly roost and nest under the solar panels, and the two species combined represent 63% of the total number of fatalities found within the arrays (Appendix D). When they were flushed, we observed these birds quickly navigating through the panels; in this high-clutter environment, some birds may fly into structural elements of the array. Species that fly in flocks seem to be at a greater risk of collision; it has been posited that birds flying in the rear of flocks are more likely to be unaware of upcoming obstacles (Janss 2000). Additionally, the relatively high densities of these species may provide greater opportunities for avian and mammalian predators to prey on these birds, resulting in feather spots that are recorded as fatalities.

In general, we estimated fatalities to be more abundant in the spring and less in the summer. This pattern is likely associated with the peak avian activity in the spring and the subsequent decline in activity in the summer, both documented through onsite avian point counts (HTH 2013). Because birds were more active on the Project site in spring, predation rates and collision rates are likely to be higher.

Accounting for the spatial organization of avian fatalities is an important aspect of designing surveys and making decisions about future sampling, monitoring, and avoidance and minimization strategies. The spatial organization of avian fatalities may be thought of in terms of the manner in which fatalities are connected with each other in space, and whether they exhibit apparent clumping, uniform or random distribution. This is a key aspect for future design of sampling and monitoring schemes for detecting avian fatalities, because if fatalities are clustered in space, then additional sampling to account for their clumping may be warranted. In this case, significant clumping of fatalities was not found.

4.4 Repeat Surveys

The fatality estimates we calculated from our 5-day and 1-day repeat surveys were all much higher than the estimates obtained from our weekly searches. This is because we extrapolated from the low amount of temporal and spatial coverage in these searches, which can cause high sample bias. The statistical methods we used in the Fatality Estimator are not appropriate for rare events, and caution is recommended when interpreting groups with a sample size lower than five. In all but one area (Array 2), there were fewer than 5 total fatalities found per survey area, included in the 5-day repeat search estimates. The inadequacy of the sample sizes for the repeat surveys (comprising usually only a few tracker units per array) is underscored by the power analysis, which, based on the year of empirical data collected from Arrays 1 and 2, suggests that each sample should comprise 30–35 tracker units (i.e., far more than were actually covered in the past year's repeat surveys).

4.4.1 5-day Repeat Surveys

Because detailed fatality searches have not been conducted previously at a large photovoltaic facility, we did not know at the start of our study whether the fatalities found would be predominately birds or bats. Similarly, there was little basis for projecting what the carcass scavenging rates might be, because scavenging rates often vary widely from location to location, as well as across years and seasons. In situations where carcasses of bats or other animals that are scavenged without leaving a trace occur more commonly, it is advantageous to conduct more intensive daily searches to increase the chances of detecting carcasses. However, after proceeding with the diverse elements of this study for more than a year, it became apparent that avian fatalities, particularly long-lasting feather spots, accounted for the bulk of the findings, and that most small and large carcasses and feather spots persisted for more than 7 days. These facts suggest that daily searches are not necessary at this site to accurately detect and quantify fatalities.

Owing to issues cited in the previous third quarterly report, the protocol for 5-day and regular weekly searchers working in overlapping areas changed at the beginning of June 2013. Therefore, during the fourth quarter, it was possible to determine the short-term permanence (within the 5-day period) of all feather spots and carcasses, whether they were detected during regular weekly searches or not. Although this quarter offered a relatively small sample size (7), data from weekly searches suggested that the relative permanence of feather spots was much greater than that of carcasses. This finding is supported by the overall ratio (20:3) of carcasses to feather spots found in the arrays during regular weekly searches

A general assumption of fatality searches is that searchers detect less than 100% of fatalities, owing to both environmental and individual constraints (e.g., vegetation height, visual obstacles such as support poles for the arrays, and worker fatigue) (Huso 2010). The results of both the 1-day and the 5-day repeat surveys support this premise, because more than half of the finds of repeat searches were missed by weekly searchers. Although the number of fatalities found by weekly searchers but missed by repeat searchers was not examined, we did record cases of weekly searchers finding fatalities that repeat searchers did not find, and it is likely that searcher misses go in both directions. The low rates of consistency between the findings of regular weekly searchers and repeat searchers also suggest that both random differences and differences that vary by individual searcher may affect search outcomes. For example, a taller searcher has a reduced field of vision into adjacent rows compared to a shorter searcher, and is unlikely to be able to fully compensate for this disadvantage, even with conscious efforts to look under the panels. Likewise, there are trade-offs based on where searchers focus their field of vision: if a searcher focuses on tufts of tall grass on the sides of array rows, he or she may overlook fatalities directly underfoot, and vice versa. Estimates of individual searcher efficiencies would provide useful information for model estimation of overall fatality rates. However, identifying individual efficiencies in a field team of our size (around 20 individuals) would require a prohibitively large number of searcher-efficiency trials (more than 1600 per year, excluding the explanatory variables of season and Project element).

Because of the high labor costs and time involved in 5-day repeat searches, the areas searched were very small, covering only 5% of most arrays and 5% of the fences. The small survey area covered and the infrequency of these searches (once a month at each site) resulted in a large sampling bias when extrapolating to entire Project elements. If fatality rates are low or not evenly distributed throughout the site, searching 5% of the area may be insufficient to accurately estimate fatalities, but increasing the search area is nevertheless very expensive and labor intensive. In addition, comparing two different methods for estimating fatalities is difficult when the true number of fatalities in not known, as is the case. Computer simulations may provide a method to test whether 5-day repeat surveys can accurately estimate fatalities on a site. However, the methods for estimating fatalities at wind energy facilities, which we adapted for this study, still represent a tested, reliable, and cost-effective way to estimate fatalities over a large site such as CVSR.

4.4.2 1-day Repeat Surveys

The 1-day repeat surveys were designed to increase understanding of searcher efficiency by providing an independent index of carcasses missed by the weekly searchers. However, 1-day repeat surveys did not provide a full measure of searcher efficiency because the efficiency of the 1-day repeat surveyor was not known. Although the searcher-efficiency trials involved dividing the number of found fatalities by a known number of fatality plants, 1-day repeat surveys counted found fatalities representing some proportion of an unknown total number of fatalities in the area. On this Project site, fatalities rates were not high enough to get an accurate sample from such small survey areas. We found very few fatalities in 1-day repeat surveys. As with the 5-day repeat surveys, the area covered by the 1-day repeat surveys was so small (5% of the array) that it was rare to encounter fatalities. Because our sample size from these searches was too small to make a reliable, independent estimate of searcher efficiency, data from these surveys were incorporated into regular weekly search data. Had fatality rates been higher, we may have been able to use these data in an independent detection probability analysis of searcher efficiency. Using data on the few fatalities actually detected, the results of such an analysis would have been inaccurate.

4.5 Fatality Estimator

This is the first study of its kind to be conducted on a photovoltaic solar project. In a review paper titled "Environmental impacts from the installation and operation of large-scale solar power plants," Turney and Fthenakis predicted that negative impacts on wildlife would occur because of fencing installed in wildlife corridors and changes in food availability and preying strategy, but posited that the number of direct fatalities caused by solar panels was likely to be low compared to other anthropogenic sources of fatalities (Turney and Fthenakis 2011). The only previous study of fatalities at a solar farm took place at a concentrating solar farm in 1983. The primary concern at that facility was singed feathers of birds flying through flux near a central tower generated by heliostats, or panels of reflective mirrors (Wagner et. al 1983). Fatalities in this report were reported over a time period, rather than over a given area, so we were unable to directly compare fatality rates calculated by our study to those previously reported. Likewise, Wagner et al. (1983) did not account for searcher-efficiency rates, and disregarded carcass-removal rates after a preliminary experiment. Failure to account for these issues can severely affect overall fatality estimates.

To give an initial estimate of fatality rates attributable to solar arrays beyond the background fatality rate, we estimated fatality rates for Array 1 using time periods beyond the time period this report covers. We estimated fatalities and confidence intervals for Array 1 based on a full year of data (20 September 2012 to 19 September 2013), and for the control plots for Array 1 and 2 from 15 November 2012 to 14 November 2013. We adjusted the control plot area estimate to cover an area the same size as Array 1 (66 trackers). We then subtracted the lower bound of the confidence interval for the control plot estimate from the Array 1 estimate to obtain an adjusted fatality estimate for Array 1 beyond the background fatality rate.

We estimated that 231 fatalities occurred over a full year in Array 1 (90% confidence intervals: 162, 382) based on 47 fatalities found, and 187 fatalities in the control plots (90% confidence intervals: 107, 367) based on 11 fatalities found. This resulted in an adjusted fatality range 90% confidence interval of 55-275 attributable to the array, or 0.83 to 4.167 fatalities per tracker per year This corresponds to a mean rate of 7.34, or (90% Confidence interval: 3.24 to 16.27 fatalities per MW per year, assuming 0.256MW per tracker).

There are several caveats to keep in mind when interpreting these estimates. As we reanalyze data with full years of surveys for the remaining arrays and control plots these estimates will likely change. Our sample area of control plots in this calculation was based on surveys of 22 tracker sized control plots, which we now know from resampling is a low sample size to calculate fatality rates from, especially for an area as large as the on-site conservation land at the CVSR Project. This is also a conservative adjustment, using only the lower bound of the confidence interval or minimum estimated number of background fatalities.

As we complete full years of surveys for the remaining arrays, this estimate will likely change. However, fatalities per megawatt of installed capacity are a useful metric to compare fatality rates across sites and methods of energy production (Arnett et al. 2008; Smallwood 2013). For example, at regional scales in North America, birds collide with wind turbines at similar rates (National Research Council 2007; Erickson et al. 2008; National Wind Coordinating Collaborative 2010; Smallwood 2013).

In terms of both vegetation and landscape features, the CVSR Project site is fairly homogeneous, particularly in and among arrays, mostly because of the geomorphology of the site but also partly due to the grading and ground disturbance that occurred during construction. Although during the two seasons in which we sampled all arrays, the overall estimates from each array varied by less than one fatality per tracker unit per season, fatality rates for different arrays may vary by season; therefore, a full year of sampling in all arrays is needed before it is known whether or not the number of fatalities is spatially even across arrays.

In contrast to the relatively homogeneous distribution of fatalities in the array areas, the difference between the Gen-tie Line fatalities and the MVOH Line fatalities is striking. The height and size of the Gen-tie and MVOH Lines are considerably different. Much of the linear area along the MVOH Line has been disturbed by construction-related activities, whereas nearly all of the grassland habitat along the Gen-tie Line is intact, and disturbance was limited to the tower pads and access roads to the pads. A natural wetland that provides many avian species with important resources also occurs along the Gen-tie Line. Furthermore, construction of the Gen-tie Line was completed in June 2012, whereas construction close to the MVOH Line was just coming to a close in fall 2013; therefore, noise and ground disturbance likely contributed to overall lower avian activity along the MVOH Line and consequently lower mortality rates.

At all Project elements, we found relatively few owls and diurnal raptors. However, the long-term effects on these birds of collision hazards such as solar arrays are unclear. For species that are K-strategists (i.e., larger animals that have relatively fewer offspring and live long), such as diurnal raptors and owls, even small numbers of fatalities may lead to long-term impacts. Other species that are r-strategists (i.e., smaller animals that have many offspring and are short-lived) may be better able to compensate for lowered population densities by increasing their clutch sizes and fledgling survival rates in response to an increased relative abundance of resources (Drewitt et al. 2008).

4.6 Conclusion and Recommendations

This annual fatality report offers insights into the under-studied effects of large solar photovoltaic installations on avian mortality. In the next annual fatality report, we will be able to report a site-wide estimate of fatalities for all seasons. Likewise, ongoing fatality searches, searcher-efficiency trials, and carcass-removal trials will help to increase the accuracy of our fatality estimates.

Based on our findings to date, we recommend the following:

- **Establish a Linear Control:** To better assess the fatality rates of passerines and raptors across the landscape, fatality searches along a linear control should be conducted, and fatality searches along the Gen-tie Line should continue for another year. Linear controls should be used to evaluate fatality rates along both the Gen-tie and MVOH Lines.

- **Measure Abundance of Passerines as Well as Raptors:** Point counts targeting both raptors and passerines should be conducted in arrays and along linear features, allowing comparisons to data on activity on the Conservation Lands. These counts and comparisons would indicate whether fatality rates are associated with species abundance. The current avian point counts are biased toward raptors and large birds.
- **Examine Ways to Partition Feathers Spots:** Because the ratio of feather spots to found carcasses was 20:3 during the reporting period, the inability to partition feather spots associated with collisions and feather spots stemming from predation has important implications regarding inferences that can be drawn from the fatality estimate. We are examining relationships within the existing data set in an attempt to quantify the relative contribution of predation events to the overall fatality estimates.

Discontinue Repeat Surveys: Given the low fatality rates on the site and the expense and labor involved in repeat surveys, 5-day and 1-day repeat surveys should be discontinued. We recommend focusing efforts on weekly fatality surveys. We recommend that daily searches generally not be conducted to obtain a fatality estimate because they are labor intensive and labor is generally offset by surveying smaller areas. Given the tradeoff between area covered and frequency of searches, it is better to conduct regular weekly searches of a larger proportion of the site. Daily searches would be most useful if they are necessary to answer specific research questions, for example linking fatalities to weather patterns or to test a deterrent method or some other form of mitigation where knowing more precise timing of fatalities is important, but data gathered for answering these questions should not be used to obtain a site-wide estimate.

We recommend avoiding multiple searches of the same area at different time intervals. If surveys are conducted at various search intervals on the same area to answer research questions, we recommend that the different search strategies be designed to avoid interfering with each other. For example, daily searchers would not collect fatalities so they will still be present for weekly searchers to find.

- **Modify Weekly Fatality Search Areas to Improve Sample Size:** We recommend discontinuing 100% searches of Arrays 1 and 2, reducing the coverage of these arrays to 20% based on the results of the subsampling error assessment (power analysis) of the first year of data. All other arrays should also be searched at the 20% level. Further, the smaller arrays close to each other should be combined so that a 20% sample comprises 30–35 tracker units.

- **Conduct Scent Dog Survey Trials:** Scent detection dogs could be used to increase searcher efficiency rates, particularly where grasses and forbs obscure fatalities. If scent dogs prove significantly better during bias trials, we recommend considering the use of scent dogs to conduct fatality searches, most likely in combination with human searchers, at least initially.

Appendix A. Avian Species Used in Searcher-efficiency Trials, September 2012 to September 2013

Species	Carcass Size
American coot (*Fulica americana*)	Large
American crow (*Corvus brachyrhynchos*)	Large
American kestrel (*Falco sparverius*)	Large
Band-tailed pigeon (*Patagioenas fasciata*)	Large
Barn owl (*Tyto alba*)	Large
Black-crowned night heron (*Nycticorax nycticorax*)	Large
Black-headed grosbeak (*Pheucticus melanocephalus*)	Small
Brewer's blackbird (*Euphagus cyanocephalus*)	Small
California towhee (*Melozone crissalis*)	Small
Cedar waxwing (*Bombycilla cedrorum*)	Small
Chestnut-backed chickadee (*Poecile rufescens*)	Small
Common raven (*Corvus corax*)	Large
Common yellowthroat (*Geothylpis trichas*)	Small
Cooper's hawk (*Accipiter cooperii*)	Large
Eurasian collared-dove (*Streptopelia decaocto*)	Large
European starling (*Sturnus vulgaris*)	Small
Greater roadrunner (*Geococcyx californianus*)	Large
Great horned owl (*Bubo virginianus*)	Large
Green heron (*Butorides virescens*)	Large
Horned lark (*Eremophila alpestris*)	Small
House finch (*Carpodacus mexicanus*)	Small
Lesser goldfinch (*Spinus psaltria*)	Small
Long-eared owl (*Asio otus*)	Large
Mourning dove (*Zenaida macroura*)	Large
Rock pigeon (*Columba livia*)	Large
Red-shouldered hawk (*Buteo lineatus*)	Large
Savannah sparrow (*Passerculus sandwichensis*)	Small
Swainson's thrush (*Catharus ustulatus*)	Small
Varied thrush (*Ixoreus naevius*)	Large
Warbling vireo (*Vireo gilvus*)	Small
Western meadowlark (*Sturnella neglecta*)	Small
Western scrub-jay (*Aphelocoma californica*)	Small
White-tailed kite (*Elanus leucurus*)	Large
Yellow-billed magpie (*Pica nuttalli*)	Large
Yellow warbler (*Setophaga petechia*)	Small

Appendix B. Avian Species Used in Carcass-removal Trials

Species	Carcass Size	Number Placed
Acorn woodpecker (*Melanerpes formicivorus*)	Small	1
American coot (*Fulica americana*)	Large	1
American crow (*Corvus brachyrhynchos*)	Large	7
American goldfinch (*Spinus tristis*)	Small	1
American kestrel (*Falco sparverius*)	Large	1
American robin (*Turdus migratorius*)	Large	2
Anna's hummingbird (*Calypte anna*)	Small	1
Band-tailed pigeon (*Patagioenas fasciata*)	Large	2
Barn owl (*Tyto alba*)	Large	4
Black turnstone (*Arenaria melanocephala*)	Large	1
Brewer's blackbird (*Euphagus cyanocephalus*)	Small	2
California gull (*Larus californicus*)	Large	1
California quail (*Callipepla californica*)	Large	1
California towhee (*Melozone crissalis*)	Small	2
Cerulean warbler (*Setophaga cerulean*)	Small	2
Cliff swallow (*Petrochelidon pyrrhonota)*	Small	1
Common raven (*Corvus corax*)	Large	2
Eurasian collared-dove (*Streptopelia decaocto*)	Large	6
European starling (*Sturnus vulgaris*)	Small	2
Great horned owl (*Bubo virginianus*)	Large	6
Greater roadrunner (*Geococcyx californianus*)	Large	1
Hermit thrush (*Catharus guttatus*)	Small	1
Horned grebe (*Podiceps auritus*)	Large	2
Horned lark (*Eremophila alpestris*)	Small	3
House finch (*Haemorhous mexicanus*)	Small	3
House sparrow (*Passer domesticus*)	Small	1
Lesser goldfinch (*Spinus psaltria*)	Small	2
Lincoln's sparrow (*Melospiza lincolnii*)	Small	1
Mourning dove (*Zenaida macroura*)	Large	4
Northern flicker (*Colaptes auratus*)	Large	1
Northern mockingbird (*Mimus polyglottos*)	Small	1
Peregrine falcon (*Falco peregrinus*)	Large	1
Pine siskin (*Spinus pinus*)	Small	1
Red-shouldered hawk (*Buteo lineatus*)	Large	4
Red-tailed hawk (*Buteo jamaicensis)*	Large	8
Red-winged blackbird (*Agelaius phoeniceus*)	Small	1
Rock dove/pigeon (*Columba livia*)	Large	4
Ruby-crowned kinglet (*Regulus calendulai*)	Small	1
Sharp-shinned hawk (*Accipiter striatus*)	Large	1

Species	Carcass Size	Number Placed
Western meadowlark (*Sturnella neglecta*)	Medium	1
Western screech-owl (*Megascops kennicottii*)	Medium	1
Western scrub-jay (*Aphelocoma californica*)	Medium	4
White-crowned sparrow (*Zonotrichia leucophrys*)	Small	2
White-tailed kite (*Elanus leucurus*)	Large	2
Yellow-rumped warbler (*Setophaga coronata*)	Small	2

Appendix C. Weekly Fatality Search Results: 16 August 2012 to 15 August 2013

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1	9/27/2012	Mourning dove	11S	233981	3915723	Feather spot.
Array 1	9/27/2012	Mourning dove	11S	233987	3915548	Feather spot. Suspected roosting/preening site.
Array 1	9/27/2012	Common raven	11S	233705	3915535	Feather spot.
Array 1	9/27/2012	Common raven	11S	234004	3915528	Feather spot.
Array 1	10/4/2012	Mourning dove	11S	233512	3915482	Feather spot. Suspected roosting/preening site.
Array 1	10/18/2012	Horned lark	11S	233542	3915733	Feather spot.
Array 1	10/18/2012	Burrowing owl	11S	233886	3915595	Feather spot.
Array 1	10/18/2012	Horned lark	11S	233579	3915738	Feather spot.
Array 1	10/18/2012	Horned lark	11S	233928	3915518	Feather spot.
Array 1	10/18/2012	Burrowing owl	11S	234000	3915471	Feather spot.
Array 1	10/25/2012	Horned lark	11S	233714	3915431	Feather spot.
Array 1	11/1/2012	Horned lark	11S	233442	3915776	Partial carcass with wings, legs, and bill. Bill impaled on tumbleweed. Cause of death possible predation by loggerhead shrike (LOSH).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1	11/1/2012	Horned lark	11S	234110	3915654	Feather spot.
Array 1	11/8/2012	Horned lark	11S	234103	3915641	Feather spot.
Array 1	11/8/2012	Mourning dove	11S	233950	3915518	Feather spot. Suspected roosting/preening site.
Array 1	11/8/2012	Western meadowlark	11S	233822	3915671	Breast feathers. Some skin attached.
Array 1	11/8/2012	Medium-sized bird	11S	233426	3915528	Medium-sized bird based on articulated knee or elbow and fibula/tibia.
Array 1	11/8/2012	Mourning dove	11S	233807	3915533	Feather spot (body feathers). Suspected roosting/preening site.
Array 1	11/8/2012	Short-eared owl	11S	233815	3915688	Feather spot. Feathers on panel. Cause of death possible panel strike.
Array 1	11/8/2012	Short-eared owl	11S	233891	3915349	Feather spot. Feathers, possible organs, whitewash, spot with dirt absent on panel. Cause of death possible panel strike.
Array 1	12/20/2012	Mourning dove	11S	233412	3915438	Feather spot (>50 body feathers). Feathers scattered over 2x2-m area.
Array 1	1/10/2013	House finch	11S	234021	3915462	Head impaled on tumbleweed. Cause of death possible predation by LOSH.
Array 1	1/10/2013	Horned lark	11S	234056	3915775	Feather spot (several primaries and body feathers). Smudge marks and four body feathers stuck to the bottom right corner of panel. Feathers found at the array edge. Cause of death likely a panel strike.

Area	Date	Species	UTM	Easting	Northing	Observation Details¹
Array 1	1/17/2013	Horned lark	11S	233952	3915772	Feather spot.
Array 1	1/17/2013	Western meadowlark	11S	233462	3915602	Feather spot (primaries, body, and contour feathers). Spread across 2x2-m area, likely wind-blown.
Array 1	1/31/2013	Horned lark	11S	233446	3915562	Feather spot (downy feathers).
Array 1	1/31/2013	House finch	11S	233740	3915310	Feather spot. Flesh on some feather tips.
Array 1	1/31/2013	Western meadowlark	11S	233930	3915672	Feather spot.
Array 1	1/31/2013	Mourning dove	11S	234119	3915660	Feather spot (13 body feathers). Suspected roosting/preening site.
Array 1	2/14/2013	Western meadowlark	11S	231009	3915719	Feather spot.
Array 1	3/21/2013	Horned lark	11S	234249	3915566	Feather spot (≥25 back and breast feathers). Several feathers found on the bare ground under the panels.
Array 1	3/28/2013	Horned lark	11S	234151	3915458	Feather spot. Near acoustic station near Array 1.
Array 1	4/18/2013	Horned lark	11S	234062	3915720	Feather spot (two secondaries with coverts attached, one secondary, and more than ten body feathers).
Array 1	5/9/2013	House finch	11S	234155	3915577	Feather spot (four primaries, ≥20 contour feathers).
Array 1	5/9/2013	Horned lark	11S	233866	3915476	Feather spot (~15 breast feathers in a clump).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1	5/16/2013	Horned lark	11S	233445	3915794	Feather spot (≥15 flight feathers and ≥50 body feathers).
Array 1	5/23/2013	House finch	11S	233794	3915504	Feather spot (~40 breast feathers).
Array 1	5/23/2013	Mourning dove	11S	233689	3915385	Feather spot (approximately ten body feathers tightly clumped).
Array 1	5/23/2013	Horned lark	11S	234007	3915780	Feather spot (seven tail feathers, ten primaries attached by tissue, ≥20 contour feathers, and four secondaries).
Array 1	5/30/2013	Horned lark	11S	233732	3915516	Feather spot. Wing parts and contour feathers. Nest with eggs ~30 cm away. Bird may have been predated.
Array 1	6/13/2013	American kestrel	11S	233506	3915434	Feather spot (five feathers, including three primaries).
Array 1	6/20/2013	American kestrel	11S	234249	3915575	Feather spot (one secondary, five wing coverts, and 15 breast feathers).
Array 1	7/18/2013	Mourning dove	11S	233427	3915713	Feather spot (~15 body feathers tightly clustered).
Array 1	7/18/2013	House finch	11S	233949	3915584	Feather spot (~15 body feathers).
Array 1	7/25/2013	Mourning dove	11S	233858	3915327	Feather spot (~25 contour feathers and coverts).
Array 1	7/25/2013	Great horned owl	11S	233865	3915329	Feather spot (11 contour feathers). Feathers worn and older than search interval.
Array 1	8/1/2013	House finch	11S	233704	3915471	Feather spot (~15 feathers of a wing). Feathers barely attached.
Array 1	8/1/2013	Common raven	11S	233570	3915547	Feather spot (~20 breast feathers attached in a clump to dried flesh).
Array 1	8/1/2013	Horned lark	11S	233908	3915420	Feather spot (12 secondaries and contour feathers). Feathers worn and older than search interval.
Array 1	8/8/2013	Mourning dove	11S	233431	3915425	Feather spot (17 contour feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1	8/8/2013	Common raven	11S	233602	3915623	Feather spot (ten primaries, 15 body feathers, and small amount of flesh dried to feathers).
Array 1	8/15/2013	Common raven	11S	233658	3915633	Partial carcass (wing).
Array 1 control plot	11/15/2012	Blackbird sp.	11S	234421	3915557	Feather spot.
Array 1 control plot	4/18/2013	Horned lark	11S	234835	3914331	Feather spot (two secondaries and three tail feathers).
Array 1 control plot	5/23/2013	Common raven	11S	234394	3915663	Feather spot (~20 contour feathers).
Array 1–2 fence	2/19/2013	Horned lark	11S	233393	3915496	Feather spot (≥15 body, one primary, and three secondary feathers).
Array 1–2 fence	3/5/2013	Mourning dove	11S	233616	3914432	Feather spot (≥20 body and breast feathers). Could be preening spot, but feathers were scattered in 1-m radius. Some feathers stuck together. Found 30 m north of fence point 17.
Array 1–2 fence	3/12/2013	Mourning dove	11S	233623	3914542	Feather spot (~50 breast feathers). Approx. 0.5 m east of fence.
Array 1–2 fence	5/7/2013	Unknown small bird	11S	234252	3914464	Feather spot (~20 body feathers, dark grey in color). Clearly rained upon.
Array 2 control plot	12/4/2012	Horned lark	11S	234801	3915162	Feather spot.
Array 2 control plot	2/5/2013	Tree swallow	11S	234303	3913572	Feather spot.
Array 2 control plot	2/5/2013	House finch	11S	234299	3913638	Whole carcass. No obvious injuries or signs of ill health.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 control plot	4/16/2013	Common raven	11S	233760	3914054	Feather spot (mixture of ~25 secondaries and contour feathers). Feathers scattered across 5 m.
Array 2 control plot	5/21/2013	Horned lark	11S	234756	3915202	Feather spot (15 flight feathers and ≥50 body feathers).
Array 2 control plot	7/23/2013	Horned lark	11S	233650	3914101	Feather spot (one tail feather and 14 contour feathers).
Array 2 North	12/4/2012	Western meadowlark	11S	234107	3915294	Feather spot. Wing (with some flesh) under panel at edge of tracker. Feather spot 4.6 m east, on top of panel (≥10 feathers stuck on panel with large smear marks).
Array 2 North	12/11/2012	Mourning dove	11S	234417	3915072	Feather spot. Body feathers and mourning dove (MODO) fecal droppings present. Suspected roosting/preening site.
Array 2 North	12/11/2012	Mourning dove	11S	233923	3915097	Feather spot. Body feathers and MODO fecal droppings present. Suspected roosting/preening site.
Array 2 North	12/11/2012	Horned lark	11S	234354	3915162	Feather spot.
Array 2 North	1/8/2013	Horned lark	11S	234492	3915122	Feather spot.
Array 2 North	1/8/2013	Horned lark	11S	234281	3915343	Feather spot (ten or more primaries and >50 downy feathers).
Array 2 North	1/8/2013	Horned lark	11S	234349	3915216	Whole carcass. Bird apparently died just prior to survey. Very good condition and weight. Possible head trauma. Seizure before death. No definitive evidence of panel strike. Cause of death potential panel strike.
Array 2 North	1/8/2013	Unknown small bird	11S	234013	3914931	Feather spot.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	1/8/2013	Mourning dove	11S	233775	3915006	Feather spot. Two feathers have blood on the ends.
Array 2 North	1/8/2013	Mourning dove	11S	233998	3915109	Feather spot.
Array 2 North	1/8/2013	Western meadowlark	11S	234474	3915002	Feather spot (clump of feathers).
Array 2 North	1/8/2013	California quail	11S	234458	3915015	Feather spot (clump of breast feathers).
Array 2 North	1/8/2013	American pipit	11S	233947	3915001	Whole carcass. No evidence of panel strike.
Array 2 North	1/15/2013	Mourning dove	11S	234116	3915029	Feather spot (primaries, secondaries, and body feathers).
Array 2 North	1/15/2013	Mourning dove	11S	234116	3915045	Feather spot (several downy and flight feathers). Found in same row as MODO feather spot from same day. Probably same fatality.
Array 2 North	1/15/2013	Common raven	11S	234369	3915286	Feather spot (contour feathers).
Array 2 North	1/15/2013	Western meadowlark	11S	234254	3915320	Feather spot (body feathers in small clump).
Array 2 North	1/15/2013	Common raven	11S	234384	3915309	Feather spot (body feathers).
Array 2 North	1/22/2013	Common raven	11S	234377	3915298	Feather spot (contour feathers). Potentially remnants from a previously collected common raven (CORA) fatality (1/15/13).
Array 2 North	1/22/2013	Mourning dove	11S	233835	3914945	Feather spot (clump of body feathers).
Array 2 North	1/22/2013	Mourning dove	11S	233902	3914945	Feather spot (downy feathers). Suspected preening site.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	1/22/2013	Mourning dove	11S	234359	3915322	Feather spot. Suspected preening site above cable tray.
Array 2 North	1/22/2013	Mourning dove	11S	234119	3915035	Feather spot (scattered feathers and one clump).
Array 2 North	1/22/2013	Horned lark	11S	234173	3915114	Feather spot.
Array 2 North	1/22/2013	California quail	11S	234393	3914986	Feather spot (clump of feathers).
Array 2 North	1/29/2013	Mourning dove	11S	233891	3914945	Feather spot (mostly breast feathers). Not under panel like most MODO preening areas.
Array 2 North	1/29/2013	Mourning dove	11S	234015	3914931	Feather spot (one clump of body feathers).
Array 2 North	1/29/2013	Mourning dove	11S	234365	3915193	Feather spot.
Array 2 North	1/29/2013	Mourning dove	11S	234367	3915164	Feather spot. Body feathers spread down row.
Array 2 North	2/5/2013	House finch	11S	234212	3915338	Whole carcass (broken neck). Cause of death potential panel strike.
Array 2 North	2/5/2013	Mourning dove	11S	233991	3914940	Feather spot. Skin attached to feathers.
Array 2 North	2/12/2013	Mourning dove	11S	234182	3915342	Feather spot (body and flight feathers). Some feathers with dried flesh attached at shaft base. Five body feathers stuck to solar panel, but no evidence of strike. Spread across entire tracker unit row.
Array 2 North	2/12/2013	Unknown small bird	11S	234198	3915347	Skeletal remains of wing and keel bones. Bones picked clean. Dried muscle fibers still attached but

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
						stringy.
Array 2 North	2/12/2013	Western meadowlark	11S	234409	3915384	Feather spot (~20 contour feathers).
Array 2 North	2/12/2013	House finch	11S	234464	3915452	Feather spot. Wing feather clumps. A few body and flight feathers on panel, but no evidence of panel strike. Many body feathers on ground under panel on outside face of tracker.
Array 2 North	2/12/2013	Mourning dove	11S	234386	3915162	Feather spot (~20 scattered downy feathers).
Array 2 North	2/12/2013	Mourning dove	11S	234386	3915157	Feather spot (two downy feathers on panel, two flight feathers on ground). No evidence of panel strike.
Array 2 North	2/12/2013	Mourning dove	11S	234260	3915252	Feather spot (>100 body and >10 flight feathers). Approximately 11 body feathers on panel, but no evidence of panel strike.
Array 2 North	2/19/2013	House finch	11S	233861	3914831	Feather spot (a few primaries and a few body feathers).
Array 2 North	2/19/2013	Mourning dove	11S	234396	3915436	Feather spot (≥50 feathers—ten or more secondaries and tertials and ≥40 body feathers). Feathers found stuck on panel. Possible panel strike or prey possibly eaten on panel.
Array 2 North	2/19/2013	Mourning dove	11S	234115	3915291	Feather spot (seven primaries with skin attached). Some feathers found stuck to panel. Possible panel strike or prey possibly eaten on panel.
Array 2 North	2/19/2013	Mourning dove	11S	234114	3915292	Feather spot (four or more secondaries, ≥15 body feathers, one tail feather, and one larger body feather). Absence of droppings and wide scatter of feathers indicate fatality and not preening station.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	2/19/2013	House finch	11S	234484	3915068	Feather spot (ten primaries and ≥50 body feathers). All feathers there—plucked.
Array 2 North	2/19/2013	Horned lark	11S	234442	3915295	Feather spot (≥15 body feathers and five or more primaries). Found directly under a panel.
Array 2 North	2/19/2013	House finch	11S	234164	3915141	Feather spot (≥30 body feathers).
Array 2 North	2/19/2013	House finch	11S	234261	3915153	Feather spot (ten primaries and ≥30 body feathers).
Array 2 North	2/26/2013	Western meadowlark	11S	234337	3915123	Feather spot (≥15 body feathers). All contour feathers. Isolated spot (not scattered).
Array 2 North	3/5/2013	Horned lark	11S	233901	3915118	Feather spot (five or more secondaries and ≥15 body feathers).
Array 2 North	3/5/2013	Horned lark	11S	234406	3915204	Whole carcass. Eyes gone but still fresh. Body warm but could be from intense sun. No visible signs of injury.
Array 2 North	3/5/2013	Horned lark	11S	234348	3915190	Feather spot (≥15 body feathers). White tips on body feathers.
Array 2 North	3/5/2013	Mourning dove	11S	234341	3915343	Feather spot (two flight feathers).
Array 2 North	3/12/2013	Mourning dove	11S	234227	3915000	Feather spot (≥50 body feathers and five or more flight feathers—mostly secondaries). Grey/white feathers. Spread over four rows. Some clumped feathers. Not a preening site.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	3/12/2013	Western meadowlark	11S	234250	3915070	Feather spot (one wing of ~20 primaries, five or more coverts, and yellow breast feathers).
Array 2 North	3/19/2013	House finch	11S	234341	3915005	Feather spot. Wings, foot, and feathers present (two wing partials; ≥20 primaries, secondaries, and coverts; and ≥50 body feathers). Bright red breast feathers present.
Array 2 North	3/26/2013	Horned lark	11S	234343	3915283	Whole carcass. Ants found in head and eye sockets. Found about 1 m from another horned lark (HOLA) fatality on same day. No signs of injury.
Array 2 North	3/26/2013	Horned lark	11S	234342	3915282	Feather spot. (partial wing, ten or more primaries and secondaries, five or more coverts, and ≥20 body feathers). Found about 1 m south of full HOLA carcass.
Array 2 North	4/2/2013	Horned lark	11S	234269	3914950	Feather spot. One clump of feathers on the cable tray (five primaries, six secondaries, two coverts, and one tail feather).
Array 2 North	4/2/2013	Horned lark	11S	234234	3915032	Feather spot. Clump of feathers (≥30 body feathers).
Array 2 North	4/2/2013	Horned lark	11S	234232	3915019	Feather spot (four primaries, eight secondaries, five tertials, and 12 contour feathers).
Array 2 North	4/16/2013	Horned lark	11S	234267	3915289	Whole carcass. No signs of injury.
Array 2 North	4/23/2013	Mourning dove	11S	234517	3915331	Feather spot (~15 primaries, 35 secondaries, ten tail feathers, 20 mantle feathers, and several hundred body feathers).
Array 2 North	4/30/2013	Mourning dove	11S	234268	3915260	Feather spot (one flight feather, ≥10 body feathers, and five body feathers in a clump).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	4/30/2013	Horned lark	11S	234215	3915114	Feather spot. Most feathers, including more than ten remiges, more than five retrices, and >75 contour feathers.
Array 2 North	4/30/2013	Horned lark	11S	234396	3914943	Feather spot (15 flight feathers, six tail feathers and 15 body feathers). Shafts of feathers broken. Possible juvenile, judging by sheaths. Probably not molting at this time of year. Feathers stuck to panel and cable tray. Possible panel strike or prey possibly eaten on panel.
Array 2 North	5/7/2013	Common raven	11S	234388	3915306	Feather spot (~30 body feathers). Some clumps of body feathers.
Array 2 North	5/7/2013	Horned lark	11S	234094	3915266	Feather spot (three tail feathers).
Array 2 North	5/14/2013	Horned lark	11S	234086	3915503	Whole carcass. Urea present on bird—most likely died minutes before discovered. Broken neck. Possible panel strike.
Array 2 North	5/21/2013	Horned lark	11S	234025	3915288	Feather spot (15 flight and five tail feathers). Found outside of tracker, off the side of the access road.
Array 2 North	5/28/2013	Horned lark	11S	234378	3915245	Whole carcass. Bird appeared emaciated, had excrement on cloaca.
Array 2 North	5/28/2013	Horned lark	11S	234072	3915037	Feather spot (one primary feather, ~40 body feathers, and five coverts).
Array 2 North	5/28/2013	Horned lark	11S	234343	3915250	Feather spot (six contour feathers and one tail feather). Two predated HOLA nests within 3–5 m of feathers.
Array 2 North	5/28/2013	Horned lark	11S	234073	3915038	Feather spot (~15 flight feathers, including some wing feathers still attached, and five body feathers).
Array 2 North	5/28/2013	House finch	11S	234020	3915176	Feather spot (feathers, wing, leg, and feathers with dried flesh).
Array 2 North	6/4/2013	House finch	11S	234338	3914975	Feather spot (11 body feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 North	6/4/2013	Common raven	11S	234338	3914976	Feather spot (~15 body feathers on road, close to panels).
Array 2 North	6/4/2013	House finch	11S	234315	3915314	Feather spot (seven flight feathers, ten body feathers, and five attached wing feathers).
Array 2 North	6/11/2013	Horned lark	11S	234520	3915047	Feather spot (two primaries and one contour feather). May not be a fatality because HOLAs were molting heavily at this time.
Array 2 North	6/11/2013	House finch	11S	234376	3915093	Feather spot (20 breast feathers, some clumped). Some feathers appeared to be plucked.
Array 2 North	6/11/2013	House finch	11S	234056	3915253	Feather spot (parts of wing, body feathers, and bone fragments).
Array 2 North	6/18/2013	Horned lark	11S	234193	3915167	Feather spot (partial wing and body feathers).
Array 2 North	6/25/2013	Mourning dove	11S	234211	3914933	Feather spot (two clumps, each with approximately eight contour feathers). Found on outside end of the tracker.
Array 2 North	6/25/2013	Horned lark	11S	234448	3915393	Feather spot (~15 body feathers, one contour feather, and one primary).
Array 2 North	7/23/2013	Horned lark	11S	233886	3914829	Feather spot (~50 body feathers and 20 flight feathers).
Array 2 North	7/30/2013	Mourning dove	11S	234289	3915258	Feather spot (several contour feathers).
Array 2 Serengeti	10/16/2012	Horned lark	11S	234520	3915036	Feather spot. Blood on some feathers.
Array 2 Serengeti	10/23/2012	Mourning dove	11S	234310	3914949	Feather spot (body feathers). Suspected roosting/preening site.
Array 2 Serengeti	10/23/2012	Mourning dove	11S	234344	3914998	Feather spot (body feathers). Suspected roosting/preening site.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 Serengeti	10/23/2012	Savannah sparrow	11S	234363	3915303	Whole carcass. No obvious injuries.
Array 2 Serengeti	10/30/2012	Mourning dove	11S	234231	3915068	Feather spot.
Array 2 Serengeti	10/30/2012	Mourning dove	11S	234526	3914949	Feather spot.
Array 2 Serengeti	11/13/2012	Western meadowlark	11S	234426	3915134	Feather spot.
Array 2 Serengeti	11/13/2012	Mourning dove	11S	234335	3915010	Feather spot.
Array 2 South	12/4/2012	Mourning dove	11S	233991	3914554	Feather spot (several flight feathers).
Array 2 South	12/4/2012	House finch	11S	234257	3914587	Decapitated carcass.
Array 2 South	12/4/2012	Mourning dove	11S	233680	3914437	Feather spot (≥20 body downy feathers and two flight feathers). Many MODO fecal droppings scattered in area. Suspected preening site.
Array 2 South	12/4/2012	Mourning dove	11S	233652	3914448	Feather spot (two feathers, possibly secondaries). Found at outer edge of tracker.
Array 2 South	12/4/2012	Unknown medium-sized bird	11S	233793	3914462	Feather spot (three feathers, including two primaries). Possible rock dove.
Array 2 South	12/11/2012	Western meadowlark	11S	233834	3914500	Feather spot (approximately ten secondaries).
Array 2 South	12/11/2012	Mourning dove	11S	233700	3914515	Feather spot (numerous downy feathers). Suspected preening site.
Array 2 South	12/18/2012	Mourning dove	11S	234132	3914957	Feather spot. In middle of row.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	1/8/2013	Mourning dove	11S	234116	3914561	Feather spot. Clump of feathers stuck to panel. Possible panel strike.
Array 2 South	1/8/2013	Mourning dove	11S	233790	3914470	Feather spot.
Array 2 South	1/8/2013	House finch	11S	234000	3914568	Feather spot. Carcass appears to have been plucked close to impact site. Impact smudge on the panel. Cause of death likely panel strike.
Array 2 South	1/8/2013	House finch	11S	234071	3914567	Feather spot.
Array 2 South	1/8/2013	Mourning dove	11S	233667	3914553	Feather spot (contour and flight feathers).
Array 2 South	1/8/2013	Mourning dove	11S	233888	3914516	Feather spot (approximately ten flight feathers).
Array 2 South	1/8/2013	Mourning dove	11S	233665	3914526	Feather spot (flight, body, and tail feathers). Spot widely scattered over two rows of panels.
Array 2 South	1/15/2013	Mourning dove	11S	234131	3914798	Feather spot (seven feathers: primaries, tail, and body feathers). Some primaries were a little muddy but it had not rained in the previous 24 hours.
Array 2 South	1/15/2013	House finch	11S	234345	3914896	Whole carcass. Odd growth above bill, possible avian pox. No apparent injury. Body still warm and limp, eyes not visible.
Array 2 South	1/15/2013	Mourning dove	11S	233664	3914388	Feather spot. Dried blood on ground. Many MODO roost here. Probably predated while roosting.
Array 2 South	1/22/2013	Mourning dove	11S	233669	3914469	Feather spot. Many (20–30) body feathers scattered throughout tracker, but remained clumped.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	1/22/2013	Mourning dove	11S	233642	3914421	Feather spot (four primaries and 20–30 body feathers).
Array 2 South	1/22/2013	House finch	11S	233654	3914575	Whole carcass. Ants on carcass. No broken vertebrae or broken wings found.
Array 2 South	1/22/2013	Mourning dove	11S	233849	3914553	Feather spot. Suspected roosting site.
Array 2 South	1/22/2013	Western meadowlark	11S	233683	3914427	Feather spot (>100 flight, body, and tail feathers). San Joaquin kit fox (SJKF) scat found on some feathers.
Array 2 South	1/22/2013	House finch	11S	234047	3914606	Partial carcass. Two wings, lower body, and feet found under cable tray and panel.
Array 2 South	1/22/2013	Mourning dove	11S	233654	3914575	Feather spot. Several distinct clumps of feathers.
Array 2 South	1/29/2013	Mourning dove	11S	234303	3914603	Feather spot (two flight feathers and spiral of breast feathers).
Array 2 South	1/29/2013	Mourning dove	11S	234022	3914568	Feather spot.
Array 2 South	2/5/2013	Western meadowlark	11S	233658	3914665	Feather spot. Single body feather and smudge marks on the lower left edge of panel. Large feather spot (body and flight feathers) scattered across tracker row. Some clumps of feathers with dried blood. Cause of death likely a panel strike.
Array 2 South	2/5/2013	House finch	11S	234200	3914856	Partial carcass and large feather spot (rump, two legs, and flight and body feathers). Found between trackers along road. Top portion of bill with orange tuft of feathers present. Breast feathers tinged with orange/red.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	2/12/2013	Mourning dove	11S	233891	3914457	Feather spot (15–20 downy and secondary feathers). No evidence of panel strike.
Array 2 South	2/19/2013	House finch	11S	234105	3914580	Feather spot (five or more primaries, a few secondaries, and ≥30 body feathers). At edge of tracker.
Array 2 South	3/5/2013	Horned lark	11S	234030	3914669	Whole carcass. Bill appears broken. Possible panel strike.
Array 2 South	3/5/2013	House finch	11S	234418	3914852	Feather spot (≥50 body feathers and ten flight feathers—mostly secondaries).
Array 2 South	3/19/2013	Mourning dove	11S	233662	3914435	Feather spot. Two primary feathers found under panel in area of abundant preening activity (fecal matter). Suspected preening site.
Array 2 South	4/2/2013	House finch	11S	234253	3914760	Feather spot (clump of >36 breast feathers, six primaries, and beak). Might have been plucked by avian predator.
Array 2 South	4/2/2013	Mourning dove	11S	233674	3914433	Feather spot (one secondary and 12 contour feathers). Suspected preening site.
Array 2 South	4/23/2013	Horned lark	11S	234030	3914728	Feather spot (~20 body feathers). Possible that more feathers blew away with high wind.
Array 2 South	4/23/2013	Mourning dove	11S	234214	3914706	Feather spot (20 contour feathers).
Array 2 South	4/30/2013	Horned lark	11S	233841	3914512	Feather spot (clump of ten body feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	4/30/2013	Brewer's blackbird	11S	234250	3914496	Feather spot (tip of left wing with flight feathers, coverts and alula, clump of tail feathers, body feathers with some skin, and one leg). More feathers two rows over (body feathers, flight feathers, and leg).
Array 2 South	4/30/2013	Mourning dove	11S	234465	3914864	Feather spot (≥15 body feathers in a few clumps with skin and dried intestine).
Array 2 South	4/30/2013	Common raven	11S	234104	3914491	Feather spot (~15 contour feathers).
Array 2 South	5/14/2013	House finch	11S	234310	3914591	Feather spot (one wing with flight feathers and coverts attached).
Array 2 South	5/14/2013	Unknown	11S	233830	3914497	Intestines of an unknown small animal.
Array 2 South	5/21/2013	Mourning dove	11S	234210	3914543	Feather spot (~20 feathers; three clumps with skin).
Array 2 South	5/21/2013	Horned lark	11S	234031	3914746	Feather spot (approximately six primaries and 35 body feathers).
Array 2 South	7/23/2013	Mourning dove	11S	234421	3914889	Feather spot (25 flight feathers).
Array 2 South	7/23/2013	Horned lark	11S	234439	3914890	Feather spot (five flight feathers).
Array 2 South	7/23/2013	Horned lark	11S	234196	3914623	Feather spot (two tail feathers and 15 body feathers).
Array 2 South	7/30/2013	Horned lark	11S	233649	3914409	Feather spot (~15 contour feathers).
Array 2 South	7/30/2013	Horned lark	11S	234366	3914575	Feather spot (three primaries, three tail feathers, two secondaries, two coverts, and ~35 contour feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 2 South	8/6/2013	House finch	11S	233972	3914601	Feather spot (~20 feathers, mostly primaries, and a few body feathers).
Array 2 South	8/13/2013	Horned lark	11S	234360	3914545	Feather spot (five flight feathers and ≥15 body feathers).
Array 4	1/9/2013	Mourning dove	11S	235596	3913032	Feather spot. Feathers in bunches, stuck together in clumps. Contour and wing feathers present, but no primaries or tail feathers.
Array 4	1/9/2013	Mourning dove	11S	235598	3913140	Feather spot. Contour and tail feathers only—no flight feathers present.
Array 4	1/16/2013	Mourning dove	11S	235591	3913465	Feather spot (≥100 body feathers). Feathers mainly in one central area, but some up to 4 m away.
Array 4	1/16/2013	House finch	11S	235672	3913330	Feather spot (14 flight feathers and numerous body feathers) and mandible.
Array 4	1/16/2013	Mourning dove	11S	235679	3913408	Feather spot. Feathers scattered. A second group of feathers, likely from the same bird but collected in a separate bag, found approximately 6 m north-northwest of this main feather group; both feather concentrations were fairly dispersed.
Array 4	1/16/2013	Mourning dove	11S	235610	3913174	Feather spot.
Array 4	1/16/2013	Mourning dove	11S	235588	3913193	Feather spot.
Array 4	1/16/2013	Mourning dove	11S	235616	3912749	Feather spot. Several hundred of feathers found.
Array 4	1/23/2013	Mourning dove	11S	235590	3913417	Feather spot. Only a few feathers, but one tail feather that was still mostly in the sheath; not a feather that would come from a live bird.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 4	1/23/2013	Mourning dove	11S	235624	3913517	Feather spot (>30 feathers).
Array 4	1/23/2013	Mourning dove	11S	235563	3913442	Older feather spot.
Array 4	1/23/2013	European starling	11S	235603	3912848	Feather spot (>50 body feathers).
Array 4	1/23/2013	Western meadowlark	11S	235761	3912701	Feather spot.
Array 4	2/13/2013	Western meadowlark	11S	235631	3912693	Feather spot at edge of row.
Array 4	2/13/2013	Mourning dove	11S	235767	3913293	Feather spot.
Array 4	2/13/2013	House finch	11S	235824	3913384	Feather spot (~15 body feathers).
Array 4	2/13/2013	Unknown small bird	11S	235737	3913347	Whole carcass. Fatality searcher informed of small dead bird on solar panel during weekly search. Bird was gone when searcher went to retrieve it 35 minutes later. Presumed to be removed by scavenger, potentially a CORA, which was seen in the area. Cause of death potential panel strike.
Array 4	4/24/2013	Horned lark	11S	235713	3913038	Feather spot (clump of ≥30 body feathers held together with dried skin).
Array 4	5/8/2013	House finch	11S	235724	3913524	Partial carcass (seven wing feathers still attached and one secondary).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 4	5/15/2013	Mourning dove	11S	235709	3913391	Feather spot (approximately ten primaries, six secondaries, and ≥30 wing and body feathers). Likely predated or scavenged by a mammal. Several feathers sheared off part way, as if bitten. Three clumps of feathers.
Array 4	6/12/2013	European starling	11S	235718	3912700	Feather spot (15 flight feathers).
Array 4	6/12/2013	House finch	11S	235767	3912695	Feather spot (23 flight feathers and ~50 contour feathers).
Array 4	6/19/2013	Yellow-rumped warbler	11S	235680	3912694	Feather spot (≥100 rump, contour, and wing covert feathers).
Array 4 control plot	4/17/2013	House finch	11S	236442	3912744	Feather spot (18 primaries, six other remiges, and ≥60 contour feathers).
Array 4 fence	2/13/2013	Mourning dove	11S	236303	3913354	Feather spot. Found outside of fence.
Array 5	1/16/2013	House finch	11S	236687	3913839[1]	Feather spot.
Array 5	2/6/2013	House finch	11S	236724	3913628	Feather spot.
Array 5	2/6/2013	Red-tailed hawk	11S	236683	3913857	Bones found (right leg and pelvis).
Array 5	3/27/2013	House finch	11S	236776	3913649	Feather spot (six primaries, two secondaries, and 20 breast feathers). Feathers sparsely spread across 3 m.

---

[1] Northing coordinate has been amended since the 2nd quarterly report was submitted, because this coordinate had been mislabeled.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 5	6/5/2013	House finch	11S	236779	3913577	Feather spot (three distinct clumps of feathers; ~40 breast and body feathers).
Array 8 Circuit 2	1/14/2013	Mourning dove	11S	233804	3912068	Feather spot.
Array 8 Circuit 2	1/21/2013	Mourning dove	11S	233641	3912191	Feather spot (four primaries and several body feathers).
Array 8 Circuit 2	1/21/2013	Mourning dove	11S	233630	3912302	Feather spot (several secondaries, coverts, and body feathers).
Array 8 Circuit 2	1/28/2013	Mourning dove	11S	234106	3911788	Feather spot (five primaries and >30 downy feathers).
Array 8 Circuit 2	1/28/2013	Mourning dove	11S	233543	3912244	Whole carcass. Found at preening site.
Array 8 Circuit 2	2/11/2013	Mourning dove	11S	233385	3912476	Feather spot (>20 body feathers, several flight feathers, and one clump of body feathers).
Array 8 Circuit 2	3/4/2013	House finch	11S	233416	3912277	Feather spot of partially intact whole wing, with five or more primary and secondary feathers each, and five or more body feathers.
Array 8 Circuit 2	4/15/2013	Western meadowlark	11S	233648	3912076	Partial carcass (wings and body, but no head). Could be red-tailed hawk (RTHA) kill. Two western kingbirds (WEKI) and one RTHA were observed earlier in day. RTHA was directly beside fence.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 8 Circuit 2	4/15/2013	Horned lark	11S	234052	3911694	Feather spot (one full wing, one partial wing, three breast feather clumps, and ≥50 loose body feathers). Feathers appear weathered.
Array 8 Circuit 2	7/17/2013	Great horned owl	11S	233957	3912424	Feather spot (two wings and >100 body feathers). Incidental fatality.[2]
Array 8 Circuit 2	7/22/2013	Horned lark	11S	234043	3911719	Feather spot (one primary and ~15 contour feathers).
Array 8 Circuit 2	8/5/2013	Horned lark	11S	233966	3911745	Feather spot (25–50 body feathers and several primaries). Found in charred substrate under panels and scattered throughout the tracker.
Array 8 Circuit 2	8/12/2013	Horned lark	11S	233976	3911740	Feather spot (~30 contour and flight feathers).
Array 8 control plot	3/4/2013	Mourning dove	11S	234418	3913321	Feather spot (two primaries together).
Array 1–2 fence	10/16/2012	Horned lark	11S	234527	3915080	Feathers and flesh hanging from fence, approximately 0.5 m off ground. One flight feather and flesh on ground right along fence.
Array 1–2 fence	10/30/2012	Mourning dove	11S	233399	3915720	Feather spot.
Array 1–2 fence	11/13/2012	Western meadowlark	11S	234418	3915494	Feather spot with beak and skull fragments.
Array 1–2 fence	12/4/2012	Mourning dove	11S	233852	3914441	Feather spot (≥20 body feathers).

---

[2] In the 4th quarterly report, this incidental fatality was reported as a long-eared owl on Figure 4, but was not included in the Appendix A summary of the weekly fatality search results. This species was later identified as a great horned owl.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Array 1–2 fence	12/11/2012	Mourning dove	11S	233793	3914373	Feather spot.
Array 1–2 fence	1/15/2013	Western meadowlark	11S	234383	3914539	Feather spot.
Array 1–2 fence	1/22/2013	Mourning dove	11S	233620	3914498	Feather spot. Two feather spots separated by 23 m, but feathers appear to be from same individual. Largely contour and down feathers, with a single primary found. Feathers spread on either side of the fenceline.
Gen-tie Line	8/29/2012	Burrowing owl	11S	234398	3916178	Feather spot at base of Tower 11. Feathers possibly from burrowing owl fatality previously found on 7/18/2012.
Gen-tie Line	8/29/2012	Horned lark	11S	234255	3916437	Feather spot scattered to the west of the tower 12.
Gen-tie Line	9/5/2012	Horned lark	11S	234266	3916692	Feather spot at base of Tower 13, directly below powerline.
Gen-tie Line	9/26/2012	Horned lark	11S	234527	3914444	Feather spot between Towers 3 and 4, directly below powerline.
Gen-tie Line	9/26/2012	Red-tailed hawk	11S	234302	3914086	Feathers with flesh attached, found between Towers 2 and 3, directly below powerline.
Gen-tie Line	10/3/2012	Horned lark	11S	234357	3917785	Feather spot at a feeding perch with droppings at the edge of the tamarisk wetland.
Gen-tie Line	10/3/2012	Long-eared owl	11S	234376	3917802	Feather spot in tamarisk wetland.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	10/10/2012	Medium-sized bird	11S	234303	3917740	Feather spot of unknown medium-sized species found between tamarisk wetland and Tower 17, directly below powerline.
Gen-tie Line	10/10/2012	Horned lark	11S	234274	3917044	Whole specimen between Towers 14 and 15. Directly below powerline, but no sign of injury. Cause of death possible line collision.
Gen-tie Line	10/17/2012	Horned lark	11S	234271	3916931	Feather spot near Tower 14. Directly below powerline.
Gen-tie Line	10/17/2012	Lincoln's sparrow	11S	234439	3916064	Whole carcass between Towers 10 and 11, directly below powerline. Cause of death possible line collision.

Gen-tie Line	10/17/2012	Savannah sparrow	11S	234573	3914618	Whole carcass between Towers 4 and 5, directly below powerline. Unidentified injury, but blood present on carcass. Cause of death possible line collision.
Gen-tie Line	10/17/2012	Mourning dove	11S	234358	3917786	Feather spot in tamarisk wetland. Found under perch where other feathers were found before.
Gen-tie Line	10/24/2012	Horned lark	11S	234203	3913888	Whole carcass between Towers 1 and 2, directly below powerline. Right wing broken. Cause of death possible line collision.
Gen-tie Line	10/24/2012	Savannah sparrow	11S	234391	3914203	Whole carcass between Towers 2 and 3, directly below powerline. No obvious injuries. Cause of death possible line collision.
Gen-tie Line	10/31/2012	American coot	11S	234470	3916002	Whole carcass between Towers 10 and 11, directly under powerline. Decapitated, but head found near body. Cause of death possible line collision.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	10/31/2012	Fox sparrow	11S	234592	3914983	Feather spot between Towers 5 and 6, directly under powerline.
Gen-tie Line	10/31/2012	Mourning dove	11S	234408	3917851	Feather spot in tamarisk wetland. Suspected roosting/preening site.
Gen-tie Line	10/31/2012	Northern flicker	11S	234304	3917708	Feather spot between tamarisk wetland and Tower 17, directly below powerline.
Gen-tie Line	11/14/2012	Western meadowlark	11S	234580	3914699	Whole carcass between Towers 4 and 5, directly below powerline. Head dislocated at the neck. Some neck feathers plucked. No other obvious injuries. Cause of death possible line collision.
Gen-tie Line	11/28/2012	Horned lark	11S	234255	3916696	Feather spot (≥20 downy feathers).
Gen-tie Line	12/11/2012	Common raven	11S	234610	3915356	Whole carcass. Electrical burns on feet. Found ~5 m from base of Tower 7. Cause of death electrocution.
Gen-tie Line	12/11/2012	Common raven	11S	234640	3915393	Whole carcass. Head scavenged. Scales peeled back on legs. Found ~15 m east of Tower 7. Cause of death electrocution.
Gen-tie Line	12/12/2012	Mourning dove	11S	234382	3917819	Feather spot (≥200 feathers—downy, body, and flight feathers).
Gen-tie Line	12/19/2012	Mourning dove	11S	234255	3916534	Feather spot (flight, tail, and body feathers).
Gen-tie Line	12/19/2012	Western meadowlark	11S	234426	3916094	Whole carcass. Neck intact. Wings not broken but bones exposed on upper left wing. No sign of external injuries. Fresh. Cause of death likely line collision.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	1/9/2013	Horned lark	11S	234374	3917774	Feather spot (body feathers and several secondaries and primaries).
Gen-tie Line	1/9/2013	Western meadowlark	11S	234256	3916730	Old feather spot along fence line east of main road.
Gen-tie Line	1/9/2013	Mourning dove	11S	234270	3916541	Feather spot (several tail and body feathers, and some secondaries and primaries).
Gen-tie Line	1/16/2013	Horned lark	11S	234355	3917785	Feather spot (breast feathers).
Gen-tie Line	1/16/2013	House finch	11S	234603	3915112	Feather spot (two primaries).
Gen-tie Line	1/23/2013	Common raven	11S	234291	3917304	Feather spot (primaries, secondaries, and a few contour feathers). Found about 4.6 m from the Gen-tie Line. Feathers appear sheared off (feather shaft cut at an angle). Feathers are weathered.
Gen-tie Line	1/23/2013	Mourning dove	11S	234357	3916221	Feather spot (tail, body, and primary feathers). Fresh MODO scat at feather spot. Found <3 m from Gen-tie Line.
Gen-tie Line	1/23/2013	Horned lark	11S	234381	3917831	Feather spot (body, tail, primary, and secondary feathers). Found in wetland area directly under Gen-tie Line.
Gen-tie Line	1/23/2013	Horned lark	11S	234390	3917811	Feather spot (body, tail, primary, and secondary feathers). Relatively fresh. Found in wetland area.
Gen-tie Line	1/23/2013	Loggerhead shrike	11S	234390	3917750	Feather spot (mostly primaries with some body feathers). Very old kill. Discovered buried under litter in wetland area while searcher was cleaning up a fresh feather spot from a HOLA.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	1/23/2013	Loggerhead shrike	11S	234390	3917813	Feather spot (two fresh primaries). Found in wetland area.
Gen-tie Line	1/23/2013	Horned lark	11S	234394	3917816	Mixed feather spot of fresh and old feathers, potentially indicating other HOLA kills at same location. Blood found on branch near spot. Found near three previously documented fatalities.
Gen-tie Line	1/23/2013	Horned lark	11S	234358	3917772	Feather spot (body, tail, and flight feathers). Found just outside wetland area, under shrub.
Gen-tie Line	1/30/2013	Horned lark	11S	234384	3917825	Feather spot (>20 flight feathers and >40 body feathers). Found in tamarisk wetland.
Gen-tie Line	1/30/2013	Horned lark	11S	234482	3917744	Feather spot. Found in tamarisk wetland.
Gen-tie Line	1/30/2013	House finch	11S	234575	3914595	Feather spot (>20 flight feathers and >50 body feathers).
Gen-tie Line	1/30/2013	Horned lark	11S	234569	3914573	Feather spot (>20 body feathers).
Gen-tie Line	1/30/2013	House finch	11S	234568	3914514	Feather spot.
Gen-tie Line	1/30/2013	Horned lark	11S	234482	3917744	Feather spot.
Gen-tie Line	1/30/2013	House finch	11S	234394	3917875	Feather spot.
Gen-tie Line	1/30/2013	House finch	11S	234572	3914523	Feather spot (many tail and wing feathers, some body feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	1/30/2013	House finch	11S	234556	3914504	Feather spot (>10 flight feathers and >20 body feathers).
Gen-tie Line	2/6/2013	Mourning dove	11S	234318	3914093	Feather spot. West of old farm house. Very likely a heavily used preening site.
Gen-tie Line	2/13/2013	Mourning dove	11S	234255	3916582	Feather spot (several hundred feathers—flight and body feathers). Possibly scavenged by SJKF—SJKF scat found at spot. Feathers found in two piles about 5 m apart. A "trail" of feathers connected the two piles. Scat from two animals (SJKF and pig or coyote) present.
Gen-tie Line	2/13/2013	Western meadowlark	11S	234413	3918059	Feathers spot. Feathers scattered across 10 m.
Gen-tie Line	2/20/2013	Savannah sparrow	11S	234285	3916896	Whole carcass. No visible signs of injury, but found directly under powerline. Cause of death possible line collision.
Gen-tie Line	3/20/2013	Horned lark	11S	234279	3917067	Feather spot (≥15 primaries and secondaries and ≥30 body feathers). Found directly under the powerline. SJKF scat present near spot.
Gen-tie Line	3/25/2013	Common yellowthroat	11S	234598	3915248	Whole carcass. Fresh blood on carcass. Tail broken. No other major injuries observed. Cause of death possible line collision.
Gen-tie Line	3/27/2013	Mourning dove	11S	234333	3917755	Feather spot (five or more secondaries and ten or more body feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	4/3/2013	Mourning dove	11S	234270	3916745	Feather spot (four coverts and ten or more contour feathers). Spread across 5-m diameter.
Gen-tie Line	4/17/2013	Horned lark	11S	234291	3917588	Feather spot (20 flight feathers and 50 body feathers). Found directly under the powerline.
Gen-tie Line	4/17/2013	Horned lark	11S	234599	3915172	Feather spot (~20 primaries). Found directly under the powerline.
Gen-tie Line	4/23/2013	Nashville warbler	11S	234143	3913787	Whole carcass. Tip of beak broken, indicating likely collision. Cause of death possible line collision.
Gen-tie Line	4/24/2013	Warbler sp.	11S	234279	3917306	Feather spot (20 flight feathers, ≥30 body/breast feathers—all downy). Found at fenceline parallel to road.
Gen-tie Line	5/1/2013	Horned lark	11S	234437	3914300	Feather spot (partial wing, ≥20 flight feathers, and ≥50 body feathers—mostly downy). Found directly under the powerline.
Gen-tie Line	5/8/2013	Warbling vireo	11S	234450	3914310	Whole carcass, very fresh. Possible broken neck. Found directly under powerline. Cause of death possible line collision.
Gen-tie Line	5/22/2013	MacGillivray's warbler	11S	234515	3918720	Feather spot (11 primaries and part of wing).
Gen-tie Line	5/22/2013	Mourning dove	11S	234513	3918735	Feather spot (~100 body feathers and one primary).
Gen-tie Line	5/22/2013	Warbler sp.	11S	234277	3917091	Feather spot (~30 contour feathers).
Gen-tie Line	5/22/2013	Yellow warbler	11S	234631	3915389	Feather spot (eight flight feathers and ~50 contour feathers).
Gen-tie Line	5/22/2013	Swainson's thrush	11S	234258	3916622	Feather spot (~25 flight and 50 contour feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-Tie Line	5/29/2013	Horned lark	11S	234275	3917246	Feather spot (~100 body and 12 flight feathers). Found directly under the powerline.
Gen-tie Line	5/29/2013	Yellow-rumped warbler	11S	234265	3917142	Feather spot (~100 body and 15 flight feathers).
Gen-tie Line	5/29/2013	Horned lark	11S	234265	3917142	Feather spot (12 body and six flight feathers). Pig scat present.
Gen-tie Line	5/29/2013	Warbler sp.	11S	234296	3917715	Feather spot (12 flight and 30 body feathers). Found directly under the powerline.
Gen-tie Line	5/29/2013	Horned lark	11S	234713	3915513	Feather spot (15 flight feathers, some attached by tissue, and ~100 body feathers).
Gen-tie Line	5/29/2013	Western meadowlark	11S	234618	3918793	Feather spot (15 primaries and secondaries and 15 body feathers). One clump of wing feathers attached by flesh.
Gen-tie Line	5/29/2013	Warbler sp.	11S	234717	3915511	Feather spot (25 flight and 50 body feathers, some held together by tissue).
Gen-tie Line	5/29/2013	Common raven	11S	234570	3914533	Feather spot (three flight and ten body feathers).
Gen-tie Line	5/29/2013	Horned lark	11S	234582	3914885	Feather spot (~50 body feathers).
Gen-tie Line	5/29/2013	Mourning dove	11S	234497	3918687	Feather spot (eight flight and ten body feathers).
Gen-tie Line	5/29/2013	Yellow warbler	11S	234423	3918671	Whole carcass. Found directly under the powerline.
Gen-tie Line	6/5/2013	Unknown small bird	11S	234586	3914810	Feather spot. A small number of body feathers connected by tissue at base of Tower 5.
Gen-tie Line	6/5/2013	Horned lark	11S	234257	3916588	Feather spot (four flight feathers, one tail feather, and 15 body feathers).
Gen-tie Line	6/5/2013	Yellow-rumped warbler	11S	234589	3914953	Feather spot (16 flight feathers and ~100 body feathers). Found directly under the powerline.
Gen-tie Line	6/5/2013	Warbler sp.	11S	234295	3917690	Feather spot (13 flight feathers and 30 contour feathers).

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
Gen-tie Line	6/5/2013	Warbler sp.	11S	234261	3916718	Feather spot (small clump of approximately ten body feathers stuck together with skin).
Gen-tie Line	6/5/2013	Unknown small bird	11S	234258	3916725	Feather spot (two tail feathers and one body feather). Found 5 m west of powerline.
Gen-tie Line	6/7/2013	Warbler sp.	11S	234615	3915267	Whole carcass. Found directly under the powerline.
Gen-tie Line	6/19/2013	Horned lark	11S	234643	3915468	Feather spot (~20 body feathers). Found ~90 m from the powerline. May not be associated with line.
Gen-tie Line	7/3/2013	Common yellowthroat	11S	234271	3917162	Feather spot (20 primaries and secondaries and ~70 body feathers). Nearly directly underneath the powerline.
Gen-tie Line	7/3/2013	Mourning dove	11S	234617	3918811	Feather spot (~20 primaries and secondaries, four tail feathers, and ~100 body feathers). Found scattered on hill southwest of Tower 22.
Gen-tie Line	7/31/2013	Mourning dove	11S	234279	3917054	Feather spot (numerous feathers from entire body).
Medium-voltage Overhead (MVOH) Line	1/30/2013	House finch	11S	234625	3913324	Decapitated carcass. Found outside fenced GKR site. Cause of death possible predation by LOSH.
MVOH Line	2/27/2013	Mourning dove	11S	236848	3913043	Feather spot (seven tail, a few primary, a few secondary, and ≥15 body feathers). Found ~250 m west of Array 6 edge, between second and third pole from start of MVOH Line west of Array 6. Multiple feathers found within a 2-m radius.
MVOH Line	3/13/2013	Barn owl	11S	238143	3912198	Feather spot (~12 wing feathers and two or three breast/body feathers). Mixed in and under Russian thistle piled against barbed wire.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
MVOH Line	4/1/2013	Common raven	11S	233898	3912970	Whole carcass. More than likely electrocuted on 3/28/2013, when a breaker blew out at the Substation. Electrocuted on/above coupler on the MVOH Line. May have arced across the lines.
MVOH Line	4/11/2013	Common raven	11S	233909	3912966	Whole carcass. Electrocuted at 8:30 AM at second tower to west, directly north of Array 8. Exit burn through neck, burn on belly. Singed feathers along left wing.
MVOH Line	4/17/2013	Horned lark	11S	234603	3913329	Feather spot (approximately nine primaries). Found under CORA nest on MVOH Line—nest is on powerline straight-away near Substation to the east.
MVOH Line	4/17/2013	Common raven	11S	234615	3913319	Feather spot (more than ten feathers). Difficult to collect because of wind. Located under CORA nest. Adults were lining the nest with white material. Found 100 m from the Operations and Maintenance facility.
MVOH Line	4/24/2013	House finch	11S	237860	3912838	Feather spot (ten contour and 15 flight feathers). Located directly under the powerline, ~20 m southwest of power pole.
MVOH Line	5/22/2013	European starling	11S	235550	3912671	Feather spot (part of right wing with primary and covert feathers).
MVOH Line	6/5/2013	Common raven	11S	234268	3913479	Feather spot (two flight feathers and one body feather). Found on road adjacent to tracker. Raven footprints present in the dust on the ground.
MVOH Line	6/5/2013	Common raven	11S	238155	3912221	Whole carcass. Dead juvenile seen hanging from nest, with pin and body feathers on ground.
MVOH Line	6/12/2013	European starling	11S	236683	3913043	Feather spot (approximately ten primaries and ten body feathers).
MVOH Line	6/19/2013	House sparrow	11S	233773	3915437	Feather spot (five flight and 15 contour feathers). Found directly under the powerline.

Area	Date	Species	UTM	Easting	Northing	Observation Details[1]
MVOH Line	7/10/2013	Western meadowlark	11S	235656	3912671	Feather spot (~100 breast, tail, and flight feathers).
MVOH Line	7/10/2013	House finch	11S	236680	3913043	Feather spot (six flight and tail feathers and ~30 body feathers).
MVOH Line	7/10/2013	Short-eared owl	11S	233895	3912971	Partial carcass (lower foot and small part of tibia).
MVOH Line	7/31/2013	Horned lark	11S	233839	3911689	Feather spot (~30 contour feathers). Found directly under the powerline.

Appendix D. Foraging Zone and Taxonomic Group of Species Observed Within Project Elements During Weekly Fatality Searches: 16 August 2012 to 15 August 2013

Species		**Foraging Zone**	**Taxonomic Group**	**Number Recorded**
Arrays				***238***
California Quail	*Callipepla californica*	terrestrial	avian resident	2
Red-tailed hawk	*Buteo jamaicensis*	terrestrial	raptor	1

Section 1. Introduction

Through adoption of Resolution #2011-119, the Board of Supervisors of the County of San Luis Obispo (County) approved the California Valley Solar Ranch Project (CVSR Project) Conditional Use Permit (DRC2008-00097) on 19 April 2011. The Conditional Use Permit is subject to the Conditions of Approval set forth in Exhibit 6 attached to the Resolution.

The Conditional Use Permit allows the Applicant (High Plains Ranch II, LLC, and any successor in interest for the life of the CVSR Project) to construct and operate a 250-megawatt (MW) photovoltaic solar power plant on an approximately 4685 acre (ac) site, located mostly south of State Route (SR) 58, about 4 miles east of Soda Lake Road, immediately north of the California Valley subdivision, in the Shandon-Carrizo planning area in San Luis Obispo County (CVSR site).

Condition of Approval (COA) #58 of the CVSR Project Conditional Use Permit requires an Avian Fatality Monitoring Plan (Plan) for the CVSR Project and a quarterly report detailing any project-related bird deaths or injuries detected during the monitoring study or at any other time. To satisfy COA #58 of the CVSR Project Conditional Use Permit, the Applicant has prepared this *Avian Fatality during Construction First Annual Report,* which documents the number of avian mortalities detected during project construction from September 2011 through September 2012.

Avian fatality monitoring was conducted consistent with the Plan as construction was completed within arrays and they became operational. The Plan provides for systematic assessment of avian fatalities and, when sufficient data is available, can be analyzed to determine statistically significant effects. Because per the Plan, avian fatality monitoring is initiated in each array block as it becomes operational, there is a period of time during construction when the sampled area is not large enough to meet the requirements of the analysis of significant effects. Because these methodologies differ significantly and the analyses cannot be combined, in this report and in quarterly reports going forward, fatalities during construction and results of monitoring during operations will be reported separately. The results of studies detailed in the Plan for post-construction monitoring in operational portions of the Project site will be covered in additional, separate *Avian Fatality Monitoring Quarterly* and *Annual Reports* initially timed to coincide with seasonal patterns of avian occurrence on the site and the initial implementation of the monitoring protocols. In the *Avian Fatality Monitoring Annual Report*, adequate data will have been collected to conduct the scientifically rigorous analysis required by the Plan and an associated assessment of potential adaptive management measures. This report will include relevant base line information as requested by the County.

Section 2. Monitoring Methodology

COA #58 requires monitoring the death and injury of birds associated with facility features such as feeder/distribution lines, solar panels, fences, and evaporation ponds. This Report documents avian mortality detected during construction activities from September 2011 through September 2012.

Monitoring of avian mortalities occurred during standard pre-activity surveys and construction monitoring. In addition, nesting deterrence for burrowing owls and other birds was conducted from 1 February – 31 August 2012. During monitoring of burrowing owl, one-way doors and searches for nests in impact and buffer areas, evidence of avian mortality was noted. Avian mortality data is collected within daily construction monitoring data sheets and includes date, location, and details of each observation.

Section 3. Results

From September 2011 through September 2012, 30 avian fatalities were detected during construction on the Project site (Table 1, Figure 1). These included 3 birds found in the giant kangaroo rat (GKR; Dipodomys ingens) relocation enclosures during pre-construction activities in October 2011, which were identified as 2 savannah sparrows (*Passerculus sandwichensis*) and 1 European starling (*Sturnus vulgaris*).

Also included in the avian fatalities are 5 birds reported to have been found dead in vertical piles by the County Environmental Monitor (not included in Table 1 or Figure 1 due to lack of detailed information) and 4 birds found dead in vertical piles and identified by H. T. Harvey & Associates biologists in early February 2012. These birds were identified as 3 horned larks (*Eremophila alpestris*), 5 mountain bluebirds (*Sialia currucoides*), and one American pipit (*Anthus rubescens*). Mortality was a result of an open vertical shaft in which birds were trapped.

Of the 30 avian fatalities detected, 14 were due to entrapment, 3 to vehicle strikes, 5 to predation, and 8 due to unknown causes.

Of the 30 avian fatalities detected, there was one American pipit, one burrowing owl (*Athene cunicularia*), 4 common ravens (*Corvus corax*), one European starling, 5 horned larks, 3 house finches (*Carpodacus mexicanus*), one lark sparrow (*Chondestes grammacus*), 5 mountain bluebirds, 5 savannah sparrows, one Townsend's warbler (*Dendroica townsendi*), 2 white-crowned sparrows (*Zonotrichia leucophrys*), and one species that was unidentifiable because only a portion of a wing was found.

Table 1. Avian Fatalities Detected during Construction from September 2011 through September 2012[1].

Date	Species	No.	Location	Observation Details
~10/24/2011	Savannah sparrow	1	Conservation Area	A dead savannah sparrow was found in GKR relocation enclosure during pre-construction activities. Cause of death was entrapment. UTM 11S 0235027 3912839.
~10/24/2011	Savannah sparrow	1	Conservation Area	A dead savannah sparrow was found in GKR relocation enclosure during pre-construction activities. Cause of death was entrapment. UTM 11S 0233561 3914287.
~10/24/2011	European starling	1	Conservation Area	A dead European starling was found in GKR relocation enclosure R7 during pre-construction activities. Cause of death was entrapment. UTM 11S 0233604 3914277.

---

[1] Does not include fatalities previously reported as detected during "fatality searches", which are part of the operational monitoring Plan and will be included in the *Avian Fatality Monitoring Annual Report.*

Date	Species	No.	Location	Observation Details
12/21/2011	Horned lark	1	Array 2	A horned lark was found dead on the ground among piles. Cause of death unknown. UTM 11S 0234127 3914884.
01/14/2012	White-crowned sparrow	1	Temporary Construction Facility	A white-crowned sparrow found dead in the grill of a truck was probably killed during travel to the site. Cause of death likely vehicle strike.
01/19/2012	Burrowing owl	1	Array 1	Burrowing owl feathers (15 feathers) from a scavenged individual were found scattered underneath a solar panel pallet in the array. Cause of death was likely predation.
02/02/2012	Horned lark	1	Array 2	A horned lark was found dead inside a vertical pile in the southern portion of the array. Cause of death was entrapment.
02/03/2012	Horned lark	1	Array 2	A horned lark was found dead inside driven vertical piles in Array 2. Cause of death was entrapment.
02/03/2012	Mountain bluebird	2	Array 2	Two mountain bluebirds were found dead inside vertical piles. Cause of death was entrapment.
02/09/2012	House finch	1	Array 1	A female house finch was found dead adjacent to the water storage tent near the first aid trailer in Array 1. Cause of death unknown.
02/10/2012	Common raven	1	Operations & Maintenance	A dead, flattened common raven was found with one wing clipped and the bill flattened and broken in half. The bird was weathered in appearance with exposed bone primarily around breast. Cause of death unknown.
02/15/2012	Savannah sparrow	1	Array 1	A savannah sparrow was found dead between two rows of panels, in the SE corner of the array with no evidence of injury. Cause of death unknown.
02/22/2012	Savannah sparrow	1	Main entrance	A savannah sparrow was found dead near the car wash. Cause of death may have been vehicle strike.
03/08/2012	Lark sparrow	1	SR 58	A lark sparrow was found dead on the north shoulder of SR 58, south of Gen-Tie #8. Cause of death was likely vehicle strike.
03/08/2012	Common raven	1	Array 4	Common raven feathers were found in the array. The feathers appeared to be old. Cause of death unknown.
03/23/2012	White-crowned sparrow	1	Gen-tie #15	A white-crowned sparrow was found dead about 20 ft south-southeast of Gen-tie #15. The bird had a puncture wound on back of head/nape with feathers plucked immediately around the wound and no other visible signs of injury. Cause of death was predation. UTM: 11S 0234289 3916912.

Date	Species	No.	Location	Observation Details
03/29/2012	House finch	1	Array 2	A house finch was found dead in a box of solar panels. The box lid had been warped by rain so it likely flew in and became trapped. Cause of death was entrapment. UTM: 11S 0234459 3915235.
04/18/2012	Horned lark	1	Array 2	A male horned lark found was found dead between panel rows in north-central Array 2 with no external injuries. Cause of death unknown. UTM 11S 0234199, 3915174.
04/19/2012	Savannah sparrow	1	Gen-tie #3 to Gen-tie #4	Savannah sparrow was found dead on the access road between Gen-tie #3 and #4. Cause of death unknown.
05/10/2012	Unidentifiable	1	Gen-tie #1 to Gen-tie #2	A portion of a bird wing was found between Gen-tie #1 and #2. Cause of death unknown, but likely predated and scavenged. UTM: 11S 0234213 3913902.
05/11/2012	Townsend's warbler	1	Gen-tie #2 to Gen-tie #3	A Townsend's warbler was found dead by a laborer. Cause of death unknown.
06/12/2012	House finch	1	Temp Tap (North of SR 58)	A male house finch was found dead inside an AC panel inside the Temp Tap building. Cause of death was entrapment. UTM 11S 234836, 3919053.
07/19/2012	Common raven	1	Black Bear Road	Juvenile common raven feathers were found below a telephone line, about 30 ft from the base of the telephone pole, ~15 ft west of Black Bear Road, mid-way between the intersections with Brady Trail and Belmont Trail. Cause of death was likely predation. UTM: 11S 0236482 3911499.
08/8/2012	Common raven	1	Array 4	A common raven was observed as a golden eagle prey item. A large feather pile, both wings and a leg were subsequently found. Cause of death was predation. UTM: 11S 236003 3914204.

GKR = giant kangaroo rat.

3.1 Avian Mortality in Piles

One of the first activities of constructing a solar array is to drive piles into the ground to support the solar panels. These vertical piles remain open and in place until a fitting that holds the solar panel is welded on top. Because these vertical piles are similar to vertical pipe mining claim markers, inside which a recent popular article reported occurrences of avian mortality, the piles were inspected. The inspection of approximately 200 vertical piles by the County Environmental Monitor detected dead birds in 5 of the piles. The birds were identified as one horned lark, 3 mountain bluebirds, and one American pipit. Subsequently, during pre-activity surveys and monitoring of construction activities in early February 2012, H. T. Harvey & Associates biologists detected dead birds in piles in Array 2. The birds were identified as 2 horned larks and 2 mountain bluebirds. Mortality was a result of an open vertical shaft in which birds were trapped.

3.2 Avian Mortality in Giant Kangaroo Rat Enclosures

During the monitoring of giant kangaroo rat relocation enclosures, a pre-construction mitigation activity, H. T. Harvey and Associates biologists detected several avian entrapments resulting in 3 avian mortalities within the enclosures; the carcasses included two savannah sparrows and one European starling. During the week of 23 October 2011, a Loggerhead Shrike (*Lanius ludovicianus*) was found in one of the giant kangaroo rat relocation enclosures and was released unharmed. Four savannah sparrows (*Passerculus sandwichensis*) were found in a second enclosure. Three were released unharmed, but one was dead. A dead savannah sparrow was found in a third enclosure. The carcass of a European starling was found in the artificial burrow chamber in relocation enclosure R7.

Avian Fatality During Construction - First Annual Report

Figure 1: Detected Avian Fatality Locations - September 2011 - September 2012

Section 4. Discussion/Conclusion

Of 30 detected avian fatalities during construction in the first year, 12 (40%) were the result of entrapment in vertical piles or giant kangaroo rat relocation enclosures; the cause of these mortalities was immediately resolved and no longer occurs (see below). Mortality of 2 house finches (6%) was also due to entrapment, one in construction materials and one in a structure under construction. Five fatalities (17%) were related to predation and are not likely construction-related. Three fatalities were related to vehicle strikes; these fatalities represent 10% of detected fatalities. However, one was on State Route 58 and could have resulted from any traveler on the highway and one was detected on the grill of a vehicle that had traveled to the site. The third fatality was on the access road near the entrance and could have been related to travel to or from the site or could have been related to a construction vehicle. For 8 fatalities (27%), the cause of the fatality is unknown.

4.1 Avian Mortality in Piles

To prevent avian mortality in vertical piles, the Applicant re-designed them as a solid C-channel pier, which does not present an open pipe. As a result, the redesigned C-channel piers, which were tested and implemented in August 2012, now permanently eliminate the possibility of bird entrainment from round vertical piles.

Prior to the C-channel redesign and following discovery that the round piles posed a risk of avian entrapment, to prevent continued mortality from entrapment within piles, the Applicant covered the exposed vertical piles with plastic caps until they were permanently closed or capped.

A letter describing the observed fatalities and additional preventative measures was provided to San Luis Obispo County, California Department of Fish and Wildlife (CDFW), and U.S. Fish and Wildlife Service on 10 February 2012. The caps were delivered on 10 February 2012, and all exposed vertical piles were capped on 11 February 2012.

Biological monitors on the Project continue to check any remaining round piles for the presence of the temporary plastic caps to further ensure that they remain in place until permanently capped. Caps may fall off the piles during wind and rain events. Those caps are replaced after the open piles are inspected for birds that may have become trapped.

4.2 Avian Mortality in Giant Kangaroo Rat Enclosures

Upon inspection of the giant kangaroo rat trapping and relocation enclosures, H. T .Harvey & Associates biologists found that birds likely entered the enclosures through small gaps between the nylon mesh that were stitched together with nylon ties. The top covers of the enclosures were originally constructed with heavy duty nylon mesh material (similar to standard construction environmental sensitive area fencing) with a mesh size of 0.5 to 1 inch; CDFW recommends a mesh size of 1.5 inches or less for avian enclosure material. Modifications to the relocation enclosures were implemented immediately after these observations. The modifications insured that future applications of avian exclosure material include no gaps larger than the mesh size to prevent the trapping of avian species. Additionally, the enclosure roofing material was altered to include a single-piece of shade cloth material, cut to fit the enclosure, resulting in fewer openings that can also be better secured. This material is expected to preclude smaller birds and avian predators from entering the enclosures and preclude giant kangaroo rats from jumping over the fence. A monitoring program has also been implemented to ensure that all enclosures are inspected daily for trapped birds.

During the monitoring of giant kangaroo rat relocation enclosures in subsequent months, H. T. Harvey and Associates biologists detected no trapped birds, indicating that modifications and repairs to the enclosure coverings have resolved the problem of birds entering the enclosure and becoming trapped.

4.3 Avian Mortality Due to Other Causes

Over the entire year, a total of 1670.77 ac was impacted by construction and only 12 fatalities were detected on the Project site during that period that could be attributed to construction activities. The causative factors have been addressed and no additional adaptive measures to minimize avian mortality are needed at this time.

Executive Summary

Project Overview

The California Valley Solar Ranch Project (CVSR Project) is a 250-megawatt solar photovoltaic energy facility located within an approximately 4685-acre site (Project site) in eastern San Luis Obispo County, California (Figure 1). The facility is owned and operated by High Plains Ranch II, LLC (HPR II). The Conditional Use Permit for the CVSR Project required that an Avian and Bat Protection Plan be prepared and implemented to monitor the impacts of the CVSR Project on birds and bats after construction. In compliance with the resultant Avian and Bat Protection Plan, avian and bat fatality searches were conducted from 6 June 2012 through 17 November 2014. This report represents the final avian and bat fatality report, and covers the monitoring results of searcher-efficiency trials, carcass-persistence trials, repeat fatality searches, regular weekly fatality searches, and incidental observations of fatalities from 16 August 2013 to 17 November 2014.

Methods

H. T. Harvey & Associates (HTH) biologists conducted weekly surveys in the following CVSR Project elements: Arrays 1, 2, 4, 5, 6, 7, 8, 9, 11, and in 20% of all associated perimeter fence areas, the Medium-voltage Overhead (MVOH) Line, the Generation-tie (Gen-tie) Line, and the Evaporation Pond. During the reporting period, all arrays were surveyed each week at 20% of their total area, with the exception of Arrays 1 and 2, which were surveyed with 100% coverage through the end of December 2013, at which time they too were surveyed at 20% of their total area. Additionally, to help identify the proportion of fatalities found that could be attributed to natural mortality rates, we surveyed control plots, located in Conservation Lands surrounding the CVSR Project site.

All fatalities were classified as either carcasses or feather spots. Feather spots consisted of groups of feathers composed of at least two or more primary flight feathers, five or more tail feathers, or 10 or more feathers of any type concentrated together in an area 1 square meter (m^2) or smaller (Smallwood 2007); feathers with significant skin or flesh, or with any bone attached, were considered fatality detections but were not necessarily considered feather spots.

In addition to performing weekly searches, HTH biologists conducted a series of repeat searches: 5-day repeats, in which biologists searched the same subset of a Project element for 5 consecutive days, and 1-day repeat searches, in which biologists searched a subset of an area that was searched 1 day previously by either 5-day repeat searchers or weekly searchers. The purpose of these repeat searches was to check the efficiency of searchers and evaluate the consistency of results; however, as reported herein, not all of the repeat searches proved necessary, and they were discontinued at the end of December 2013.

To estimate the rate of avian and bat fatalities occurring on the site, we used Huso's Fatality Estimator (2011). In formulating a fatality estimate, it was necessary to determine (1) the rate of scavenging that occurs on the site, and (2) how well searchers find different-size carcasses in different amounts of vegetation cover. These determinations were made by (1) planting fresh carcasses of birds of various sizes and placing camera traps on them to identify scavenger species and the exact time of carcass removal, and (2) planting both carcasses and feather spots of different sizes in different vegetation classes while regular weekly and repeat searches were taking place. Searcher-efficiency and carcass-removal rates were then used to adjust the annual count of fatalities to arrive at a site-wide fatality estimate.

We used background fatality rates estimated from searches of control plots within onsite Conservation Lands to adjust fatality rates within arrays. This enabled us to estimate mean background-adjusted fatality rates for the CVSR Project that represent fatalities that cannot be explained by background fatalities alone. This estimate was substantially less than the total unadjusted fatality rates within arrays. Our method used bootstrap resampling of observed data to estimate the mean and 90% confidence intervals for background-adjusted per-tracker unit fatality rates.

Results and Discussion

During the period of 16 August 2013 to 17 November 2014, a total of 453 avian fatalities, of 36 identified species and 5 unknown species groups, were detected. A total of 364 fatalities were found during standardized weekly searches. This number includes four clearance fatalities (fatalities found on the initial search of an area, which cannot be reliably aged or attributed to Project-related causes). A total of 54 fatalities were found during standardized 5-day and 1-day repeat searches. This number includes 18 clearance fatalities. A total of 35 fatalities were found incidentally. Two of the incidental fatalities were found in onsite Conservation Lands, and these, along with the four weekly clearance and 18 repeat clearance fatalities, were not used in any analyses in this report. That left an effective sample size of 429 fatalities that were used for analyses in this report.

Of the 429 fatalities found in Project elements and control plots during this reporting period, the cause of death for the majority (80.9%) could not be reliably discerned. Seventy-three (17.0%) were believed to have died as a result of a collision (65 with powerlines, 7 with solar panels, and 1 with a perimeter fence). Two deaths were believed to be caused by electrocution (0.5%). Six (1.4%) were believed to have been caused by predation, and one (0.2%) was believed to have been caused by disease.

Across Project elements, the majority (85.3%) of all fatalities were of resident species. The highest number of fatalities of migrants was found along the Gen-tie Line, where migratory species accounted for 21.5% of all fatalities. Seasonal variation was apparent in the pattern of fatalities found in both the arrays and along the Gen-tie Line. Fatalities found in the arrays peaked in the winter, whereas Gen-tie Line fatalities peaked in the late summer and fall.

For both carcass-persistence and searcher-efficiency trials, data were grouped over the entire postconstruction period to create a more robust sample size for the purposes of using the Fatality Estimator. One specimen was placed for each persistence or searcher efficiency trial. Between 15 October 2012 and 11 March 2014, we conducted carcass-persistence trials with 206 specimens. Eleven trial carcasses were excluded because the persistence data collected were insufficient (i.e., carcasses were collected by staff after the initial scavenging event), leaving an effective sample size of 195 carcasses. The carcass-persistence trials included 96 small carcasses and 99 large carcasses. Assuming conservatively that carcasses would not persist past the 6-week trial period, mean carcass persistence over the entire year was 9.3 days for small carcasses and 22.2 days for large carcasses.

In total, we planted 434 fatalities for searcher-efficiency trials. Three fatality plants were removed by scavengers, leaving an effective sample size of 431 (113 small and 98 large feather spots and 113 small and 107 large carcasses). Overall searcher efficiency was 50.8%, but varied from 57.3% to 44.5% in easy and moderate-visibility areas, respectively. Searcher efficiency also varied by size and fatality type: 72.9% of all large carcasses were found and 41.6% of all small carcasses were found, whereas 65.3% of all large feather spots were found and only 26.5% of all small feather spots were found.

During the period of 7 November 2013 to 6 November 2014 (the period used in the Fatality Estimator, representing one full year where weekly fatality searches occurred across all Project elements), there were an estimated 126 fatalities from known causes that occurred on the Project site (90% confidence interval: 106–155). There were not enough fatalities with known or suspected causes of death in the arrays to run a fatality estimate reflecting cause of death (N=2), but the estimate of fatalities per tracker in the arrays, for fatalities with unknown or natural causes of death, was 2.24 (90% confidence interval: 1.83–2.87). In the control plots, this estimate was 1.72 (90% confidence interval: 1.05–2.68).

For this same period, we estimated the mean background-adjusted per-tracker fatality rate to be 0.51 (90% confidence interval:-0.83-1.81) for one full year. The mean annual background-adjusted fatality estimate within arrays encompassing approximately 1176 acres at the CVSR project containing 1032 tracker units for the period of 7 November 2013 to 6 November 2014 was 526 fatalities (0.51 fatalities per tracker unit x 1032 tracker units).

Recommendations

During the course of this fatality monitoring study, we have identified areas where further research is needed to guide the design of future fatality monitoring studies at utility-scale solar facilities. The following recommendations outline research areas and measures that we believe are important.

- Background mortality should be assessed using a spatially balanced study employing control plots similar in size, layout, and overall total area to the developed project site.
- Focused research on the causes of feather spots and the average number of feather spots created from a single fatality should be considered.

- If site-wide fatality monitoring is deemed necessary, monitoring should start once the full project becomes operational and for at least one year. Fatality monitoring survey design, including spatial coverage requirements and survey frequency can be optimized after the collection of preliminary data.
- Intensive daily repeat fatality surveys are not necessary to conduct fatality estimates and are only recommended when required to link timing of fatalities to specific events (e.g., weather patterns or operational changes).
- Avian use studies should consider bird census techniques that are potentially more effective in documenting species richness and relative abundance of birds in project areas that will be covered by arrays, such as line transect methods.
- Projects incorporating high-tension powerlines should assess whether the project site is located in an important route for migratory songbirds.
- To assess fatalities along linear project features such as powerlines, study designs should incorporate linear controls, to provide background mortality rates for such features.
- To the extent practicable, powerlines should not be placed over wetland features, where large numbers of birds may roost and nest.
- We recommend that necropsies be performed on a subsample of carcasses to provide confirmation of the cause of the fatality.
- The use of scent dogs should be considered to increase the likelihood of detecting rare events and increase the accuracy and narrow the confidence level of fatality estimates, especially in areas with high density vegetation.
- Feather spots should be incorporated into bias-trial protocols to produce more robust fatality estimates and to provide more comparable industry-wide fatality estimates, especially for studies with longer search intervals.

Section 1.0 Introduction

On 19 April 2011, through adoption of Resolution #2011-119, the Board of Supervisors of San Luis Obispo County (the County) approved the California Valley Solar Ranch Project (CVSR Project) Conditional Use Permit (DRC 2008-00097). The CVSR Project is a 250-megawatt solar photovoltaic energy facility located within an approximately 4685-acre site (Project site) in eastern San Luis Obispo County, California (Figure 1). The facility is owned and operated by High Plains Ranch II, LLC (HPR II).

Before construction of the Project, there were concerns about the anticipated impacts that the Project might have on birds and bats. In particular, it was predicted that obligate waterbirds may mistake the panels for water and be attracted to the solar arrays; waterbirds are sometimes found in black-top parking lots or on roads, and some solar facilities have reported finding waterbird fatalities (Horvath et al. 2009; Grippo et al. 2014; Kagan et al. 2014). There was also concern that birds and bats could collide with panels (McCrary et al. 1986; Grippo et al. 2014). Although bird and bat mortality has been well documented at wind energy projects (Arnett et al. 2008; Baerwald and Barclay 2009), the level of CVSR's probable impacts was not certain. Therefore, H. T. Harvey & Associates (HTH) developed an Avian and Bat Protection Plan (ABPP) (HTH 2011) for the Project as required by the County as part of its Conditions of Approval (COAs), set forth in Exhibit 6 attached to the Resolution. As elements of the Project became operational, and continuing after the full completion of construction, HTH ecologists have implemented the *Avian and Bat Fatality Monitoring Plan for the California Valley Solar Ranch* (Fatality Monitoring Plan) (Appendix A in HTH 2011), conducting weekly fatality searches and additional searches to document impacts on birds and bats.

As required in COA #58, HTH, on behalf of HPR II, has submitted one annual report and eight quarterly reports detailing all Project-related bird or bat deaths or injuries detected during the monitoring study defined by the Fatality Monitoring Plan. This document represents the final fatality report for the Project. As required in the Fatality Monitoring Plan, this Final Postconstruction Fatality Report documents the results of postconstruction monitoring for 1 full year after completion of the Project. It summarizes the results of fatalities found since the end of the first annual reporting period (15 August 2013), integrating results from the most recent quarter of monitoring, and discusses the complete study period for the Project, where appropriate.

One of the main goals of the monitoring effort was to estimate the numbers of fatalities associated with different Project elements. In addition to performing regular weekly searches, we conducted searcher-efficiency trials to estimate the percentage of fatalities of different sizes found by searchers in both short and tall vegetation. To calculate the persistence of fatalities in the environment, we also conducted carcass-persistence trials. The values we derived from both types of trial were used in tandem with the results of the weekly searches to estimate ranges of fatalities associated with different Project elements. Additionally, to obtain an estimate of background mortality levels, we conducted controlled searches in control plots located on onsite Conservation Lands. We calculated levels of fatalities associated with various Project elements, using the Fatality Estimator (Huso 2011) to extrapolate from our survey data to the entire Project. The date range for all fatality estimates is based on one full year where weekly fatality searches occurred across all Project elements, from 7 November 2013 to 6 November 2014.

ABPP Final Postconstruction Fatality Report

Figure 1. Project Site with Gen-tie Line, MVOH Line, Evaporation Pond, Nine Arrays, and Control Plots

This Final Postconstruction Fatality Report is organized as follows:

- Section 2 describes our field and statistical methods.
- Section 3 presents the results of weekly and repeat fatality searches, describes trends and patterns in the monitoring results; and provides estimates of fatalities by Project element and cause of death.
- Section 4 draws comparisons between our results and the results of fatality searches conducted in other regions and industries.
- Section 5 lists recommendations for future studies.
- Section 6 lists the references cited in this report.
- Appendices A and B list avian species used in the searcher-efficiency and carcass-persistence trials.
- Appendix C presents data from weekly fatality searches for the period of 16 August 2013 to 17 November 2014.
- Appendices D and E present data from repeat searches for the period of 16 August 2013 to 31 December 2013 (after which repeat searches were discontinued).
- Appendix F lists fatalities that were incidentally observed in the period of 16 August 2013 to 17 November 2014.
- Appendix G includes errata for data reported in the first annual postconstruction fatality report (HTH 2014a); revisions were made to correct errors, erroneous omissions, or any other changes that were made to the dataset. Notes are included summarizing the reason for the change.

Section 2.0 Methods

This section presents the methods we used to conduct weekly and repeat fatality searches, collect data from incidental observations, and perform carcass-removal and searcher-efficiency trials. Project elements searched as part of this study were the Generation-tie (Gen-tie) Line; the Medium-voltage Overhead (MVOH) Line; Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11; the array perimeter fences; control plots; and the Evaporation Pond.

2.1 Field Methods

2.1.1 Weekly Fatality Searches

To estimate the total number of fatalities associated with different Project elements, we conducted a series of weekly fatality searches on different Project elements. Because the construction of different Project elements was completed at different times, fatality searches began at varying times of year, depending on the Project element searched (Table 1).

2.1.1.1 Field Search Methods

Weekly fatality searches were performed for the Gen-tie Line; MVOH Line; Evaporation Pond; Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11; and the associated control plots and fences for each array. The study design involved sampling 100% of the Gen-tie Line, MVOH Line, and Evaporation Pond. Twenty percent of Arrays 4, 5, 6, 7, 8, 9, and 11 were sampled, as was 20% of their respective fences. Arrays 1 and 2 and their associated fences were searched at 100% for the first year of fatality searches, after which (beginning in January 2014) they were searched at 20%, and four control plots were removed to reflect the decreased search effort in these areas. Each week, we selected random start locations for each Project element using a random number generator. Random selection was based on tower numbers (for the Gen-tie Line), line segment (for the MVOH Line), numbered array corners (for the solar arrays), and numbered fence corners (for the array perimeter fences).

A team of two biologists searched a 30-meter (m)-wide transect centered under the complete length of the Gen-tie Line. Because of the relatively shorter height of the MVOH Line, it was assumed that carcasses would have less potential to distribute over a wide area (HTH 2011); therefore, the transect area along the entire length of the MVOH Line was only 18 m wide. Each person searched half the transect width and half the tower or pole radial areas for both the Gen-tie and MVOH Lines. On the Gen-tie Line, each person searched a 15-m-wide transect for large birds and a 6-m-wide transect for small birds and bats. On the MVOH Line, each person searched a 9-m-wide transect for small and large birds.

Table 1. Fatality Search Commencement Dates by Project Element

Project Element	Date Fatality Searches Began
Gen-tie Line	6 June 2012
Array 1[1]	20 September 2012
Array 2 (Serengeti portion only)[2]	25 September 2012
Array 1 and 2 fence[1]	25 September 2012
Array 2 control plots	30 October 2012
Array 1 control plot	1 November 2012
Array 2 North (including Serengeti) and South[1, 2]	27 November 2012
Array 8 (20% sample)	7 January 2013
Array 4 (20% sample)	9 January 2013
Array 5 and fence (20% sample)	9 January 2013
Array 4 fence (20% sample)	16 January 2013
MVOH Line	30 January 2013
Array 8 control plots	4 February 2013
Array 4 control plots	6 February 2013
Array 8 fence (20% sample)	20 May 2013
Array 6 and fence (20% sample) and control plots	30 September 2013
Array 7 and fence (20% sample) and control plots	10 October 2013
Array 9 and fence (20% sample)	6 November 2013
Array 11 and fence (20% sample), and control plots	6 November 2013
Evaporation Pond	11 November 2013

Notes:
[1] Sampling reduced to 20% of total array area (starting 2 January and 7 January 2014 for Arrays 2 and 1, respectively).
[2] The Serengeti portion of Array 2 was searched separately only until 27 November 2012 (3 days).

In the arrays, biologists searched tracker units in teams of two. In each tracker unit, biologists walked into every other row of panels and visually scanned both the row walked and each adjacent row. To avoid crossing the drive arms of the tracker units, searchers turned around upon reaching the drive arm, and continued to scan the next row as they proceeded out of the row. Thus, although searchers walked only every other row, they visually scanned adjacent rows to ensure full coverage (Figure 2).

Control plots were randomly placed in adjacent onsite Conservation Lands to measure the level of background mortality. Control plots were designed specifically for comparing background fatality rates to fatality rates within arrays by making them equivalent to the size of a typical SunPower Oasis tracker unit (i.e., equivalent to 18 rows of solar panels, with 40 panels to a row), which measures approximately 79.9 m by 42.8 m (3416 m^2). Six aggregated tracker units comprise a typical tracker block that generates 1.5 megawatts. We used pin flags or wooden stakes to delineate mock panel trackers on the control plots, and searchers followed the same pattern and procedure used for searching the arrays. We did not establish control plots for the 20% sample of Arrays 5, 6, and 9 because the 20% search area for these arrays contained too few trackers to meet the control plot establishment guidelines set forth in the Fatality Monitoring Plan (Appendix A in HTH 2011; the guideline is one control plot [defined in the plan as having the same spatial scale as 2 aggregated tracker blocks, or 12 tracker units] for every 16 tracker blocks [96 tracker units] searched).

Twenty percent of the total fence length was surveyed by one biologist. Each week, the biologist walked the inside portion of the fence while scanning a 6-m-wide belt centered on the fence. In some cases, the fences were not completely built until after weekly searches had already commenced. In these instances, fences were included as part of the regular search routine only after they were completely installed.

Because searches were conducted only on designated days as a part of the search protocol, make-up searches were not conducted if the search day was missed because of inclement weather, holidays, or maintenance work. In estimating the total number of fatalities, the fatality model accounted for search intervals of different lengths due to missed searches (e.g., if a weekly search day was cancelled because of rain, the search effort would resume the following week, and for that search, the interval was 14 days, not 7 days).

ABPP Final Postconstruction Fatality Report
Figure 2: Fatality Search Pattern

2.1.1.2 Data Collection

We documented a fatality event each time a carcass or a feather spot was found. We considered a feather spot a fatality if it had at least two or more primary flight feathers, five or more tail feathers, or ten or more feathers of any type concentrated together in an area 1 square meter (m^2) or smaller (Smallwood 2007). We defined the number of feathers required to constitute a fatality using definitions employed in other fatality studies at wind farms (e.g., Gruver et al. 2009; Erickson 2009; Smallwood et al. 2010). Additionally, feather spots not meeting these requirements but containing flesh, blood, or bone were also considered fatalities.

During fatality searches, we occasionally encountered avian roost areas where signs of preening and molting were evident. Preening and molting spots typically have fewer feathers and are more spread out than feather spots associated with fatalities. Also, roosting areas rarely contain primary or secondary feathers, but are often dotted with droppings. In the solar arrays, we regularly observed flocks of mourning doves (*Zenaida macroura*) and horned larks (*Eremophila alpestris*) roosting. Mourning doves exhibit a complex molt strategy that can occur year-round and includes preformative, prealternate, and definitive prebasic molts (Otis et al. 2008). Likewise, horned lark adults and first-year birds undergo a definitive prebasic molt at the end of the breeding season (typically the end of July) (Beason 1995). Searchers used their biological knowledge to determine whether or not feathers from mourning doves, horned larks, or other species known to be in a molt period should be recorded as a fatality. No data were taken on molt or roost-spot feathers.

When a fatality was detected, we assigned the fatality a unique incident number and recorded data on the fatality and the substrate in which it was found. Incident numbers were written as follows: YYYYMMDD-##, consisting of the year, month, day, and a unique number assigned to each searcher. Each searcher recorded a unique set of numbers, so data can be traced back to individual searchers. To verify species identifications, we took photographs of each fatality and, when necessary, consulted Scott and McFarland's *Bird Feathers: A Guide to North American Species* (2010). We also consulted our feather reference collection, prepared from positively identified fatalities collected on the site over the course of Project monitoring. For each fatality, we recorded location (using Universal Transverse Mercator [UTM] coordinates), time found, taxon, four-letter alpha code, carcass condition, parts found, number and types of feathers, suspected cause of death, and estimated time since death. Whenever possible, we recorded information about the age and sex of the fatality, as well as scavenger type. Additionally, we gathered information on the size and spread of the feather spot and the surrounding substrate, vegetation height, and percent vegetation cover, as well as whether the fatality occurred in an array row walked by a searcher, or in a neighboring row (for fatalities found in the arrays). All carcasses and feather spots discovered by regular weekly searchers were removed.

The suspected cause of death was assessed for all fatalities and assigned to one of the following classes: collision, electrocution, predation, disease, or unknown. It was then further assigned a "Level of Certainty for Suspected Cause" category, as defined in the Migratory Bird Special Purpose Utility Salvage Permit (SPUT) for the Project (issued by the U.S. Fish and Wildlife Service [USFWS] on 10 March 2014 [permit number MB02733B-0]). Level of certainty was assigned as follows: Observed = 100%; Valid = >90%; Probable = >50%; Possible = <50%; or

Unknown/Not Applicable. To make the assessment, searchers examined all carcasses for signs of injury or illness, and assigned a cause of death using the following assumptions:

- Possible solar panel or powerline collision: If fatalities were found in arrays or under powerlines, we assigned collision as the cause of death with >90% certainty if carcasses had injuries consistent with an impact. We assigned collision as the cause of death with >50% certainty if feather spots or carcasses had no noticeable injuries but were found within 10 feet of powerlines. In arrays, we assigned collision as the cause of death with <50% certainty if feathers or flesh were stuck to solar panels, or if smudge marks or imprints, as from an impact, were observed on a panel.

- Electrocution: For fatalities near the MVOH Line, we assigned electrocution as the cause of death with >90% certainty if carcasses had visible injuries consistent with electrocution (e.g., singed feathers, burns on feet, or curled leg scales). Likewise, we assigned the same cause of death and level of certainty to a few fatalities based on circumstantial evidence (e.g., a breaker tripped during a recent rain event for an unknown reason, and a bird nesting on an overhead wire pole was found dead shortly afterward).

- Predation: We assigned predation as the cause of death with >90% certainty if birds were found impaled on tumbleweeds, fence lines or other structures. For decapitated carcasses found in any Project element, we assigned predation as the cause of death with <50% certainty. Fatalities found at sites regularly used by predators (e.g., at a plucking post), as indicated by old remains, were assumed to be predated with >50% certainty.

- Disease: We assigned this cause of death with >50% certainty if a carcass was emaciated or otherwise appeared unhealthy (e.g., if it had growths typical of avian pox).

- Unknown: Fatalities were assigned the designation of unknown cause of death when there was no compelling evidence to indicate how these fatalities occurred (e.g., carcasses had no obvious signs of injuries or illness, or body parts or entrails were present on solar panels but there were no visible imprints or smudge marks that allowed us to distinguish between predation and collision).

2.1.2 Repeat Searches

A series of repeat searches was designed to provide a verification of the results of weekly searches. Repeat searches were designed to create a shorter search interval that would allow carcasses with a short scavenging time to be more readily found and identified. Because repeat searches were intensive, they covered less area than the regular weekly searches. After the first annual report, it became apparent that avian fatalities, particularly long-lasting feather spots, accounted for the bulk of the findings. Likewise, the low number of trackers that were searched during each 5-day repeat search caused confidence intervals on these independent fatality estimates to be greatly inflated, compared to the estimates produced using weekly search data. For these reasons, the utility of repeat searches was greatly reduced, and the decision was made to cease all repeat searches (both 5-day and 1-day repeat searches) from 1 January 2014 onward. The methods used for the repeat searches, conducted before 1 January 2014, are summarized below.

2.1.2.1 5-Day Repeat Searches

Five-day repeats were conducted on all Project elements subject to regular weekly searches, with the exception of the Gen-tie Line, which was not included in the 5-day repeat searches because small birds and bats were assumed to be unlikely to strike high-tension powerlines. All other Project elements were subjected to 5-day repeat searches once every 4 weeks.

During each 5-day repeat search period, searchers covered a quarter of the total area covered during regular weekly searches (i.e., 25% of Arrays 1, 2, and the MVOH Line, and 5% of Arrays 4, 5, 6, 7, 8, 9, and 11), and the same areas were searched for 5 consecutive days. Because of the small size of the Evaporation Pond, searchers walked the entire perimeter of the pond during repeat searches. However, due to the large size of Array 2, 5-day repeat searches of Array 2 Serengeti were conducted separately from those of Array 2 North and South.

When possible, 5-day repeat searches were conducted in areas separate from regular weekly searches, to keep the search interval at a constant span of 7 days for all weekly search areas. In Arrays 1 and 2, however, overlapping search areas were unavoidable because weekly searches encompassed 100% of the arrays.

The first day of each 5-day repeat search was treated as a clearance search, and all fatalities found on the first day were removed from further analysis. Data for fatalities was collected in the same way as weekly search data, with the following exception: feather spots and scavenged carcasses were monitored throughout the search period, and notes were made regarding persistence. All remaining feather spots were collected on the fifth day of the 5-day repeats. For intact carcasses, cameras traps were placed near the carcasses to monitor persistence past the 5-day span of the repeat searches, with the intention of collecting additional data for carcass-persistence trials; however, due to technical issues, camera traps did not function properly during these trials and the data could not be incorporated.

2.1.2.2 1-Day Repeat Searches

One-day repeat searches covered a randomly selected block representing 25% of all elements (i.e., arrays, fences, and control plots) searched in the original weekly or 5-day repeat searches. Blocks were searched on the day following regular weekly searches, every other week (semimonthly), and after each 5-day repeat search, on either the last day of the 5-day search or 1 day after its completion.

2.1.3 Incidental Fatalities

Fatalities were sometimes found outside of regularly searched areas, both by CVSR Project personnel and HTH biologists. When this happened, fatality data were recorded and the fatality was collected in the same manner as if it were found during a weekly search. These fatalities could not be included in the site-wide fatality estimate, however, because the lack of a regular search interval made it impossible to accurately quantify the search effort for the area and the probability of finding the fatality. Nonetheless, all incidental fatalities are reported here, in the SPUT reports, and in reports for other Project salvage collection permits.

2.1.4 Carcass-persistence Trials

Carcasses decompose at rates that are influenced by environmental conditions, and carcasses and feather spots are also moved and dispersed by wind and scavengers. To calculate the number of fatalities that might be available for searchers to find in a given period, it is necessary to estimate the total persistence rates of carcasses. Scavenger species and density vary by region, so site-specific carcass-persistence trials must be conducted to accurately estimate fatality rates.

For our carcass-persistence trials, we acquired avian carcasses from the onsite fatality searches and a local wildlife rehabilitation center. We also collected them opportunistically (e.g., we collected road-killed birds) under State and federal salvage permits. Whenever possible, we used species that naturally occur on the site or in the surrounding area, and limited the handling of carcasses to reduce transfer of foreign scents. We categorized all carcasses into one of two sizes: small (≤100 grams [g]) and large (>100 g). For the purposes of the descriptive statistics and fatality estimates provided in this report, trial data from the first year and second year (between 15 October 2012 and 11 March 2014) are grouped together to provide a more robust fatality estimate. Of the 206 carcasses that we placed for carcass-persistence trials, 101 were large and 105 were small (Appendix B).

To avoid "scavenger swamping" (saturating our study area with more carcasses than resident scavengers are able to remove) (Smallwood et al. 2010), we limited the number of carcasses present in a search area at one time to four. We dropped carcasses from shoulder height and allowed them to fall naturally to the ground. We recorded each carcass location with a Global Positioning System (GPS) unit, and noted the direction and distance to the nearest tower (when carcasses were placed along the Gen-tie Line) or tracker number (when carcasses were placed in arrays). We placed Bushnell Trophy Cameras (Model 119436) within 1–1.5 m of the carcass on a t-post, facing north to avoid allowing sunlight to shine directly into the camera lens. We programmed cameras to take three date- and time-stamped photographs in quick succession after each trigger event; each camera had a 1-second refractory period between pictures.

We checked each carcass and the camera batteries and memory storage cards at least once per week, for up to 6 weeks or until the carcass was scavenged. We classified the carcass as "removed" if the carcass could not be located, or if there were fewer than ten feathers of any type or fewer than two primary feathers remaining. To classify feather spots, we used criteria similar to those used by the regular weekly searchers. Therefore, we classified the scavenging outcome as "not removed" if there were ten or more feathers of any type, two or more primary feathers, or any flesh or bone remaining. If the carcass was no longer in front of the camera and was not readily apparent, we searched the surrounding area using a spiral search pattern. We started the search at the camera's location and spiraled out to 30 m from the camera. If the carcass had been moved to a new location within the search area, but was intact, we repositioned the camera on the carcass in its new location.

During the first year of our study, we collected all remaining feathers and signs of the carcass after the initial scavenging event. However, after the first annual report, it became apparent that, because of the high proportion of feather spots found on site, it was necessary to estimate the full persistence time for carcasses, rather than the time to scavenging (in this report, use of the term *carcass persistence* rather than *carcass removal* reflects this broader focus). Therefore, in this document we report the time to scavenging as the time to the last scavenging event, and for scavenger species, we report the scavenger that resulted in the carcass's removal or conversion to a feather spot. In nine trials, carcasses were collected after the initial scavenging event, when partial or nearly whole carcasses remained behind. We exclude the results of these trials because they lack complete persistence data and we have no basis for estimating the time to the last scavenging event. Additionally, to accurately estimate total persistence, we conducted 30 feather spot persistence trials, in different vegetation heights, to determine appropriate adjustment factors to add to the persistence time of carcasses that were scavenged but left feather spots behind. We monitored each feather spot on a weekly basis for up to 4 weeks. To calculate the adjustment factor, we took the midpoint from the time between the last check when the feather spot was present and the first check when the feather spot was absent. We averaged these persistence times by vegetation class and added them to the total persistence time for all carcasses that left feather spots behind after scavenging.

For 28 of the carcasses that were removed and left no feather spot, the time of scavenging was not captured on camera. For the purpose of our descriptive statistics, we calculated the midpoint between the last photograph in which the carcass was present and the first photograph in which it was absent, and used that as the time of scavenging, to yield the total persistence time.

2.1.5 Searcher-efficiency Trials

Not all fatalities deposited in a search area are observed by searchers because detection is inherently imperfect, being influenced by topography, vegetation, fatality size and type, and the number of fatalities removed by scavengers (Thompson 1994). To determine how efficient searchers are at detecting fatalities, we conducted a series of searcher-efficiency trials, in which we placed trial fatalities (*fatality plants*) throughout the fatality search areas and calculated the average number of trial fatalities found by searchers.

For the purposes of the descriptive statistics and fatality estimates provided in this report, trials from the first year and second year are grouped together to provide a more robust fatality estimate. Therefore, we report on a total of 52 days of searcher-efficiency trials, starting 5 September 2012 and ending 31 July 2014, and representing the entire postconstruction study period.

We used both carcasses and feather spots in various amounts of vegetation cover throughout the year to characterize separate rates of searcher efficiency for fatality size (large or small), fatality type (carcass or feather spot), and visibility. Trial fatalities included specimens of common species found on the CVSR Project site and suitable proxy specimens salvaged from a local wildlife rehabilitation center (Appendix A). To avoid harming scavengers, euthanized specimens were not used for bias trials. In total, we planted 434 fatalities for searcher efficiency trials. Three fatality plants were removed by scavengers, leaving an effective sample size of 431 (113 small and 98 large feather spots, and 113 small and 107 large carcasses).

We assigned each species of carcass to one of two sizes (small or large) based on weight (i.e., small = ≤100 g; large = >100 g), as defined in *The Sibley Guide to Birds* (Sibley 2000). We also assigned a size to each feather spot based on spread of feathers. A small feather spot was defined as feathers from a small or large bird, scattered in a ≤20-square-centimeter (cm^2) area; a large feather spot was defined as feathers from a small or large bird scattered in an area >20 cm^2. In total, we classified all fatality plants into one of four size classes: (small feather spot, large feather spot, small carcass, or large carcass).

We originally categorized visibility into one of three classes: Easy, Moderate, or Difficult, based on a combination of vegetation height and percent vegetation cover (Table 2; Figure 3) within a 1-m^2 area surrounding each fatality plant. However, because the Difficult visibility class was rarely present (N=5), for all analyses, we lumped Moderate and Difficult visibility classes together in the High vegetation height category.

Table 2. Visibility Classifications Assigned to Categories of Vegetation Height and Percent Cover

Vegetation Height (Low <25 cm, Medium 25-50 cm, High >50)	Vegetation Cover (%)	Visibility Classification
Low	0–50	**Easy**
Low	50–100	**Moderate**
Medium	0–25	**Easy**
Medium	25–100	**Moderate**
High	0–50	**Moderate**
High	50–100	**Difficult**

In the field, we used a combination of haphazard and random, stratified sampling to determine the placement of each fatality plant. Haphazard sampling was incorporated to ensure that a representative number of trial fatalities were placed in all visibility classifications. We marked each fatality plant discreetly with tape or flagging so that searchers would know to report their findings as part of the controlled searcher-efficiency trial. We arrived approximately 1 hour in advance of the searchers so that we could set out fatality plants without alerting searchers that they were being tested. We recorded a GPS point for each fatality plant, and assigned it to a visibility group. Searchers contacted the efficiency-trial biologist as they discovered trial plants, and all plants were removed from the field once the fatality search was completed.

a) Easy Visibility

b) Moderate Visibility

Figure 3. **Photographic Examples of Easy (a) and Moderate (b) Visibility Classes for Feather Spots (Top Two Panels) and Carcasses (Bottom Two Panels), Based on Vegetation Height and Percent Cover**

2.2 Statistical Methods

Animals die at an unknown rate, which must be inferred from regular searches of a site. Secondly, fatalities persist for varying amounts of time and are imperfectly detected by searchers. For these reasons, it is often inappropriate to draw conclusions based on the raw number of fatalities in an open system. The need to accurately estimate fatalities given these variables has driven the development of several fatality estimation statistical methods (e.g., see Johnson et al. 2003; Smallwood 2007; and Huso 2011). All of these fatality estimation models are based around several common themes; in particular, all such models are designed to infer information about the total number of fatalities or total fatality "population" based on fatalities that are found. In an open system, the true total number of fatalities is unknown and cannot be determined, but fatality estimators use information based on average scavenging times and average searcher efficiency to form a number range (confidence interval) that likely contains the true number of total fatalities for a given site. The interval can be broadened or constrained based on the level of confidence desired. For this report, we use 90% confidence intervals for all fatality estimates. This means there is a 90% probability, based on our sample size that the true number of fatalities falls within our estimated range.

Because fatality estimates are based on the total number of fatalities found, there is an inherent bias when low numbers of fatalities are discovered. This is often referred to as *sampling bias*; it refers to the fact that small sample sizes may include outliers that are not representative of the wider population (in this case, the total number of fatalities that occur). As the number of fatalities found grows larger, the number, size, and species of fatalities should become more representative of the population, and fatality estimates become more accurate. Throughout this report, we urge caution in the interpretation of estimates based on small sample sizes; also, we did not calculate estimates based on data representing fewer than five fatalities.

As mentioned above, fatality estimation methods share a similar underlying premise. Generally, the fatality estimation formula for a given site may be written as:

$$F = C/rp,$$

where the number of fatalities, F, is the quotient of the number of carcasses found, C, over the product of carcasses left unscavenged, r, and the proportion that an observer sees, p (Huso 2011).

The inputs for r and p are estimated in subgroups of covariates that influence the detectability and persistence of each carcass, such as carcass size, vegetation height, and stage of decay or scavenging (i.e., feather spot versus carcass). Given the tendency for many fatality estimation models to underestimate site-wide fatalities, we chose to use a fatality estimator written by Huso (2011), which was shown to outperform previously developed models by more accurately accounting for imperfect detectability. This model, the Fatality Estimator, was developed to estimate fatalities primarily for wind energy projects; however, it can be applied to other types of sites, including powerlines and solar projects (Huso 2011). The Fatality Estimator uses the conceptual framework of fatalities, combined with bootstrapping from models of r and p, to calculate variances and confidence intervals for the estimate of total fatalities. (*Bootstrapping* is a statistical method used to create a distribution to assign measures of variance to estimates when the underlying distribution of data is either unknown or cannot be represented algebraically (Efron and Tibshirani 1986)—bootstrapping resamples the data, by taking a subsample of the entire data set several thousand times to create a distribution that may be used to infer information about the sample mean).

2.2.1 Estimating Carcass-persistence Rates

Measurements of carcass-persistence rates, r, typically include one or more censoring values. A *censoring value* is used in statistics when a value is only partially known. For example, if a carcass was checked on day 7 and was present, and was checked again on day 10, but was found to be missing, then the date of scavenging is unknown, and an interval censor would be used. Because we used camera traps, the majority of scavenging times were known precisely, and the data were not censored. However, when cameras failed to record the moment of scavenging, we applied interval censoring. Likewise, because feather spots were collected after scavenging events, a right censor was applied to trial carcasses that resulted in feather spots (right censors are typically used when the carcass or feather spot is collected prior to the end of the trial). Finally, owing to camera malfunctions, no photographs were taken of some carcasses prior to scavenging. In these cases, the carcasses and all evidence of the fatalities were removed before the first field observation. The time to scavenging and total persistence time for these carcasses was calculated as the midpoint from the time of placement to the time of the first field check, and a left censor was applied in the model.

There are four commonly used survival model distributions that can be used in the Fatality Estimator for a value of *r:* exponential, Weibull, loglogistic, and lognormal. These four distributions have different rates and shapes of decay curves that attempt to model the survival of carcasses over a given search interval. Because the time of death for detected fatalities is usually unknown, the probability of persistence cannot be calculated exactly for each carcass, but it can be estimated from the selected survival model and bootstrapped to obtain a range of estimates of *r* for each carcass.

We modeled our data using a series of models based on each of these four distributions. For each distribution, we compared models with and without explanatory variables. (An *explanatory variable* is any data set of interest that may have an influential relationship on the dependent variable, or measured outcome, of a study.) Specifically, for each distribution, we compared the following possible models: the null model, which contains no explanatory variables, a model controlling for season as an explanatory variable, a model controlling for size as an explanatory variable, and a model controlling for both season and size as explanatory variables. This resulted in four models for each distribution, for a total of 16 models.

To rank the fit of each survival model to our carcass-persistence trial data, we used Akaike's Information Criterion adjusted for sample size (AICc) (Akaike 1973). AIC and AICc are typically used to compare the relative fit of different models to a dataset. Although the absolute value of AICc may vary, the difference in AICc values among models provides information about which model is most statistically supported. The model with the lowest AICc value is typically held to be most supported by the data, but any model with a change in AICc values of less than 2 from the "best model" is considered to have strong evidence supporting it (Burnham and Anderson 2004).

2.2.2 Estimating Searcher-efficiency Rates

Searcher efficiency, or the proportion of fatalities that an observer sees, *p*, is represented most simply by the following equation:

$$p = \frac{NumberObserved}{NumberAvailable}$$

We compared four models for this dataset: the null model, a model containing size class as an explanatory variable, a model containing visibility class as an explanatory variable, and a model containing both size class and visibility class as explanatory variables.

2.2.3 Estimating Fatalities on the Project Site

The Fatality Estimator bootstrapping procedure calculates an adjusted fatality value for every fatality found based on the search interval, searcher efficiency, and carcass persistence. Because fatalities of different species and different-size feather spots are found in different vegetation heights and percent cover, fatality estimates based on different data sets with the same number of total fatalities can yield very different results. Fatalities found in tall grass, for example, are considered more difficult to find, based on the searcher-efficiency rates calculated at the CVSR Project. Therefore, fatalities found in tall grass are weighted more heavily in the overall estimate.

Within the Fatality Estimator, the bootstrapped values are automatically summed, and a total estimate and 90% confidence intervals are calculated for the Project element and each covariate combination assigned. The Fatality Estimator was developed for wind energy projects, and used individual wind turbines as the sample unit of replication. To apply this tool to the CVSR Project, we used tracker units instead of turbines as the sample unit. For the overhead lines, for which the entire length was sampled, we set the entire feature as the sample unit. For the fences, we made an estimate from the 6411.2-m length searched during weekly fatality searches as a unit, and extrapolated from the estimate to represent the total fence length of 32056 m.

Although the majority of fatalities were included in the fatality estimates, some did not meet the underlying assumptions of the fatality estimate model. Fatalities deemed older than the search interval (i.e., fatalities missed during previous searches) were not included in the Fatality Estimator because rates of imperfect efficiency (i.e., <100%) are already accounted for in the model, and including these old fatalities would falsely inflate estimates. Likewise, incidental fatalities were not included in the Fatality Estimator because they were found outside the defined search effort. Clearance fatalities more than 1 day old (>24 hours) were also excluded from estimates because time since death could not be reliably established.

When possible, we calculated fatality estimates by fatality class [a size designation of small ≤100g, or large >100 g. based on average size of species as defined in *The Sibley Guide to Birds* (Sibley 2000)], season, and cause of death; however, small sample sizes (N<5) sometimes did not allow for estimates to be calculated for all of these explanatory variables.

The date range for all fatality estimates is based on one full year where weekly fatality searches occurred across all Project elements, from 7 November 2013 to 6 November 2014. Although Arrays 1 and 2 were searched at 100% until the end of December 2013, fatalities found in trackers outside the 20% area that was established in January 2014 were excluded from all estimates.

2.2.4 Applying Control Plot Data to Adjust Fatality Rates

If we assume that control plots adequately represent background mortality that could be expected if the CVSR Project did not exist, then we should be able to estimate the mortality rates related to the presence of the Project as the difference between rates within the arrays and rates in the control plots within Conservation Lands. Any such evaluation requires that fatality rates between array areas and Conservation Lands be evaluated and applied on the same spatial and temporal scale. Control plots were designed specifically for this purpose by making them equivalent to the size of a typical tracker unit. This allowed us to calculate a per-tracker unit fatality rate for array areas, and a per-control plot fatality rate for Conservation Lands that represents the same spatial scale. Because the focus of the fatality survey effort was to develop an overall fatality rate for the Project with a certain level of precision, more effort was spent surveying tracker units within arrays than control plots within Conservation Lands. Approximately one control plot was established for every eight tracker units surveyed within the arrays. The larger sample size of tracker-unit sized plots within the arrays versus those in Conservation Lands resulted in higher precision in estimating fatality rates in the array areas as compared to Conservation Lands.

To estimate the fatality rate related to the CVSR Project, we used bootstrap methods and the results from the Fatality Estimator to estimate the mean and 90% confidence intervals of the difference between per-tracker fatality rates within array areas and per-control plot fatality rates within Conservation Lands.. In an attempt to account for differences in sample sizes between array areas and Conservation Lands, we subsampled array areas at a sample size equal to the number of control plots. By applying this method to the results from the Fatality Estimator, we adjusted the individual fatalities to account for imperfect detection due to searcher efficiency and carcass persistence rates.

Definitions:

N_C = Total number of control plots within Conservation Lands that were surveyed for the entire study period,
N_T = Total number of tracker units surveyed within array areas during the study period,
n_c = number of randomly sampled control plots,
n_t = number of randomly sampled tracker units,
F_C = Total estimated fatalities across all n_c over the study period,
F_T = Total estimated fatalities across all n_t over the study period,
F_{con} = estimated background fatality rate based upon control plots over the study period,
F_{trac} = estimated per-tracker unit fatality rate within arrays over the study period,
$F_{b.adj}$ = estimated per-tracker unit fatality rate that is adjusted by subtracting background fatality rates, and
m = the number of bootstrap iterations.
Note that $n_c = n_t = N_C$.

The bootstrap process proceeded as follows:

1. Randomly sample n_c control plots, with replacement, from the N_C control plots at the study site. Note that because we are sampling with replacement, an individual control plot may be represented more than once.
2. Based on the new random sample of n_c control plots, estimate the total fatality rate for control plots, F_C, using the Fatality Estimator .
3. Estimate the per-control plot fatality rate, which equates in spatial scale to the per-tracker unit fatality rate: $F_{con} = F_C/N_C$.
4. Randomly sample n_t tracker units, with replacement, from the N_T tracker units in the study area.
5. Based on the new random sample of n_t tracker units, estimate the total fatality rate for tracker units sampled, F_T, using the Fatality Estimator. Note that we are estimating total fatalities for N_C number of tracker units, and not for the entire facility or the N_T number of tracker units surveyed.
6. Estimate the per-tracker fatality rate: $F_{trac} = F_T/N_C$.
7. Calculate the adjusted, per-tracker fatality rate as the difference between the per-control plot fatality rates and the per-tracker fatality rates from 3 and 6, above ($F_{b.adj} = F_{trac} - F_{con}$).
8. Do this m number of times, yielding m values of $F_{b.adj}$. ($m = 2000$).
9. Estimate the adjusted, per-tracker fatality rate as the mean of the m values of $F_{b.adj}$, and the 90% confidence intervals as the 0.05 and 0.95 quantiles of those values.

Sampling only N_C trackers from the much larger N_T trackers that were actually surveyed at the site is intended to simulate a balanced paired design, as if we had sampled an equal amount of area in the arrays and within the onsite Conservation Lands. If we had not done so, our degree of confidence in the mean per-tracker unit fatality rate for array areas would be much higher than the mean control plot fatality rate in Conservation Lands due to the relatively low sample size of control plots, which could result in biased estimates. It should be noted that when we applied this analysis to results from the Fatality Estimator, we did not account for uncertainty in searcher efficiency and carcass persistence sub-models; and therefore, we invoke an assumption that the parameters of those models are known without error. Consequently, the results of this bootstrap analysis only represent error associated with the random and incomplete sampling of tracker units within arrays and control plots within onsite Conservation Lands (i.e., sampling error).

Section 3.0 Results

3.1 Weekly Searches

A total of 360 avian fatalities were found during weekly fatality searches of Project elements and control plots between 16 August 2013 and 17 November 2014 (Figures 4–11; Appendix C). An additional four clearance fatalities were also found during weekly searches. However, because time since death cannot be reliably established, we do not include clearance fatalities in any further discussion in this section. No bat fatalities were found during the current reporting period.

Of the 360 fatalities found during weekly searches, the majority (65%) was found in arrays, and 307 (85%) fatalities were year-round avian residents (Table 3).

Table 3. Number of Fatalities Found at Each Project Element, by Residency Status

	Migrant	Resident	Winter Resident	Unknown[1]	Total
Arrays	5	217	9	3	234
Control plots	1	16	0	0	17
Evaporation Pond	0	4	0	0	4
Fences	0	11	1	2	14
Gen-tie Line	14	38	11	2	65
MVOH Line	0	21	2	3	26
Total	20	307	23	10	360

Note:
[1] Unidentified species among the fatalities were grouped as having Unknown residency status.

To assess the effect of season on fatalities, we excluded fatalities from Arrays 1 and 2 that were detected outside the reduced 20% search areas before January 2014. Additionally, one fatality found in a control plot was excluded; this control plot was removed in January 2014 to coincide with the reduced search effort in Arrays 1 and 2. Inclusion of these data would inflate seasonal numbers for these areas, because a greater search effort occurred before January. However, we excluded these data only for the analysis presented here, in Section 3.1. All subsequent sections include all available data from this reporting period.

There was seasonal variation in fatalities across the different Project elements (Table 4; Figures 12-16). The arrays and Gen-tie Line showed the most variation in the numbers of fatalities found across seasons (Figures 12 and 15). The largest number of fatalities in the arrays occurred in winter, accounting for 48.3% of all array fatalities (Table 4). There was a steady decline in fatalities in the arrays after winter, and this decline carried into fall 2014. Also, array fatalities were lower in fall 2014 compared with fall 2013. The largest number of fatalities along the Gen-tie Line occurred in fall 2013, accounting for 39.06% of all Gen-tie Line fatalities. Gen-tie Line fatalities declined after fall 2013 but remained fairly constant. Like array fatalities, Gen-tie Line fatalities in fall 2014 were lower than in fall 2013. There was also a slight spike in fatalities in the winter along the MVOH Line, but overall numbers for this Project element were too low to establish trends. Likewise, fatalities found along the fences and at the Evaporation Pond and control plots were too few to establish trends.

3.2 Repeat Searches

This section presents the results of all repeat searches, which (in the final year of monitoring) were conducted from 16 August through 31 December 2013. For reasons discussed in Section 2.1.2, we did not calculate fatality estimates based on the results of the 5-day repeat searches or the 1-day repeat searches in 5-day search areas for this report. However, because the 1-day repeat searches of weekly search areas affected the search interval for weekly searches and occurred in overlapping areas, these results were included in total fatality estimates (consistent with the first annual report [HTH 2014a]).

In total, 54 fatalities were detected during repeat searches across all Project elements and control plots. Eighteen of these fatalities were clearance fatalities and are not discussed further, for reasons described earlier. Therefore, the effective sample size for repeat searches was 36 fatalities. Combining the results of all repeat searches, the largest percentage (83.3%) of fatalities was found in the arrays. Details of fatalities found during each type of repeat search are presented below.

3.2.1 5-Day Repeat Searches

Nineteen fatalities were found during 5-day repeat searches between 16 August and 31 December 2013. An additional 18 clearance fatalities were found but not used in any analyses. One of these fatalities was found directly under the MVOH Line, suggesting collision as the cause of death (>50% certainty, or Probable). The cause of death for the remainder of fatalities was unknown.

3.2.2 1-Day Repeat Searches of Weekly Search Areas

Fifteen fatalities were found during 1-day repeat searches of weekly search areas during this annual reporting period. Two feather spots were found directly under the Gen-tie Line and were considered to have >50% probability of death by collision (Probable). The carcass of a mourning dove was found in Array 2. This carcass had bruising on its right foot and signs of trauma to its right shoulder and chest, suggesting that collision was a Valid (>90% certainty) cause of death. The cause of death for the remainder of fatalities was unknown.

3.2.3 1-Day Repeat Searches of 5-Day Repeat Search Areas

Two fatalities were found during 1-day repeat searches of 5-day repeat search areas between 16 August and 31 December 2013. One was the feather spot of a mourning dove, found along the fence in Array 8 on 18 October. The second was the feather spot of a common raven (*Corvus corax*), found in Array 9 on 8 November. The causes of death could not be discerned for these fatalities.

3.3 Incidental Fatalities

Thirty-five incidental fatalities were found between 16 August 2013 and 17 November 2014. This number includes two fatalities that were found in onsite Conservation Lands. Of the total number of fatalities found incidentally, 46.8% were found in arrays. Only one fatality was found and reported by CVSR Project staff.

Two ravens were found in separate events and both were suspected to have died from electrocution. A pied-billed grebe (*Podilymbus podiceps*) was observed being consumed by a coyote (*Canis latrans*), but because grebes are obligate waterbirds, collision was assigned as the cause of death. A mourning dove was also assumed to have died from collision after a smudge mark was discovered on an otherwise clean panel above a feather spot.

3.4 Trends in Total Fatalities

The subsections that follow present combined counts of fatalities found during weekly searches, repeat searches, and incidental detections. The purpose of combining these counts is to use all available data to help illustrate possible trends associated with Project elements and species.

Overall, 453 fatalities were found during weekly and repeat searches of Project elements, and incidentally. Twenty two of these fatalities were clearance fatalities, and 2 of the incidentally discovered fatalities were found on onsite Conservation Lands. In this section, we do not include any further discussion of clearance fatalities or fatalities found on Conservation Lands outside of control plots. Therefore, the effective sample size discussed for all Project elements in this section is 429 fatalities. The majority of these fatalities were found in arrays (Figure 17).

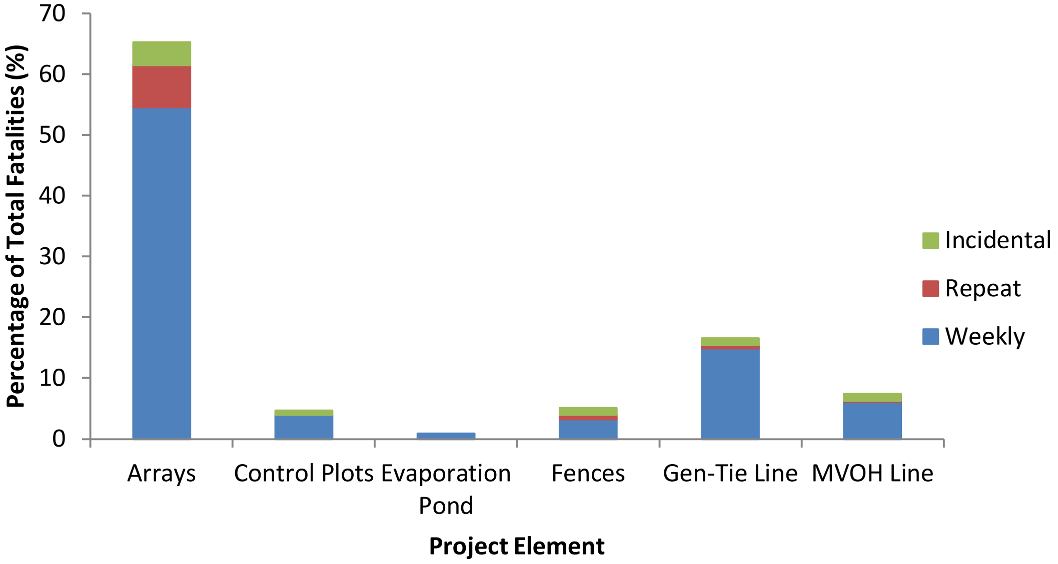

Figure 17. Percentage of Total Fatalities Found during Weekly Searches, Repeat Searches, and Incidentally at All Project Elements (N=429)

Note: Incidental fatalities found in onsite Conservation Lands, and clearance fatalities, are not included.

3.4.1 Cause of Death

Of the 429 fatalities found in Project elements and control plots, the cause of death for the majority (80.9%) could not be reliably discerned. Seventy-three (17.0%) were believed to have died as a result of a collision (50 on the Gen-tie Line, 15 on the MVOH Line, 7 with solar panels, and 1 with a perimeter fence). Two fatalities were believed to be electrocuted (0.5%). Six (1.4%) were believed to have been killed by predators, and one (0.2%) was believed to have died from disease.

Both electrocution deaths occurred along the MVOH Line (Figure 18). Although none of the fatalities found in control plots had a known cause of death, >45% of the fatalities found along the Gen-tie Line and MVOH Line were believed to be the result of collision. This determination was based primarily on the location of fatalities directly or nearly directly under the lines. Only eight fatalities found in arrays were linked to known causes of death (seven panel collisions and one predation event), and the remaining 97.1% of fatalities found in arrays were assigned an unknown cause of death.

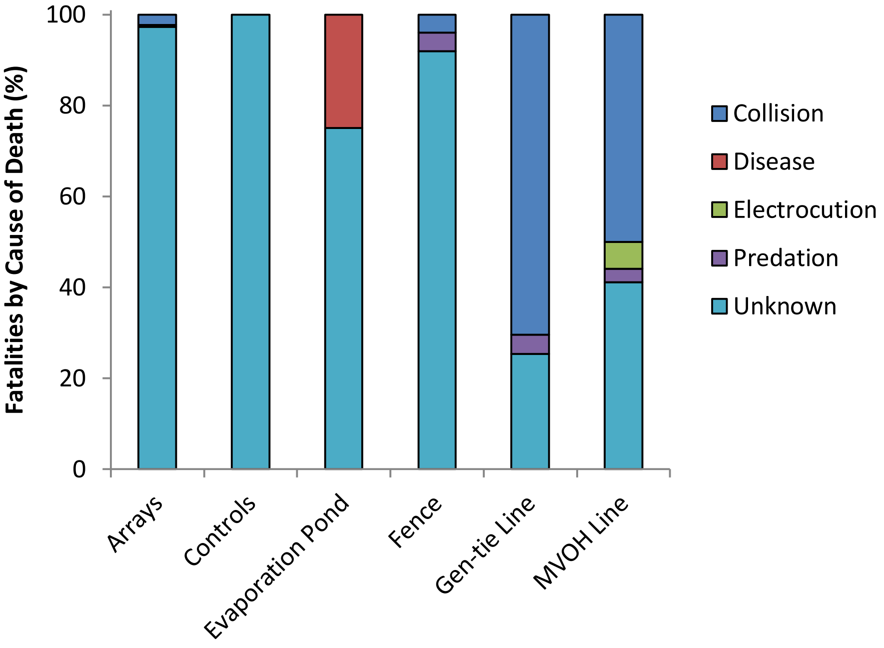

Figure 18. Cause of Death by Project Element

3.4.2 Fatalities by Species

In total, we found fatalities from 36 known avian species and 5 fatalities that did not provide enough information to assign them to a species (Table 5). With the exception of two American coots (*Fulica americana*) found in Arrays 4 and 5, and one pied-billed grebe found in Array 7, all known fatalities were terrestrial avian species.

Mourning doves accounted for the greatest percentage of fatalities (38.9%) found, with horned larks and house finches (*Carpodacus mexicanus*) composing the second (13.5%) and third (13.1%) most frequently observed fatalities, respectively. Fatalities from three special-status species, burrowing owl (*Athene cunicularia*), loggerhead shrike (*Lanius ludovicianus*), and yellow warblers (*Setophaga petechial*) were detected during weekly searches, but combined, these fatalities accounted for only about 3% of the total number of fatalities found during weekly searches.

Table 5. Number of Fatalities Found, by Species

Species	Scientific Name	AOU Code[4]	Fatalities Recorded
Mourning dove[2]	*Zenaida macroura*	MODO	167
Horned lark[1]	*Eremophila alpestris*	HOLA	58
House finch[1]	*Haemorhous mexicanus*	HOFI	56

Wilson's warbler[1]	*Wilsonia pusilla*	WIWA	1
Total			**429**

Notes:
[1] Denotes species modeled as small birds in the Fatality Estimator.
[2] Denotes species modeled as large birds in the Fatality Estimator.
[3] These unidentifiable species were examined and determined to be large or small birds for the purposes of the Fatality Estimator on a case-by-case basis.
[4] Codes designated by the American Ornithologists' Union (AOU) Check-list of North American Birds (AOU 2015). Codes for unknown species are not designated by the AOU. For purposes of this report, unidentifiable large birds, small birds, raptors, or passerines are designated as UNKN. Unidentifiable warblers are designated as UNWA.

3.4.3 Fatalities by Residency Group

When comparing migrants (transient species traveling between summer breeding grounds and wintering grounds), residents (species living in the region year-round), and winter residents (species present in the region only in the winter), across all Project elements, residents accounted for the highest proportion of fatalities in arrays (70.46%), compared with all other Project elements (Table 6). Migrants and winter residents accounted for the highest number of fatalities along the Gen-tie Line (63.64% and 51.85%, respectively), compared with all other Project elements.

Table 6. Percent of Residency Group Fatalities across Project Elements (N=429)

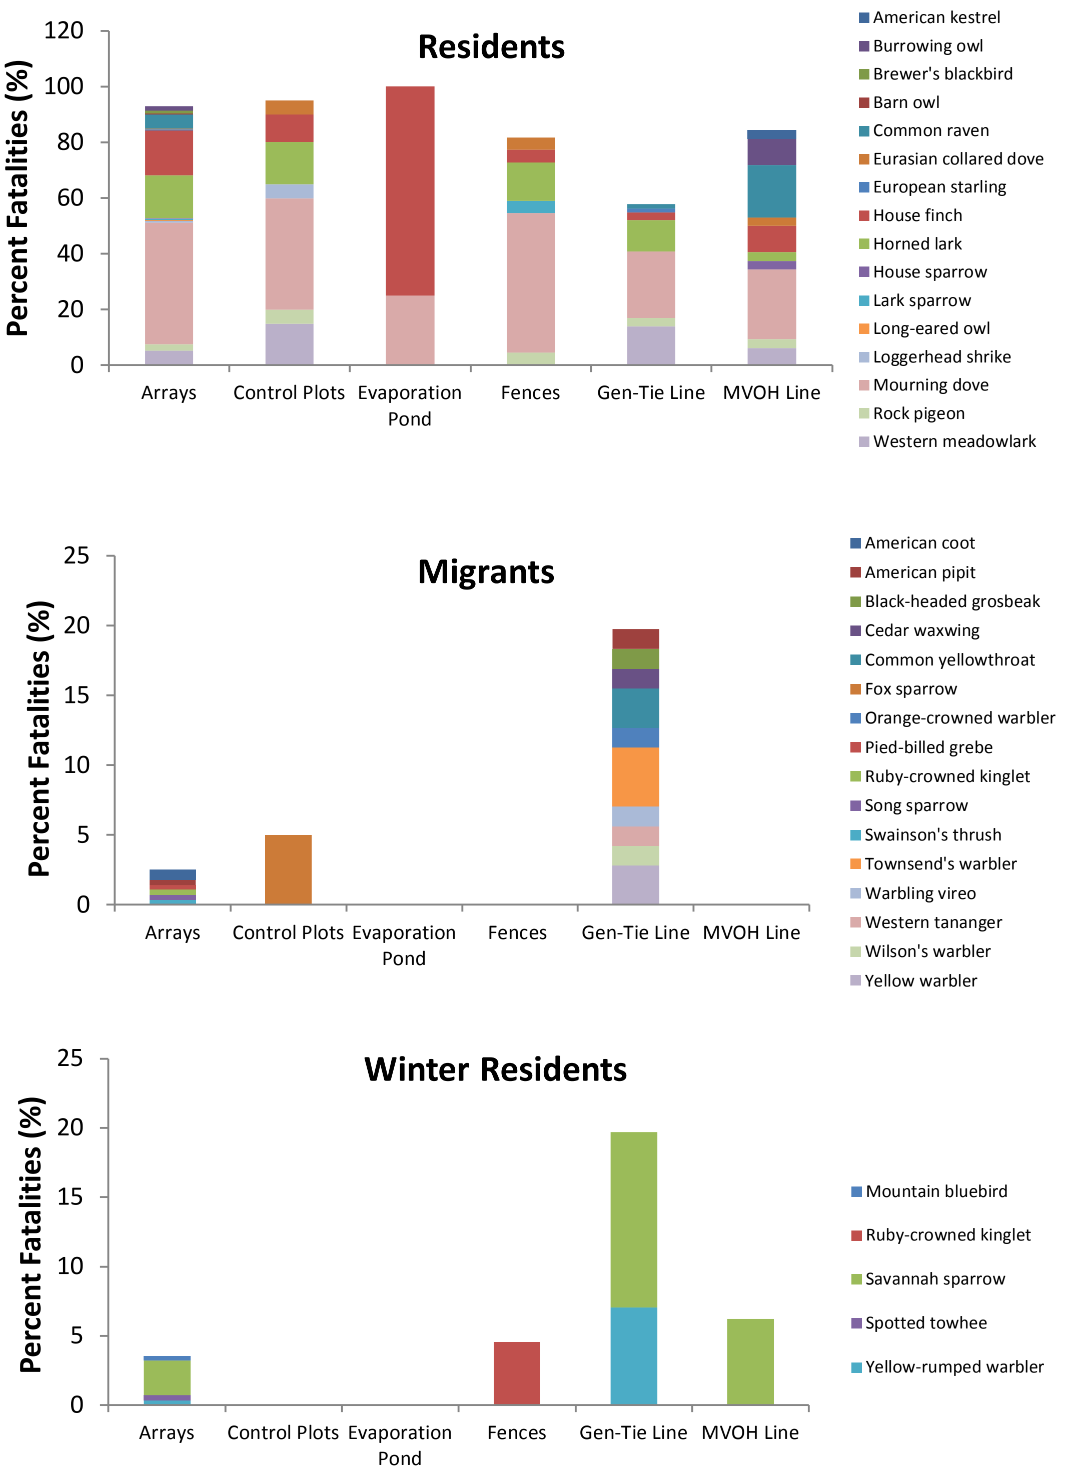
	Percent (%) of Fatalities			
Project Element	**Migrant**	**Resident**	**Winter Resident**	**Unknown**
Arrays	31.82	70.46	37.04	27.27
Control plots	4.55	5.15	0.00	0.00
Evaporation Pond	0.00	1.08	0.00	0.00
Fences	0.00	4.88	3.70	27.27
Gen-Tie Line	63.64	11.11	51.85	18.18
MVOH Line	0.00	7.32	7.41	27.27
Residency Group Total	100	100	100	100

Within each Project element, avian resident fatalities accounted for the highest percentage of fatalities (Table 7, Figure 19). Migrant and winter resident fatalities accounted for the second highest percentage of fatalities (19.72% and 19.72%), but only with the Gen-tie Line.

Table 7. Percent of Residency Group Fatalities within Project Elements (N=429)

	Percent (%) of Fatalities in Each Project Element				
Project Element	**Migrant**	**Resident**	**Winter Resident**	**Unknown**	**Total Percent Fatalities**
Arrays	2.50	92.86	3.57	1.07	100
Control plots	5.00	95.00	0.00	0.00	100
Evaporation Pond	0.00	100.00	0.00	0.00	100
Fences	0.00	81.82	4.55	13.64	100
Gen-tie Line	19.72	57.75	19.72	2.82	100
MVOH Line	0.00	84.38	6.25	9.38	100

Within each Project element, the highest species richness of fatalities was found in the arrays and along the Gen-tie Line, but the overall species composition of fatalities for these Project elements differed. The MVOH line had the third highest species richness of fatalities. In contrast, no migratory species fatalities were found along the MVOH line. The lowest species richness of fatalities was found in control plots, fences and the Evaporation Pond.



Notes: Residency status is based on knowledge of species typically found on the Project site at different times of the year. Unknown species (N=11) are not included in this figure.

Figure 19. Fatalities, by Species and Residency Group, as Percentages of the Total Fatalities in Each Project Element (N=418)

3.4.4 Gen-tie Line Trends by Elevation

Both overhead lines (the Gen-tie and the MVOH Lines) had a high percentage of fatalities with known causes of death. However, the seasonal graphs of the Gen-tie Line monitoring results demonstrate peaks that could be associated with migratory activity, whereas the MVOH Line data did not. The Gen-tie Line is unique among the other Project elements in several ways: it is the only Project element that has a variety of elevations along its length, it crosses over a tamarisk wetland in the area north of State Route 58, and the powerlines are higher above the ground than those associated with the MVOH Line.

To help determine what factor had the largest effect on the differences in fatality rates and species richness of fatalities found along the two lines, we assessed the numbers of fatalities along the Gen-tie Line by elevation. Although elevation consistently increases as the tower numbers increase from the substation (Tower 1) to the Caliente switching station (Tower 23), the number of fatalities found between towers does not indicate a pattern (Figure 20). Similarly, the number of species found at different areas along the Gen-tie Line did not increase with elevation, and did not cluster around the tamarisk wetland located between Gen-tie Line towers 17 and 18 (Figure 21).

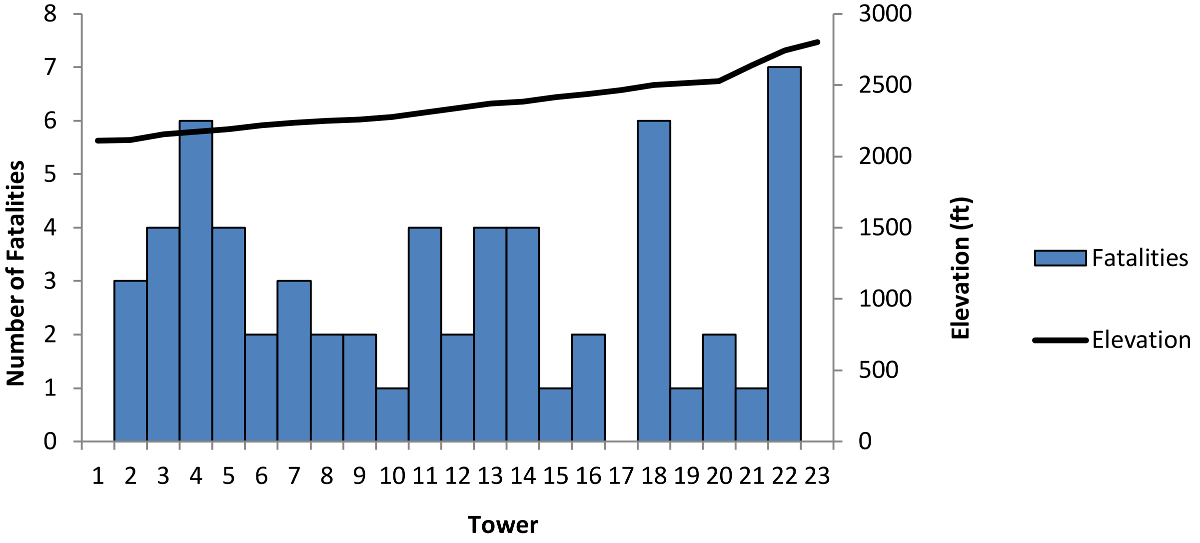


Figure 20. Number of Fatalities along the Gen-tie Line, by Elevation and Tower Number

Note: Fatalities are grouped from tower to tower (e.g., all fatalities found between the substation and Tower 1 are graphed under Tower 1).

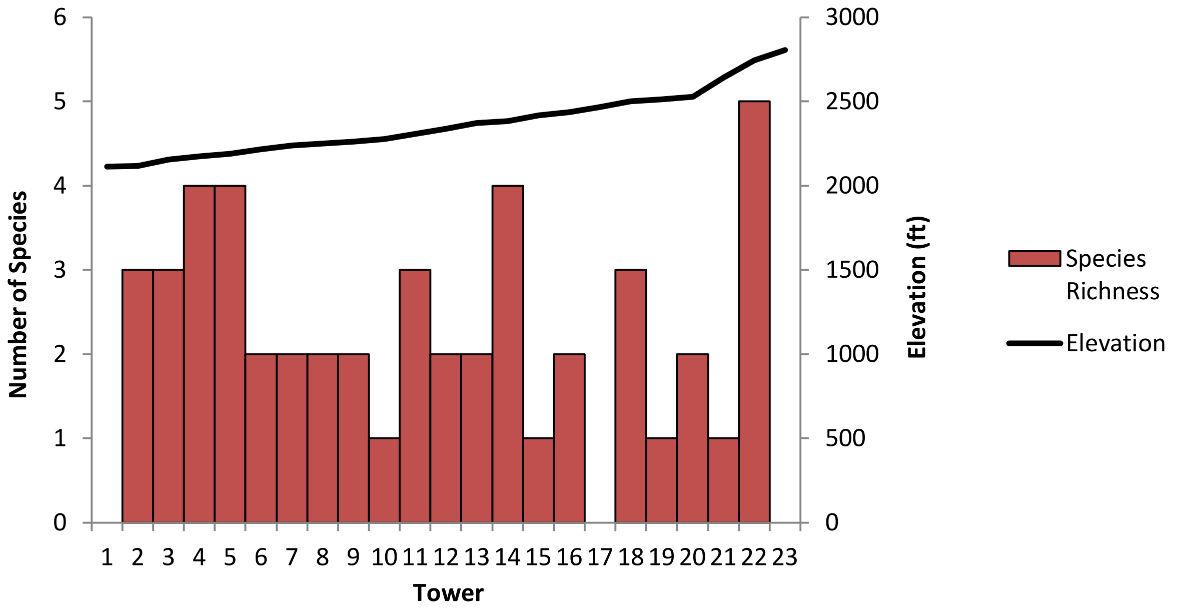

Figure 21. Species Richness of Fatalities Found along the Gen-tie Line, by Elevation and Tower Number

Note: Fatalities are grouped from tower to tower (e.g., all fatalities found between the substation and Tower 1 are graphed under Tower 1. The tamarisk wetland is located between Towers 17 and 18).

3.5 Fatality Estimates

3.5.1 Carcass-persistence Rates

3.5.1.1 Overall Project Site Persistence Rates

Between 15 October 2012 and 11 March 2014, we conducted carcass-persistence trials using 206 fatality plants. Eleven fatality plants were excluded because full persistence data were not collected (i.e., carcasses were collected by staff after the initial scavenging event). One-hundred and five carcasses were placed after the first annual reporting period, but because the results of both years were used to inform persistence times in the Fatality Estimator, the results of all trials are presented here.

From our 30 feather spot persistence trials, we calculated that feather spots persisted an average of 18 days on bare ground, 35 days in low grass (≤25 cm), and 45 days in medium or high grass (>25 cm). We applied these values as adjustment factors for all feather spots that persisted after scavenging, and these are the values we report below, unless otherwise noted. Feather spots that were left on low grass with <50% cover in a 1-m^2 area were assigned the same adjustment factor as those on bare ground.

3.5.1.2 Persistence Rates by Explanatory Variables

Observed scavenger species included common ravens, which scavenged 46.2% of all planted fatalities; San Joaquin kit foxes (*Vulpes macrotis mutica)*, which scavenged 22.1% of all planted fatalities; coyotes, which scavenged 5.6% of all planted fatalities; and one of each of the following: a turkey vulture (*Cathartes aura*), a prairie falcon

(*Falco mexicanus*), and a red-tailed hawk (*Buteo jamaicensis*) (Figure 22). Two planted carcasses, a great horned owl (*Bubo virginianus*) and a red-tailed hawk, remained mostly intact for the full 6-week monitoring period, so no final scavenger species was assigned to these carcasses. Unknown scavengers accounted for 23.6% of all scavenging events.

After 7 days, only 10.8% of all small carcasses remained unscavenged. However, 25.0% of all small carcasses and resultant feather spots remained in place (Figure 23). This effect was even more dramatic for large carcasses: whereas only 25.3% of all carcasses remained after a week, more than half (65.7%) of all large carcasses either remained in place or left feather spots behind.

Figure 22. Scavenger Species Documented in Carcass-persistence Trials

Notes: Clockwise from top left, recorded scavenger species were as follows: common raven, San Joaquin kit fox, turkey vulture, red-tailed hawk, prairie falcon, and a coyote.

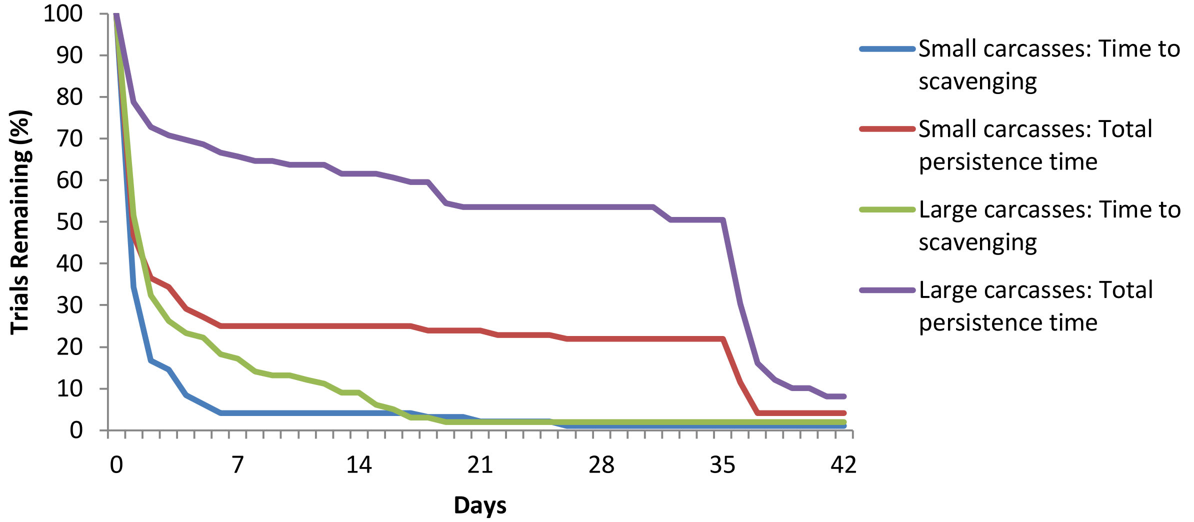

Figure 23. Percent of All Carcasses and Resultant Feather Spots Remaining Over Time (N=195)

Time to scavenging was longest for both large and small carcasses in the winter. Assuming conservatively that carcasses would not persist past the 6-week trial period, mean carcass persistence over the entire year was 9.3 days for small carcasses and 22.2 days for large carcasses. Total persistence times did not exhibit a clear seasonal pattern, but clearly varied by carcass size (Table 8).

Table 8. Average Time to Scavenging and Average Total Persistence, by Size and Season

Season	Carcass Size	N	Average Time to Scavenging (days)	Average Total Persistence (days)
Fall	Small	29	1.52	11.91
	Large	28	2.77	17.80
Winter	Small	29	3.56	9.87
	Large	30	5.16	17.27
Spring	Small	22	1.62	4.30
	Large	28	4.03	30.51
Summer	Small	16	1.08	12.02
	Large	13	2.53	27.34

3.5.1.3 Model Selection for Carcass-persistence Decay Curve

Based on the carcass-persistence data, we compared 16 possible models. The model with the lowest AICc had a lognormal distribution and controlled for carcass size but not season (Table 9). Because the ΔAICc is >2 between this model and the next ranked model, this model alone has substantial support, and we used this model in the fatality estimates.

Table 9. AICc Values for Each of 16 Models of Carcass Persistence

Distribution	Model Formula	AICc	Shape
Exponential	Null	1012.0	1.0
Exponential	Season	1010.7	1.0
Exponential	Size	946.6	1.0
Exponential	Season + Size	949.4	1.0
Loglogistic	Null	680.1	2.41
Loglogistic	Season	684.1	2.39
Loglogistic	Size	637.2	2.06
Loglogistic	Season + Size	639.8	2.04
Lognormal	Null	671.7	3.92
Lognormal	Season	675.7	3.89
Lognormal	**Size**	**631.8**	**3.45**
Lognormal	Season + Size	634.4	3.41
Weibull	Null	699.3	3.21
Weibull	Season	702.3	3.19
Weibull	Size	659.2	2.96
Weibull	Season + Size	663.1	2.95

Notes: AICc = Akaike's Information Criterion, adjusted for sample size. Lognormal model in **bold** is best supported. "Null" indicates models with no explanatory variables.

3.5.2 Searcher-efficiency Rates

Between 5 September 2012 and 31 July 2014, we conducted 434 searcher-efficiency trials in all operational Project elements throughout the site. Three trial specimens (two large carcasses and one small carcass) were removed by scavengers and not used in analysis. Therefore, we used a total of 431 fatality trial specimens: 113 small and 98 large feather spots, and 113 small and 107 large carcasses. Fatality plants were placed in areas with various combinations of vegetation height and percent cover.

Overall searcher efficiency was 50.8% (Table 10). When accounting for size and visibility class, each on their own, searchers were most effective at detecting large carcasses, large feather spots, and fatality plants placed in the Easy visibility class. When accounting for size and visibility class together, searcher efficiency for large carcasses and large feather spots in the Easy visibility class was 80% and 77.1%, respectively. Searcher efficiency was slightly lower for large carcasses in the Moderate visibility class, at 66.7%, and was 50.9% for small carcasses in the Easy visibility class. At 25.5%, searchers were least effective at finding small feather spots in the Moderate visibility class.

Table 10. Results from Searcher-efficiency Trials, September 2012 through July 2014

Category	Detection Rate (%)	N
Overall	50.8	431
Size Class		
Large carcass	72.9	107
Small carcass	41.6	113
Large feather spot	65.3	98
Small feather spot	26.5	113
Visibility Class		
Easy visibility	57.3	211
Moderate visibility	44.5	220
Size Class and Visibility Class		
Large carcass, Easy visibility	80.0	50
Large carcass, Moderate visibility	66.7	57
Small carcass, Easy visibility	50.9	55
Small carcass, Moderate visibility	32.8	58
Large feather spot, Easy visibility	77.1	48
Large feather spot, Moderate visibility	54.0	50
Small feather spot, Easy visibility	27.6	58
Small feather spot, Moderate visibility	25.5	55

3.5.2.1 Model Selection

Based on the searcher-efficiency trial data, we compared four possible models. The model with the lowest AICc controlled for both visibility class and size class (Table 11). Because the ΔAICc is >2 between this model and the next ranked model, this model alone has substantial support, and we used this model in the fatality estimates.

Table 11. AICc Ranking of Searcher-efficiency Models

Model	AICc
Null	599.39
Visibility	594.33
Size Class	543.89
Size Class + Visibility	**536.23**

Notes: AICc = Akaike's Information Criterion, adjusted for sample size.
Model in **bold** is best supported.

3.5.3 Fatality Estimates for Known Causes

After determining the proper model structure for both searcher-efficiency and carcass-persistence trials, we ran a series of fatality estimates. We report fatality estimates only for areas and categories in which more than five fatality detections occurred, because using the Fatality Estimator with five or fewer detections produces highly biased values due to the small sample size.

Fatality estimates were calculated separately for each Project element, with the exception of the Evaporation Pond, where a low sample size precluded running a fatality estimate. Estimates are first provided for fatalities where the cause of death was determined based on direct evidence of collision or electrocution. Following these estimates, we provide estimates for fatalities where the cause of death could not be determined or was natural (i.e., cause of death was disease or predation) (Section 3.5.4).

3.5.3.1 Total Fatality Estimates for Known Causes

Of the 53 fatalities for which the cause of death could be determined, 40 were included in the fatality estimate models (Table 12). Two from the arrays were excluded from the model but then added, unadjusted, to the estimator output, to produce the total fatality estimate for known causes. Eleven fatalities with evidence of electrocution or collision were not included in the fatality estimates: four were excluded because they were found incidentally, five were excluded because they were older than the search interval, and two were excluded because they were found in Array 1 and 2 outside of the 20% search areas established in January 2014.

Table 12. Number of Detections Based on Known Causes in Each Project Element, and Number Included in Fatality Estimates, 7 November 2013 to 6 November 2014

	Fatalities Detected		
Project Element	**Number Included**	**Number Excluded**	**Total Found**
Arrays	0	6[1,2]	6
Control plots	0	0	0
Evaporation Pond	0	0	0
Fences	0	0	0
Gen-tie Line	29	5[3]	34
MVOH Line	11	2[4]	13
Total	**40**	**13**	**53**

Notes:

[1] Two fatalities were excluded because they were incidentals and two fatalities were excluded because they were found outside of the 20% areas for Array 1 and 2 prior to January 2014.

[2] No estimate was provided for this element because of the low sample size; the remaining two fatalities (see Note 1) were added unadjusted to the overall estimator output.

[3] Five fatalities were excluded because they were older than the search interval.

[4] Two electrocuted fatalities were excluded because they were found incidentally.

During the period of 7 November 2013 to 6 November 2014, an estimated 126 birds died from electrocution- or collision-related causes (90% confidence interval: 106–155) at the Project site (Table 13).

Table 13. Estimates of Total Fatalities with Known Causes, 7 November 2013 to 6 November 2014

Project Element	Number of Fatalities Included in Model	Estimate of Fatalities (with Lower and Upper 90% Confidence Limits)
Arrays	0	n/a[1]
Control plots	0	n/a[2]
Evaporation Pond	0	n/a[2]
Fences	0	n/a[2]
Gen-tie Line	29	99 (83, 123)
MVOH Line	11	25 (21, 30)
Total for Project site[1]	**40**	**126 (106, 155)[1]**

Notes:

[1] The two fatalities in the arrays were added unadjusted to the total fatality estimate for the site.

[2] n/a = not applicable; no fatalities caused by electrocution or collision were found in these elements.

3.5.3.2 Fatality Estimates by Project Element

No fatalities that were found in control plots, at the Evaporation Pond, or along fences provided direct evidence of electrocution or collision, so we do not provide a fatality estimate for known causes based on fatalities found in these project elements. Likewise, due to the low number of fatalities found with known causes of death in the array areas, we do not provide a fatality estimate for the array areas.

The overhead powerlines were the only areas for which we estimated the number of fatalities caused by collision or electrocution. Ninety-nine fatalities were estimated to have occurred as a result of collision along the Gen-tie Line (90% confidence interval: 83–123; Table 14). Seasonal estimates were not made for the Gen-tie Line by cause of death because very few fatalities were found in the winter (N=4).

Table 14. Fatality Estimates for the Gen-tie Line, by Cause of Death (Electrocution or Collision), and Fatality Class, 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimated Total Number of Fatalities[1]	Lower and Upper 90% Confidence Limits
Cause of Death			
Electrocution	0	0	n/a[1,2]
Collision	29	99	83, 123
Fatality Class			
Large	7	19	15, 24
Small	22	81	65, 104

Notes:

[1] The bootstrap methods used to produce the fatality estimate produce estimates for the entire dataset that differ slightly from the sum of estimates for constituent subgroups of the data.
[2] n/a= not applicable; no electrocution-related fatalities were found in the Gen-tie Line area.

An estimated 25 fatalities occurred along the MVOH Line as a result of collision between 7 November 2013 and 6 November 2014 (90% confidence interval: 21–30; Table 15). Seasonal estimates for the MVOH Line were not calculated due to low sample sizes in the summer, fall, and winter (N=1, N=2, and N=2, respectively). Estimates by size also were not calculated, because of a low sample size for small birds (N=2).

Table 15. Fatality Estimates for the MVOH Line by Cause of Death (Electrocution or Collision), 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimated Total Number of Fatalities	Lower and Upper 90% Confidence Limits
Cause of Death			
Electrocution	0[1]	0	n/a[2]
Collision	11	25	21, 30

Notes:
[1] Two electrocution-related fatalities were excluded from the model because they were found incidentally.
[2] n/a = not applicable; no electrocution-related fatalities found along the MVOH Line were included in the model.

3.5.4 Fatality Estimates for Unknown and Natural Causes of Death

For the purposes of these estimates, fatalities with suspected natural causes of death (i.e., predation or disease) are included in this section, along with fatalities for which cause of death could not be determined. We did not calculate separate estimates for predation or disease; instead, these fatalities are grouped in with the total estimates for fatalities with unknown causes of death. Of the 251 fatalities for which the cause of death was natural or could not be determined, 186 were included in the fatality estimate models (Table 16). Of the excluded fatalities, four each from the Evaporation Pond and Gen-tie Line were later added unadjusted to the estimator output, to produce the total fatality estimate for unknown causes. There were 65 fatalities with an unknown or natural cause of death that were not included in the fatality estimates; 20 were excluded because they were found incidentally, 9 were excluded because they were older than the search interval, 1 was excluded because it was found in a control plot that was removed in January 2014 when the search areas for Arrays 1 and 2 were reduced to 20%, and 27 were excluded because they were found in Array 1 and 2 outside of the 20% search areas established in January 2014.

Table 16. Number of Unknown-cause and Natural Fatalities Detected in Each Project Element, and Number Included in Fatality Estimates, 7 November 2013 to 6 November 2014

	Fatalities Detected		
Project Element	**Number Included**	**Number Excluded**	**Total Found**
Arrays	150	45[1]	195
Control plots	14	4[2]	18
Evaporation Pond	0	4[3]	4
Fences	11	4[4]	15
Gen-tie Line	0	4[5]	4
MVOH Line	11	4[6]	15
Total	**186**	**65**	**251**

Notes:

[1] Seven fatalities were excluded because they were older than the search period, 11 fatalities were excluded because they were found incidentally, and 27 were excluded because they were found outside of the 20% search areas for Arrays 1 and 2 prior to January 2014.

[2] Three fatalities were excluded because they were found incidentally, and one fatality was excluded because it was in a control plot that was removed when the search areas for Array 1 and 2 were reduced to 20%.

[3] No estimate was provided for these elements because of the low sample size; however, these detections were later added unadjusted to the estimator output.

[4] Three fatalities were excluded because they were found incidentally, and one fatality was excluded because it was older than the search interval.

[5] No estimate was provided for these elements because of the low sample size; however, these detections were later added unadjusted to the estimator output.

[6] Three fatalities were excluded because they were found incidentally, and one fatality was excluded because it was older than the search interval.

During the period of 7 November 2013 to 6 November 2014, an estimated 2597 birds died from unknown causes (90% confidence interval: 2116-3334) at the Project site (Table 17).

Table 17. Estimates of Unknown-cause and Natural Fatalities, 7 November 2013 to 6 November 2014

Project Element	Number of Fatalities Included in Model	Estimate of Fatalities (with Lower and Upper 90% Confidence Limits)
Arrays	150	2314 (1890, 2965)
Control plots	14	52 (31, 81)
Evaporation Pond	0[1]	n/a[2]
Fences	11	185 (155, 230)
Gen-tie Line	0[1]	n/a[2]
MVOH Line	11	39 (32, 50)
Total for Project site[1]	**186**	**2598 (2116, 3334)**[1]

Notes:

[1] In total, eight fatalities with unknown or natural causes of death were found in the Evaporation Pond area and the Gen-tie Line area. These were added, unadjusted, to the total fatality estimate for the site.

[2] n/a = not applicable; there were fewer than five fatalities in this group. However, the unadjusted numbers were added to the fatality estimates and confidence intervals.

3.5.4.1 Fatality Estimates by Project Element

Because few fatalities were found in the Evaporation Pond and few with unknown causes of death were found along the Gen-tie Line, we do not provide fatality estimates for these fatalities here.

An estimated 2314 fatalities (90% confidence interval: 1890–2965) occurred in the arrays from unknown or natural causes in the year 7 November 2013 to 6 November 2014 (Table 18). The estimated number of fatalities per tracker in the arrays was 2.24 (90% confidence interval: 1.83–2.87), whereas in the control plots it was 1.72 (90% confidence interval: 1.05–2.68; Table 19).

Table 18. Fatality Estimates for the Arrays, by Cause of Death (Unknown), Fatality Class and Season, 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimate of Fatalities per Tracker[1]	Lower and Upper 90% Confidence Limits	Estimated Total Number of Fatalities[1]	Lower and Upper 90% Confidence Limits
Cause of Death					
Unknown	150	2.24	1.83, 2.87	2314	1890, 2965
Fatality Class					
Large	84	0.89	0.69, 1.17	920	712, 1209
Small	66	1.34	0.97, 1.89	1385	1002, 1953
Season					
Fall	28	0.32	0.2, 0.46	331	206, 476
Winter	85	1.24	0.94, 1.69	1281	971, 1746

Spring	27	0.47	0.27, 0.77	486	278, 796
Summer	10	0.21	0.07, 0.42	217	72, 434

Note:
[1] The bootstrap methods used to produce the fatality estimate produce estimates for the entire dataset that differ slightly from the sum of estimates for constituent subgroups of the data.

Table 19. Fatality Estimates for the Control Plots, by Cause of Death (Unknown), Fatality Class, and Season, 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimate of Fatalities per Tracker[1]	Lower and Upper 90% Confidence Limits	Estimated Total Number of Fatalities[1,2]	Lower and Upper 90% Confidence Limits
Cause of Death					
Unknown	14	1.72	1.05, 2.68	52	31, 81
Fatality Class					
Large	6	0.66	0.27, 1.23	20	8, 37
Small	8	1.06	0.33, 2.0	32	9, 60

Notes:
[1] The bootstrap methods used to produce the fatality estimate produce estimates for the entire dataset that differ slightly from the sum of estimates for constituent subgroups of the data.
[2] Estimated total is for 30 control plots.

An estimated 185 fatalities (90% confidence interval range: 155–230; Table 20) occurred along the fenceline between the dates of 7 November 2013 to 6 November 2014. An estimated 39 fatalities occurred (90% confidence interval range: 32–50) along the MVOH Line that could be attributed to unknown or natural causes (Table 21).

Table 20. Fatality Estimates for the Fences[1], by Cause of Death (Unknown) and Fatality Class, 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimated Total Number of Fatalities[2]	Lower and Upper 90% Confidence Limits
Cause of Death			
Unknown	11	185	155, 230
Fatality Class			
Large	6	85	65, 105
Small	5	105	80, 135

Notes:
[1] Estimates were made from 6411.2-m area searched during regular fatality searches and extrapolated to represent total fence area of 32,056 m.
[2] Bootstrap methods used to produce the fatality estimate produce estimates for the entire dataset that differ slightly from the sum of estimates for constituent subgroups of the data.

Table 21. Fatality Estimates for the MVOH Line, by Cause of Death (Unknown), 7 November 2013 to 6 November 2014

	Number of Detections Included in Model	Estimated Total Number of Fatalities	90% Confidence Intervals
Cause of Death			
Unknown	11	39	32, 50

3.6 Annual Background-Adjusted per-Tracker Unit Fatality Rates

The mean annual per-tracker unit fatality rate within arrays (F_{trac}), and per-control plot fatality rate within Conservation Lands (F_{con}), based on bootstrap samples were 2.24 (90% confidence interval range: 1.32 – 3.28) and 1.73 (90% confidence interval range: 0.86 – 2.74), respectively. Note that these bootstrapped estimates and confidence intervals differ slightly from those of the observed data, and are only presented here to give context for the background-adjusted estimate. The mean annual background-adjusted per-tracker unit fatality rate ($F_{b.adj}$) was 0.51 (90% confidence interval range: -0.83-1.81). The mean annual background-adjusted estimate of the number of fatalities within arrays was 526 for the period of 7 November 2013 to 6 November 2014.

Table 22. Resampled Fatality Estimates for the Control Plots, Project Plots, and Background Adjusted Fatality Estimates, 7 November 2013 to 6 November 2014. Based on 2000 iterations

Site	Mean Bootstrapped Fatality/Plot Estimate	Lower and Upper 90% Confidence Limits
Array Tracker Unit Plots	2.24	1.32, 3.28
Control Plots	1.73	0.86, 2.74
Adjusted Fatality Estimate	0.51	-0.83, 1.81[1]

[1] Negative values occur when control plot estimates exceed array tracker unit plot estimates.

Section 4.0 Discussion

This section discusses the patterns observed through monitoring, provides descriptive statistics of trends, and relates these patterns and trends to avian use of the site, and current and future research on comparable topics.

4.1 Patterns Observed in Fatality Detection Efforts

4.1.1 Avian Abundance

Fatalities in the arrays and Gen-tie Line exhibited the most seasonal variation, with definitive spikes in winter and fall 2013, respectively. Overall fatality trends in the arrays from fall 2013 through fall 2014 appear to parallel avian abundance during the same period, which was quantified during avian activity surveys conducted throughout the site and in adjacent offsite areas, as part of ABPP implementation. Avian abundance was moderately low in fall 2013, increased in winter 2013, and then steadily declined from spring to summer, with a small spike again in fall 2014 (HTH 2015). Although we cannot say definitively what the cause of death was for many of the array avian fatalities, it appears that these fatalities mirror trends in abundance; in other words, when birds are more abundant, so are array fatalities. For instance, Columbid activity (i.e., mourning doves) showed a strong seasonal pattern, with average detection rates during point counts highest in winter (HTH 2015). In contrast, although there was a spike in fatalities in fall 2013 along the Gen-tie Line, fatalities there did not parallel avian abundance seasonally in the region.

As defined by the National Drought Monitor (National Drought Mitigation Center 2014), the onset of prolonged drought translated to moderate drought conditions in the Project area by January 2013, extreme drought conditions by January 2014, and exceptional drought conditions by the end of 2014. The results of fatality monitoring may have been influenced by the three-year drought that the Project site is experiencing. The annual average precipitation at the Project site is 10.11 inches, and the site received 8.44 inches in 2011-2012, 4.01 inches in 2012-2013, and 3.43 inches in 2013-2014 (San Luis Obispo County Public Works 2014). Drought conditions were responsible for low vegetative cover in 2014 at areas within the Project site that had been revegetated, as well as undisturbed reference sites (HTH 2014b). Lower vegetative cover likely resulted in decreased food abundance, and may have contributed to declines in overall avian abundance in the Project vicinity. Therefore, overall fatality counts should be interpreted with caution, as they could differ under non-drought conditions.

4.1.2 Utility of Repeat Searches

Repeat searches were originally designed to capture higher numbers of fatalities, especially taxa like bats that are less likely to leave sign behind after scavenging, and to provide verification of the results found in weekly searches. Because it was not practical to conduct repeat searches for any more than 5% of most arrays and 5% of the fences, repeat data from these small areas sampled from our previous year resulted in large sampling bias when extrapolated to the much larger Project elements. Furthermore, after conducting fatality searches for more than a year, it became apparent that avian fatalities accounted for >99% of all fatality finds, and that a sufficient proportion of fatalities (22.6% of all small carcasses and 63.6% of all large carcasses) persisted past the weekly search interval. Together, these reasons led to the decision to cease repeat searches at the CVSR Project.

Despite our decision to stop repeat searches at CVSR, short-interval searches could potentially play an important role in areas with higher scavenging rates and at sites where a large proportion of animals could be scavenged without leaving sign. Also, at sites with higher rates of fatalities, a lower number of searched trackers may be sufficient for accurately estimating site-wide fatalities. However, this method should be implemented only after assessing fatality rates through reconnaissance searches.

4.1.3 Utility of Incidental Detections

Of the 35 fatalities found during this reporting period, only one was found by CVSR operations staff. Fatalities were rarely found in high-traffic areas such as roads, suggesting that data gathered from future incidental reporting will be very limited for analytical purposes. On their own, incidental detections are unlikely to provide enough data to allow tracking of trends in species found, seasonal variations, or trends across Project elements. Despite this limitation, ongoing reporting of these detections may yet assist in identifying and remediating major wildlife hazards on the Project site. The fatality that was discovered by CVSR Project staff during this reporting period was likely caused by electrocution, highlighting the role of the incidental detection protocol.

4.2 Fatality Trends: Cause of Death by Project Element

4.2.1 Fatalities by Cause of Death

4.2.1.1 Arrays

Among avian species expected to be affected by development of the Project, waterbirds were of particular concern. Because waterbirds are sometimes attracted to black-top parking lots or roads, and some solar facilities have reported finding high proportions of waterbirds (Horvath et al. 2009; Grippo et al. 2014; Kagan et al. 2014), obligate waterbirds could potentially be at risk at and near solar arrays. However, during the current year reporting period, only three waterbirds were detected in arrays at CVSR.

It is difficult to discern if waterbird fatalities were low because waterbirds were less attracted to the region during the drought, the birds didn't perceive the arrays as water, or for some other reason. Extreme drought conditions have led to longer-than-normal dry lake conditions in Soda Lake, approximately 2 miles (3 km) south of the Project site. This dry lake supports standing water only during wet years, when it is a major attractant for waterbirds to the region.

Except for the Evaporation Pond (where several waterbird species have been observed by HTH biologists), the Project site lacks aquatic habitats suitable for waterbirds. Therefore, the three waterbirds likely had confused the arrays for water bodies and either collided with a panel or landed in the array. Pied-billed grebes are obligate waterbirds and have difficulty taking flight from land because of the posterior position of their feet (Miller 1942;

Johnsgard 1987). American coots also spend a majority of their lives in water, but they are also capable of making short-distance movements on land. Considering the life history of these species and the lack of suitable habitat on site, the three fatalities were considered collisions; these individuals may have died from predation after they landed in the arrays and were unable to take off, or died from trauma stemming from collision.

A total of ten carcasses were found in the arrays during this reporting period. Of these, the probable cause of death could be established for only three. Previous studies of birds that have died from window collisions suggest that birds rarely have broken necks or other visible skeletal fractures, but intercranial hemorrhaging is almost always present (Klem 1991). Because we did not perform necropsies on whole carcasses found in the field, we were not able to definitively rule out collision as a possible cause of death. Cause of death determinations are further complicated by the possibility that survivors of collisions may be temporarily stunned, and made more susceptible to predation. Given these factors, the cause of death for whole carcasses found without signs of injury or disease were categorized as unknown.

4.2.1.2 Gen-tie Line and MVOH Line

The majority of fatalities found along the Gen-tie and MVOH Lines were located directly or nearly directly under these lines. This pattern suggests that many of these fatalities were caused by powerline collisions, and that the remains were indicative of scavenging, rather than predation. Brown and Drewien (1995) and many others have documented that high-tension powerlines contribute to avian mortality, and especially to the mortality of larger birds such as waterfowl. However, few large carcasses were detected during fatality searches of the Gen-tie and MVOH Lines. Instead, the majority of fatalities found were passerines, possibly reflecting the greater proportion of passerines that occur on the site. Nevertheless, these results suggest that the avian flight diverters installed on the Gen-tie Line may greatly reduce the risk of collisions with larger birds, but are not effective at diverting smaller birds.

In contrast to the fatalities found along the MVOH Line, fatalities found along the Gen-tie Line showed strong seasonal peaks in fall and late spring. Also, Gen-tie Line fatalities included migrant passerines not typically observed on the Project site or expected in the area. The Gen-tie Line and MVOH Line differ from each other in several respects: the Gen-tie Line follows a large elevational change, the lines are higher above the ground than the MVOH Line, and several bird species breed at a pond with tamarisk trees located directly below the Gen-tie Line. To help determine potential differences in fatality patterns between the two types of overhead lines, we produced graphs relating fatality number and species richness to tower number and elevation. These graphs did not suggest any clear linear trends or clustering near the tamarisk pond; fatalities were more or less equally distributed along the Gen-tie Line. Therefore, the differences in height between these two structures may be the main factor effecting differences in fatality rates and species richness of fatalities. The avian flight diverters on the Gen-tie Line appear to be largely ineffective in deterring these migrant and winter resident passerines, possibly because these birds are less apt to see overhead lines during nocturnal movements.

The tamarisk pond was not searched directly for the full year, to avoid disturbing nesting birds during the breeding season. In the fall, dense saltbush (*Atriplex* sp.) made some areas between the pond and Tower 17 impassable. Although the lack of fatality clustering on towers to either side of the tamarisk pond suggests that the higher avian use at the tamarisk pond does not result in a detectable increase in collision in the vicinity of the pond.

It is difficult to study how the mortality of large and small birds along the overhead lines compares with background mortality rates without having a linear control in the landscape. We know of no studies that control for background mortality rates along a linear corridor without an actual linear structure. Instead, most avian mortality studies of high-tension powerlines typically compare fatality rates of powerlines with or without avian flight-diverting structures (Brown and Drewien 1995; Janss and Ferrer 1998). Given that more passerine fatalities were documented along the CVSR Project powerlines than expected, and very few raptor fatalities were documented, a linear control would be useful in understanding how these fatality rates compare with background fatality rates for large and small avian groups in the Project area.

4.2.1.3 Control Plots

The control plots were designed as a way to quantify background levels of mortality on the Project site. All fatalities found in control plots were assigned an unknown cause of death, and all of these fatalities were included in a total fatality estimate that was used to define an adjustment factor for the site. For other research sites where preconstruction surveys are not a viable option, on-site control plots may provide similar data that could not otherwise be obtained. At CVSR, cause of death could not be determined for most array fatalities, so data from the control plots was useful in elucidating what percentage of array fatalities may be assigned to background (natural) causes, rather than indirect or direct Project-related causes.

4.2.1.4 Evaporation Pond

The Evaporation Pond represented a concern because evaporation ponds in xeric environments can attract birds and exposethem to elevated selenium and toxic salt levels. Additionally, the perimeter fence surrounding the pond was considered to represent a collision risk. However, the Evaporation Pond had the lowest number of fatalities during this reporting period, and all fatalities were found on the same day.

The only bird considered to have died from disease during this reporting period was found along the fence of the Evaporation Pond. Because this bird was extremely emaciated, disease seemed to be the plausible cause of death.

During the entire postconstruction monitoring period, Evaporation Pond levels were relatively low. Nonetheless, passerines and waterbirds were occasionally observed in and around the pond before searchers conducted fatality searches. As part of CVSR operations, a bird deterrence protocol (hazing and use of automated deterrence devices) was in place at the Evaporation Pond throughout the designated shorebird nesting season (February through July). These efforts likely resulted in less use of the pond by birds. Given that so few fatalities were detected at the pond, especially during time periods were active deterrence devices were not in use, risk of fatalities occurring at the pond appears to be low.

4.2.1.5 Fences

Few fatalities were detected along array perimeter fences, and only one was attributed to collision. Given the low number of fatalities found at this Project element, risk of fence collision as a whole appears to be low.

4.3 Fatality Estimates

4.3.1 Estimated Fatalities on the CVSR Project Site

During the period of 7 November 2013 to 6 November 2014 (the period used in the Fatality Estimator), there were an estimated 126 fatalities from known causes that occurred on the Project site (90% confidence interval: 106–155).

There were an estimated 2.24 fatalities per tracker (90% confidence interval: 1.83–2.87) from unknown or natural causes of death in the arrays. In control plots, there were an estimated 1.72 fatalities per control plot (90% confidence interval: 1.05–2.68). The confidence intervals for controls are considerably wider in part because fewer trackers were searched in control areas than in array areas for the year.

The confidence interval is much smaller this year, compared to the confidence interval of 3.09 fatalities per tracker reported last year, when we provided a fatality estimate for just Array 1 from nearly 1 year of data. Because we grouped all of the arrays' data, thus creating a larger sample size for a single fatality estimate, we more accurately estimated a fatality rate for the site as a whole. Additionally, by combining 2 years of carcass-persistence and searcher-efficiency data, we decreased the amount of uncertainty in our modeling parameters, which in turn decreased the amount of uncertainty in the fatality estimate as a whole.

Large-scale fatality searches at solar facilities have been a subject of interest since as early as the 1980s (e.g., Wagner et al. 1983), but the methods still vary in search intensity and regularity, fatality estimation methods used, and methods used for determining cause of death (e.g., Althouse and Meade 2014; HTH 2014a). Because of the differences among studies, comparison among rates of fatalities reported remains difficult. Although fatality rates per megawatt are often reported as a useful tool to compare rates among industrial sites and across energy types (Arnett et al. 2008; Smallwood 2013), it is easy to draw incorrect conclusions if the underlying methods differ and if different panel technologies are involved (e.g., a tracker unit generating 0.5 megawatts more than an alternative type may only be 7% larger).

4.3.2 Adjusting Fatality Rates on the CVSR Project Site

Observed fatalities within arrays that could be attributed to collision were limited (N=6 in 2013-2014); thus, fatality estimates at CVSR are primarily based upon fatalities where the cause of death or injury could not be determined. Adjusting these avian fatality rates by background fatality rates measured within control plots substantially reduced the estimated fatality rate that may be related to the CVSR Project. Whether placed within the context of per-acre of arrays or per-acre of tracker units, an annual mean background-adjusted fatality estimate of 526 fatalities indicates that there may be one fatality per 2.3 acres per year that cannot currently be explained by background fatality rates as measured in control plots.. These could be fatalities resulting from collision that leave no evidence of collision (or are moved away from the site of collision by scavengers), or increased fatality rates due to differential rates of avian use and/or predation within the arrays compared to the control plots.

We observed an increase of some avian species within the arrays. Mourning doves were the most common fatality in solar arrays, followed by horned larks and house finches, which combined accounted for 66% of all fatalities. During the first year of study, there were 44 point count detections of seven species perched on the developing arrays of solar panels. After the second year of study, the numbers had increased to 210 total detections of 13 species, including a merlin (*Falco columbarius*). After the third year of study, the numbers had increased to 578 total detections of 15 species; however, 81% of the tally consisted of house finches and mourning doves. Observations of horned larks during avian use surveys averaged higher in the array and Gen-tie survey areas than in the offsite survey areas throughout the study period, especially in winter (HTH 2015).

Modeling results indicated that activity rates for mourning doves increased in construction areas and remained high as the Project moved into the operational phase, suggesting a lasting attraction for these species (HTH 2015). Ninety-nine percent of the observations of mourning doves within the solar generation facility occurred in the arrays, either on the ground or perched on array structures (HTH 2015). Mourning doves are among the most widespread and abundant species in the country; Seamans and Sanders (2014) estimated that there are approximately 275 million mourning doves in the country, and their abundance appears to be stable in the West.

Surveyors at the CVSR Project documented use by scavenger/ predatory birds and mammals (San Joaquin kit fox [*Vulpes macrotis mutica*] and coyote [*Canis latrans*]). A merlin was observed perching and hunting in the developed solar arrays; also observed were a foraging red-tailed hawk and a foraging ferruginous hawk (*Buteo regalis*). Merlins eat mostly sparrow-sized to dove-sized birds (Warkentin et al. 2005) often specializing on hunting a couple of the most abundant species in an area, which would include horned larks, house finches, and mourning doves in the Project area. Each merlin can prey on 2.2 to 2.5 birds per day (Page and Whitacre 1975; Warkentin et al. 2005). They are known to flush flocks to take advantage of the confusion, which surveyors at CVSR have hypothesized may result in strikes with array infrastructure. Differential use of the arrays by avian species combined with predation by raptors, foxes, and coyotes could explain the current estimated difference between fatality rates within arrays and control plots.

We should point out that the sample size for control plots is low, and the number of fatalities within those control plots is even lower. Low sample size can easily lead to biases due to sampling error. Conducting bootstrap analysis on observed data inherently invokes an assumption that the observed data adequately represents the true state of the system. For example, in this case we must assume that the 14 fatalities detected in the 30 control plots (for the 2013/14 survey period) adequately represent fatality rates across all onsite Conservation Lands. Since the 30 control plots only cover a very small fraction of Conservation Lands, this assumption is tenuous. Furthermore, even though N_C trackers are sampled for each bootstrap iteration, they are drawn from the much larger N_T "population" of surveyed trackers (which represents approximately 20% of all trackers). As a result, we effectively sampled a large portion of the total number of trackers over the many bootstrap iterations, but the area over which we sampled control plots remains fixed and small. Therefore, some bias and imbalance remains in the bootstrapped results. We believe that these methods make the best use of the available data to control for background fatality in estimating fatality rates attributable to the CVSR Project and quantifying the uncertainty in those estimates.

In addition to the imbalance in sample area between control and array plots, there are several other factors that may influence these results. The proximity of control plots to arrays should be advantageous because we are comparing similar underlying habitats. However it is possible that fatality rates in lands immediately adjacent to the Project could be affected by their proximity to the Project, and thus would not adequately represent the background fatality rate of the area if the Project was absent all together. The large difference in estimated fatality rates between this year, and the 2013 annual report likely represents a reduction in avian use as continued drought widely impacted bird populations and nesting behavior (Section 4.1.1). Noting this difference among years stresses the importance of comparing fatality rates during the same time periods over successive years, because changes in bird population abundance and behavior may greatly affect analysis results.

More research is needed to address the issue of background fatality rates versus fatality rates attributable to solar photovoltaic projects. Study designs that include avian use studies within arrays and control plots, and studies that balance sample sizes within arrays and control plots would address many of the limitations of this analysis.

4.3.3 Carcass-persistence Rates

Although previous studies have monitored the overall persistence of carcass sign (e.g., feather spots), the practice has not been universally adopted (Balcomb 1986; Hager et al. 2012). Nevertheless, we chose to focus on overall persistence times, rather than time to scavenging alone, because feather spots represent an important source of data for fatality searches. Although some information is lost after scavenging, feather spots may still provide some degree of certainty about cause of death, by their location (e.g., directly under a powerline) and species identification (e.g., feather spots from waterbirds species may lend credibility to the idea that individuals of the species mistake the arrays for water). The results of our carcass-persistence trials revealed that, whereas average scavenging times were less than a week for both small and large carcasses across seasons, average persistence times ranged from 5 days to 30 days. The results also suggest that, although season has a strong influence on scavenging time, it has considerably less influence on overall persistence time. Instead, size seems to have a strong impact on persistence time: small carcasses are much more likely to be removed completely during scavenging, whereas large carcasses tend to leave feather spots behind.

In our study, we were careful to avoid scavenger swamping. Although some previous studies (e.g., Wagner et al. 1983, Ponce et al. 2010, and Derby et al. 2007) likely overloaded the capacity of local scavengers to effectively dispose of placed carcasses (Smallwood et al. 2010), the smaller numbers of carcasses we placed each week helped to ensure that we recorded accurate scavenging times. Still, several carcasses were visited several times before they were scavenged. Kit foxes are one of the few scavenger species present in the area that is capable of food caching (Clark pers. comm.), but they too sometimes visited carcasses without attempting to remove them. Because we made a concerted effort to use fresh carcasses, we feel that this pattern simply highlights the highly opportunistic nature of scavenging.

Our results suggest that, although scavenging times may differ by 1–2 days by season, persistence time of feather spots is most affected by the vegetation height and density where the carcass is placed. Although this may seem self-evident, the effects of vegetation height on carcass persistence has received limited attention in previous studies of carcass persistence or fatality estimates, and it may have significant implications for fatality estimates at sites where ground vegetation is cleared or purposely kept short, particularly when search intervals are longer than a week.

4.3.4 Searcher-efficiency Rates

Overall searcher-efficiency rates between 2012 and 2014 were comparable to efficiency rates at other wind and solar energy facilities, where rates have ranged from 32% to 67% (Nicholson et al. 2005; Derby et al. 2007; Leslie et al. 2012; Johnston et al. 2013; Martin et al. 2013).

Our study incorporated feather spots along with carcasses in the searcher-efficiency trial design. Feather spots are rarely incorporated into fatality studies, but many fatality studies report a majority of fatalities from feather spots (Derby et al. 2007; WEST 2004; Johnston et al. 2013; Martin et al. 2013; Althouse and Meade 2014), either because scavenging is rapid or because there are longer search intervals. Thus, visibility associated with the condition of the fatality is rarely representative of true conditions and could affect fatality estimates. In our study, fatality searchers were most effective at finding large carcasses and large feather spots in easy visibility conditions, and least effective at finding small feather spots in both easy and moderate visibility conditions, and at finding small carcasses in moderate visibility conditions. When attempting to recover a missed trial specimen in one of the latter three classes, and even when standing within a few feet of the specimen, searchers often had difficulty visually locating it. Undoubtedly, these fatality types were difficult to detect because they blend in with vegetation, even when vegetation height is low. The large differences in detectability between carcasses and feather spots point to the importance of incorporating feather spots into studies, to yield more robust fatality estimates.

Section 5.0 Recommendations

During the course of this fatality monitoring study, we have identified areas where further research is needed to guide the design of future fatality monitoring studies at utility-scale solar facilities. The following recommendations outline research areas and measures that we believe are important.

- Projects covering large amounts of area may have a significant portion of fatalities from natural background mortality. To determine the contribution of background mortality, a spatially balanced study employing control plots similar in size, layout, and overall total area, should be used to estimate background fatality rates with comparable accuracy to the developed project site.

- Focused research on the causes of feather spots and the average number of feather spots created from a single fatality should be considered.

- If site-wide fatality monitoring is deemed necessary and the primary goal is to determine annual operational fatality rates, then site-wide fatality monitoring should be started once the full project becomes operational and for at least one year. Fatality searches phased in as portions of the project become operational can be used to document fatalities prior to site-wide searches, and to conduct searcher efficiency and carcass persistence trials to develop the survey design. Fatality monitoring survey design, including spatial coverage requirements and survey frequency can be optimized after the collection of preliminary data.

- Intensive daily repeat fatality surveys are not necessary to conduct fatality estimates. The reduced spatial and temporal coverage of these intensive surveys may lead to less precise estimates when extrapolated to obtain site-wide annual estimates, and are only recommended when required to link timing of fatalities to specific events (e.g., weather patterns or operational changes).

- Avian use studies should consider bird census techniques that are potentially more effective in documenting species richness and relative abundance of birds in project areas that will be covered by arrays. Typical point count study designs may not be effective at detecting birds that tend to remain concealed under panels during counts. Line transect methods may provide a better index of avian use before and after construction. Birds under panels will likely be more visible from line transects oriented perpendicular to the array tracker rows than they would be from fixed-location point count sites located outside the arrays. If possible, line transect survey intervals should mirror fatality search intervals, to assess whether fatality rates correspond with bird activity levels. If survey intervals cannot mirror fatality search intervals, we recommend a minimum of monthly avian activity searches using line transects to determine relative abundance and trends in populations during periods of avian fatality monitoring.

- Projects incorporating high-tension powerlines should assess whether the project site is located in an important route for migratory songbirds. Because many migratory songbirds fly at night, typical deterrence devices that have been successful with raptors may not be as effective at preventing collisions by songbirds.

- To assess fatalities along linear project features such as powerlines, study designs should incorporate linear controls, to provide background mortality rates for such features.

- To the extent practicable, powerlines should not be placed over wetland features, where large numbers of birds may roost and nest. Wetland features, such as the tamarisk wetland along the Gen-tie Line, provide habitat for common and sensitive species, such as the tricolored blackbird (*Agelaius tricolor*), now emergency-listed under the California Endangered Species Act.

- We recommend that necropsies be performed on a subset of carcasses when practicable, especially when external injuries are not present; birds that have died because of collisions may not have external signs of injury, but typically exhibit intercranial hemorrhaging that can be identified during a necropsy. Performing necropsies on a subsample of carcasses may lead to more information about the cause of death.

- The use of scent dogs in fatality monitoring efforts should be considered to increase the accuracy and narrow the confidence level of fatality estimates, especially in areas with high density vegetation. Scent dogs have been shown to be more efficient at detecting some fatality classes than human searchers and have a higher likelihood of detecting rare events than humans, given equal levels of survey effort (HTH, unpublished data). Studies on sites with varying topography, complex habitat features, and dense vegetation may benefit from scent dog searches because the dogs rely on olfactory, rather than visual, cues.

- Feather spots should be incorporated into bias-trial protocols to produce more robust fatality estimates and to provide more comparable industry-wide fatality estimates, especially for studies with longer search intervals.

Appendix A. Avian Species Used in Searcher-efficiency Trials, September 2012 to November 2014 (N = 434)

Species	Carcass Size	Number of Fatality Plants Placed[1]
Acorn woodpecker (*Melanerpes formicivorus*)	Large	1[2]
America coot (*Fulica americana*)	Large	9
American crow (*Corvus brachyrhynchos*)	Large	11
American kestrel (*Falco sparverius*)	Large	1
Band-tailed pigeon (*Patagioenas fasciata*)	Large	6
Barn owl (*Tyto alba*)	Large	5
Black-crowned night heron (*Nycticorax nycticorax*)	Large	1
Black-headed grosbeak (*Pheucticus melanocephalus*)	Small	1
Brewer's blackbird (*Euphagus cyanocephalus*)	Small	4
Brown-headed cowbird (*Molothrus ater*)	Small	6
Burrowing owl (*Athene cunicularia*)	Large	1
California quail (*Callipepla californica*)	Large	12
California towhee (*Melozone crissalis*)	Small	1
Cedar waxwing (*Bombycilla cedrorum*)	Small	1
Chestnut-backed chickadee (*Poecile rufescens*)	Small	1
Cliff swallow (*Petrochelidon pyrrhonota*)	Small	8[2]
Common raven (*Corvus corax*)	Large	16
Common yellowthroat (*Geothylpis trichas*)	Small	1
Cooper's hawk (*Accipiter cooperii*)	Large	12
Eared grebe (*Podiceps nigricollis*)	Large	1
Eurasian collared-dove (*Streptopelia decaocto*)	Large	7
European starling (*Sturnus vulgaris*)	Small	2
Great horned owl (*Bubo virginianus*)	Large	16
Greater roadrunner (*Geococcyx californianus*)	Large	4
Green heron (*Butorides virescens*)	Large	2
Horned lark (*Eremophila alpestris*)	Small	36
House finch (*Carpodacus mexicanus*)	Small	53
House sparrow (*Passer domesticus*)	Small	17
Lark sparrow (*Chondestes grammacus*)	Small	2
Lesser goldfinch (*Spinus psaltria*)	Small	1
Lincoln sparrow (*Melospiza lincolnii*)	Small	3
Long-eared owl (*Asio otus*)	Large	3
Mourning dove (*Zenaida macroura*)	Large	70
Red-shouldered hawk (Buteo lineatus)	Large	30[2]
Red-tailed hawk (*Buteo jamaicensis*)	Large	2
Rock pigeon (*Columba livia*)	Large	15

Species	Carcass Size	Number of Fatality Plants Placed[1]
Savannah sparrow (*Passerculus sandwichensis*)	Small	7
Sharp-shinned hawk (*Accipiter striatus*)	Large	1
Short-eared owl (*Asio flammeus*)	Large	1
Swainson's thrush (*Catharus ustulatus*)	Small	2
Unknown small	Small	3
Unknown large	Large	1
Unknown raptor	Large	3
Unknown songbird	Small	3
Varied thrush (*Ixoreus naevius*)	Small	1
Warbling vireo (*Vireo gilvus*)	Small	1
Western meadowlark (*Sturnella neglecta*)	Small	25
Western scrub-jay (*Aphelocoma californica*)	Small	2
White-crowned sparrow	Small	2
White-tailed kite (*Elanus leucurus*)	Large	1
Yellow warbler (*Setophaga petechia*)	Small	9
Yellow-billed magpie (*Pica nuttalli*)	Large	7
Yellow-rumped warbler (*Dendroica coronata*)	Small	3

Acorn woodpecker (*Melanerpes formicivorus*)	Small	6
American coot (*Fulica americana*)	Large	4
American crow (*Corvus brachyrhynchos*)	Large	18†
American goldfinch (*Spinus tristis*)	Small	2
American kestrel (*Falco sparverius*)	Large	3
American robin (*Turdus migratorius*)	Large	3
Anna's hummingbird (*Calypte anna*)	Small	3
Band-tailed pigeon (*Patagioenas fasciata*)	Large	3†
Barn owl (*Tyto alba*)	Large	5†
Black turnstone (*Arenaria melanocephala*)	Large	1
Brewer's blackbird (*Euphagus cyanocephalus*)	Small	6
Blackbird sp.	Small	1
Bullock's oriole (*Icterus bullockii*)	Small	1
Bushtit (*Psaltriparus minimus*)	Small	2
California gull (*Larus californicus*)	Large	1
California thrasher (*Toxostoma redivivum*)	Small	1
California quail (*Callipepla californica*)	Large	2*
California towhee (*Melozone crissalis*)	Small	4
Cedar waxwing (*Bombycilla cedrorum*)	Small	2
Cliff swallow (*Petrochelidon pyrrhonota*)	Small	4
Common raven (*Corvus corax*)	Large	2
Cooper's hawk (*Accipiter cooperii*)	Large	1
Eurasian collared-dove (*Streptopelia decaocto*)	Large	7
European starling (*Sturnus vulgaris*)	Small	4
Great horned owl (*Bubo virginianus*)	Large	9
Greater roadrunner (*Geococcyx californianus*)	Large	2
Hermit thrush (*Catharus guttatus*)	Small	1
Horned grebe (*Podiceps auritus*)	Large	2
Horned lark (*Eremophila alpestris*)	Small	3
House finch (*Haemorhous mexicanus*)	Small	16
House sparrow (*Passer domesticus*)	Small	6†
House wren (*Troglodytes aedon*)	Small	2
Lesser goldfinch (*Spinus psaltria*)	Small	2
Lincoln's sparrow (*Melospiza lincolnii*)	Small	1
Mourning dove (*Zenaida macroura*)	Large	11*
Northern flicker (*Colaptes auratus*)	Large	2
Northern fulmar (*Fulmarus glacialis*)	Large	1
Northern mockingbird (*Mimus polyglottos*)	Small	5

Species	Carcass Size	Number Placed
Nuttall's woodpecker (*Picoides nuttallii*)	Small	3
Peregrine falcon (*Falco peregrinus*)	Large	1
Pine siskin (*Spinus pinus*)	Small	1
Red-necked phalarope (*Phalaropus lobatus*)	Small	1†
Red-shouldered hawk (*Buteo lineatus*)	Large	7†
Red-tailed hawk (*Buteo jamaicensis)*	Large	9†
Red-winged blackbird (*Agelaius phoeniceus*)	Small	2
Rock dove/pigeon (*Columba livia*)	Large	4
Ruby-crowned kinglet (*Regulus calendulai*)	Small	1
Savannah sparrow (*Passerculus sandwichensis*)	Small	2
Sharp-shinned hawk (*Accipiter striatus*)	Large	1†
Song sparrow (*Melospiza melodia*)	Small	1
Western bluebird (*Sialia mexicana*)	Small	1
Western meadowlark (*Sturnella neglecta*)	Large	1
Western screech-owl (*Megascops kennicottii*)	Large	5
Western scrub-jay (*Aphelocoma californica*)	Small	9
White-crowned sparrow (*Zonotrichia leucophrys*)	Small	4
White-tailed kite (*Elanus leucurus*)	Large	2†
Yellow-rumped warbler (*Setophaga coronata*)	Small	2

Notes:
* = Reclassified:
- One California quail was a nestling and was classified as a small carcass.
- Two mourning doves were juveniles and were classified as small carcasses.

† Excluded from analysis:
- Two American crows were excluded from analysis because full persistence data were lacking.
- One band-tailed pigeon was excluded from analysis because full persistence data were lacking.
- One barn owl was excluded from analysis because full persistence data were lacking.
- One house sparrow was excluded from analysis due to removal by biologist prior to scavenging.
- One red-necked phalarope was excluded from analysis due to camera malfunctioning.
- One red-shouldered hawk was excluded from analysis because full persistence data were lacking.
- Two red-tailed hawks were excluded from analysis because full persistence data were lacking.
- One sharp-shinned hawk was excluded from analysis because full persistence data were lacking.
- One white-tailed kite was excluded from analysis because full persistence data were lacking.

Appendix C. Weekly Fatality Search Results: 16 August 2013 to 17 November 2014

Incident ID	Site	Search Date	AOU Code[1]	Observation Details	Cause of Death[2]	% Certainty	UTM Zone	Easting	Northing
20130828-41	34.5kV Line	8/28/2013	UNWA	Feather spot: 16 primaries and secondaries, four tail, and 40+ contour feathers from unknown warbler.	C	>50	11S	236786	3913033

20140410-21	Array 7	4/10/2014	PBGR	Feather spot: Approximately 500 body feathers and 30 flight feathers with fresh blood. Coyote observed consuming bird in morning. Unclear if predation or scavenging event; however, it was determined that the death was indirectly caused by the array, because the grebe likely perceived the array as a body of water, and once it landed on the ground was unable to take flight again. Subject: **Notification of Avian Fatality in Compliance with Condition of Approval #44 of the Conditional Use Permit (DRC 2008-00097) for the California Valley Solar Ranch, San Luis Obispo California**

Dear Mr. Sloan, Mr. Hacker, and Mr. McKenzie:

As per Condition of Approval #44 of the Conditional Use Permit (CUP; DRC 2008-00097) for the California Valley Solar Ranch (CVSR) project, a Brine Evaporation Pond Design, Monitoring, and Management Plan (BEPMMP) was developed that details the design and function of the evaporation pond, and includes measures to monitor and report bird fatalities detected at the pond. Reporting measure 9.2 of the BEPMMP requires that a biologist notify the California Department of Fish and Wildlife (CDFW), the U. S. Fish and Wildlife Service (USFWS), San Luis Obispo County (County), and the County's Environmental Monitor within 2 days of discovering a carcass if dead or entangled birds are detected at the pond.

On 24 December 2013, I was informed that H. T. Harvey & Associates Field Biologist, Melinda Mohamed, observed four avian fatalities, three house finches (*Haemorhous mexicanus*) and 1 mourning dove (*Zenaida macroura*) at the CVSR Brine Evaporation Pond on 23 December 2013 (Figure 1). Two of the house finches and the mourning dove fatalities were observed as feather spots and the remaining house finch was observed intact. The three feather spots represent birds that were likely attracted to the pond area for drinking water that were subsequently preyed upon by raptorial predators. The cause of death for the intact house finch is unknown and may be different from the other fatalities. I have included the data for each of the four fatalities on the ensuing two pages of this notification.

Feel welcome to contact me with questions if you require further information regarding this notification.

Sincerely,

Brian B. Boroski, Ph.D., *agent on behalf of High Plains Ranch II, LLC*
Vice President

Data for the four avian fatalities found on 23 December 2013 at the Brine Evaporation Pond at CVSR

Incident 20131223-36:

Species: HOFI

Parts found: 100+ body feathers, ~20 flight feathers (including partial wing)

Cause of death: unknown

Scavenger/predator type: unknown

Estimated time since death: <1 week—high visibility of featherspot on bare ground make it unlikely the spot was missed during the last weekly survey

Additional notes: spread was large—body feathers blown by high wind, but flight feathers were mostly clumped

UTM: 11S 0234781 3914267

Incident 20131223-58:

Species: MODO

Parts found: tail segment (majority, 10 flight and 8 body feathers)

Cause of death: unknown

Scavenger/predator type: unknown

Estimated time since death: <1 week (default)

Additional notes: outside evaporation pond

UTM: 11S 0234676 3914214

Incident 20131223-16:

Species: HOFI

Parts found: whole carcass

Cause of death: unknown

Scavenger/predator type: unknown

Estimated time since death: <24 hours—dirt stuck in blood around mouth is still moist

Additional notes: No rigor mortis, malnourished, can feel keel; feathers around cloaca are matted with feces, dried blood around edges of beak

UTM: 11S 0234809 3914200

Incident 20131223-57:

Species: HOFI

Parts found: 10+ body feathers, 1 flight feather

Cause of death: unknown

Scavenger/predator type: unknown

Estimated time since death: <1 week—assuming would have been found last week and feathers would have blown away.

Additional notes:

UTM: 11S 0234798 3914194

Subject: California Valley Solar Ranch Project Avian Bat Protection Plan Quarterly Avian Fatality Report (Aug-Nov 2013)

Dear Sirs:

On behalf of High Plains Ranch II LLC, we are submitting the Quarterly Avian Fatality Report (Aug-Nov 2013) for the California Valley Solar Ranch (CVSR) Project, San Luis Obispo, California. This report is being submitted per the reporting requirements of the CVSR Avian Bat Protection Plan in compliance with the U.S. Fish and Wildlife Service Biological Opinion (81420-2011-F-0511) and San Luis Obispo County Conditional Use Permit (DRC2008-00097) for the CVSR Project. San Luis Obispo County Condition of Approval #58 requires an Avian Fatality Monitoring Plan for the Project as part of the Avian Bat Protection Plan, which requires quarterly reports detailing any project-related bird deaths or injuries detected during the monitoring study. As required to satisfy COA #58, of the CVSR Project Conditional Use Permit, we are submitting these reports to the County, U.S. Fish and Wildlife Service, and California Department of Fish and Wildlife.

If you should have any questions or comments, please do not hesitate to contact me at (408) 426-7326 or jklingmann@harveyecology.com.

Sincerely,

Julie Klingmann
Associate, Senior Wildlife Ecologist

Memorandum

12 January 2015 **Project #3326-03**

To: **Erin Dean, Office of Law Enforcement (OLE) Resident Agent in Charge (RAC), U.S. Fish and Wildlife Service (USFWS)**
Heather Beeler, Regional Migratory Bird Permit Office (RMBPO), USFWS
Kenneth Sanchez, Assistant Field Supervisor, Endangered Species Program, USFWS
Dave Hacker, California Department of Fish and Wildlife (CDFW) Manager, CDFW Region 4 Renewable Energy Projects

From: **Brian Boroski, Dave Johnston, and Doug Drynan, H. T. Harvey & Associates (HTH)**

Subject: **Fourth quarter and 2014 annual report of avian mortality and injury, as per migratory bird Special Purpose Utility (SPUT) salvage permit (MB02733B-0) for the California Valley Solar Ranch (CVSR)**

As per Condition E of the CVSR SPUT permit (MB02733B-0), we are submitting an annual report of avian mortality and injury for 2014. The annual report submission deadline overlaps with reporting requirements for the fourth quarterly report; therefore, this submission also serves as the quarterly report of avian mortality and injury for the fourth quarter (October through the end of December). Data were collected for each fatality (i.e. carcass, partial carcass, or feather spot) and injury detected during regular fatality surveys of the CVSR site. As of mid-November 2014, the systematic fatality monitoring program as outlined in the Avian and Bat Fatality Monitoring Plan for the CVSR Project was completed. Any subsequent reporting of avian mortality from that point forward will be from incidental observations by CVSR staff.

Data from fatality detections were entered in the spreadsheet database that USFWS supplied with the SPUT permit. An electronic version of this spreadsheet has been sent to each recipient listed above. With this annual report we are also attaching a summary of data omissions and changes that were noted after the quarterly reports had been submitted (Table 1, attached).

Table 1. California Valley Solar Ranch Project 2014 SPUT Annual Report documentation of 2014 database changes and additions[1].

Specimen Number	Discovery Date	Species Common Name	Scientific Name	Transect/Subplot Number	Notes on Changes and Additions
20140107-91	1/7/2014	Western meadowlark	*Sturnella neglecta*	Control 2C-5	Latitude and Longitude coordinates incorrect. Updated coordinates to Lat: 35.33714704, Long: -119.9228773.
20140108-126	1/8/2014	Mourning dove	*Zenaida macroura*	MVOH Line	Distance to Project Feature should have been included. Added distance and changed Cause of Death % certainty to >50%, since fatality is within 10 feet of line.
20140108-102	1/8/2014	Western meadowlark	*Sturnella neglecta*	Gen-Tie Line	Distance to Project Feature should have been included. Added distance and changed Cause of Death % certainty to >50%, since fatality is within 10 feet of line.
20140121-111	1/21/2014	Eurasian collared dove	*Streptopelia decaocto*	Array 1-2 Fence	Distance & Azimuth to Project Feature should have been included. Added Distance of 0 feet and Direction as NA.
20140122-94	1/22/2014	Mourning dove	*Zenaida macroura*	Array 4 Fence	Distance & Azimuth to Project Feature should have been included. Added Distance of 0 feet and Direction as NA.
20140122-37	1/22/2014	Unknown raptor	*NA*	MVOH Line	Distance to Project Feature should have been included. Added distance of 13 feet.
20140122-38	1/22/2014	House finch	*Carpodacus mexicanus*	MVOH Line	Distance to Project Feature should have been included. Added distance of 13 feet.
20140122-16	1/22/2014	Western meadowlark	*Sturnella neglecta*	Gen-Tie Line	Distance to Project Feature should have been included. Added distance and changed Cause of Death % certainty to >50%, since fatality is within 10 feet of line.

---

[1] All changes noted in this table are also highlighted in yellow in the attached 2014 SPUT spreadsheet database.

Specimen Number	Discovery Date	Species Common Name	Scientific Name	Transect/Subplot Number	Notes on Changes and Additions
20140128-21	1/28/2014	House finch	*Carpodacus mexicanus*	Array 1-2 Fence	Distance & Azimuth to Project Feature should have been included. Added Distance of 5 feet and Direction east.
20140129-82	1/29/2014	Unknown large bird	*NA*	Array 4 Fence	Distance & Azimuth to Project Feature should have been included. Added Distance of 0 feet and Direction NA.
20140129-111	1/29/2014	Horned lark	*Eremophila alpestris*	Gen-Tie Line	Distance to Project Feature should have been included. Added distance and changed Cause of Death % certainty to >50%, since fatality is within 10 feet of line.
20140224-67	2/24/2014	Mourning dove	*Zenaida macroura*	Array 8 Fence	Distance & Azimuth to Project Feature should have been included. Added Distance of 3.2 feet and Direction east.
20140312-101	3/12/2014	Common raven	*Corvus corax*	MVOH Line	Distance to Project Feature should have been included. Added distance and changed Cause of Death % certainty to >50%, since fatality is within 10 feet of line.
20140312-36	3/12/2014	Horned lark	*Eremophila alpestris*	Gen-Tie Line	Distance to Project Feature should have been included. Added distance and changed Cause of Death % certainty to >50%, since fatality is within 10 feet of line.
20140313-11	3/13/2014	Horned lark	*Eremophila alpestris*	Array 1	Accidental omission from 2014 Q1 report.
20140317-36	3/17/2014	House finch	*Carpodacus mexicanus*	Array 8 Circuit 2	Changed Cause of Death % Certainty from >50% to >90% based on re-evaluation of specimen and beak injury.
20140326-201	3/26/2014	House finch	*Carpodacus mexicanus*	Along Fence surrounding substation	Distance & Azimuth to Project Feature should have been included. Added Distance of 0 feet and Direction NA.

Specimen Number	Discovery Date	Species Common Name	Scientific Name	Transect/Subplot Number	Notes on Changes and Additions
20140403-51	4/3/2014	Mourning dove	*Zenaida macroura*	Array 9 Fence	Distance & Azimuth to Project Feature should have been included. Added Distance of 0 feet and Direction NA.
20140409-56	4/9/2014	Mourning dove	*Zenaida macroura*	MVOH Line	Distance to Project Feature is 2 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140410-21	4/10/2014	Pied-billed grebe	*Podilymbus podiceps*	Array 7	Cause of Death originally noted as Unknown. Changed Cause of Death to Panel Collision with <50% Certainty.
20140410-101	4/10/2014	Horned lark	*Eremophila alpestris*	Array 7 Fence	Distance & Azimuth to Project Feature should have been included. Added Distance of 0 feet and Direction NA.
20140423-101	4/23/2014	Common raven	*Corvus corax*	MVOH Line	Distance to Project Feature is 5 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140423-102	4/23/2014	Common raven	*Corvus corax*	MVOH Line	Distance to Project Feature is 0 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140423-36	4/23/2014	Rock pigeon	*Columba livia*	MVOH Line	Distance to Project Feature is 3 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140430-56	4/30/2014	Mourning dove	*Zenaida macroura*	MVOH Line	Distance to Project Feature is 6 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140430-101	4/30/2014	Mourning dove	*Zenaida macroura*	Gen-Tie Line	Distance to Project Feature is 0 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.

Specimen Number	Discovery Date	Species Common Name	Scientific Name	Transect/Subplot Number	Notes on Changes and Additions
20140430-36	4/30/2014	Mourning dove	*Zenaida macroura*	Gen-Tie Line	Distance to Project Feature is 2 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140514-93	5/14/2014	Common yellowthroat	*Geothlypis trichas*	Gen-Tie Line	Distance to Project Feature is 10 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140521-41	5/21/2014	Mourning dove	*Zenaida macroura*	Gen-Tie Line	Distance to Project Feature is 0 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140521-42	5/21/2014	Orange-crowned warbler	*Vermivora celata*	Gen-Tie Line	Distance to Project Feature is 10 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140521-43	5/21/2014	Common yellowthroat	*Geothlypis trichas*	Gen-Tie Line	Distance to Project Feature is 0 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140528-57	5/28/2014	Yellow warbler	*Dendroica petechia*	Gen-Tie Line	Distance to Project Feature is 0 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140618-12	6/18/2014	Mourning dove	*Zenaida macroura*	Gen-Tie Line	Distance to Project Feature is 0 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.
20140723-21	7/23/2014	House sparrow	*Passer domesticus*	MVOH Line	Distance to Project Feature was not included. Added Distance of 0 feet.
20140730-21	7/30/2014	Eurasian collared dove	*Streptopelia decaocto*	MVOH Line	Distance to Project Feature was not included. Distance to Project Feature is 0 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.

Specimen Number	Discovery Date	Species Common Name	Scientific Name	Transect/Subplot Number	Notes on Changes and Additions
20140730-41	7/30/2014	Rock pigeon	*Columba livia*	Gen-Tie Line	Distance to Project Feature was not included. Distance to Project Feature is 0 feet off line. Changed Cause of Death % certainty to >50% since fatality is within 10 feet of line.

Memorandum

---

15 July 2014 **Project #3326-03**

To: **Erin Dean, Office of Law Enforcement (OLE) Resident Agent in Charge (RAC), U.S. Fish and Wildlife Service (USFWS)**
Heather Beeler, Regional Migratory Bird Permit Office (RMBPO), USFWS
Kenneth Sanchez, USFWS
Dave Hacker, California Department of Fish and Wildlife (CDFW) Manager, CDFW Region 4 Renewable Energy Projects

From: **Brian Boroski, Dave Johnston, and Doug Drynan, H. T. Harvey & Associates (HTH)**

Subject: **Quarterly report of avian mortality and injury, as per migratory bird Special Purpose Utility (SPUT) salvage permit (MB02733B-0) for the California Valley Solar Ranch (CVSR)**

As per Condition E of the CVSR SPUT permit (MB02733B-0), we are submitting a quarterly report of avian mortality and injury for the second quarter of 2014 (April through the end of June). Data were collected for each fatality and injury detected during regular fatality surveys of the CVSR site. These data were entered in the spreadsheet database that USFWS supplied with the SPUT permit. An electronic version of this spreadsheet has been sent to each recipient listed above. Condition H(1)(a) of the permit requires that a hardcopy version be mailed to the Region 6 CDFW Regional Manager. At the direction of Mr. Dave Hacker, the CDFW Region 4 Renewable Energy Projects contact, all future correspondence and reporting relating to this permit should also be sent to him. He also indicated that it was not necessary to send CDFW hardcopy versions of the spreadsheet, and that electronic submission of reports was sufficient.

As requested, with this 2nd quarterly report, we have attached historical fatality data from 2012 and 2013, in the USFWS spreadsheet database format, for your records. These data have been summarized and presented in the reports required by the Avian and Bat Protection Plan for the CVSR Project.

Certification: I certify that the information in this report is true and correct to the best of my knowledge. I understand that any false statement herein may subject me to criminal penalties under 18 USC 1001.

Section 1.0 Introduction

Through adoption of Resolution #2011-119, the Board of Supervisors of San Luis Obispo County (the County) approved the California Valley Solar Ranch Project (CVSR Project) Conditional Use Permit (DRC 2008-00097) on 19 April 2011. The Conditional Use Permit is subject to the Conditions of Approval (COAs) set forth in Exhibit 6 attached to the Resolution.

The Conditional Use Permit allows High Plains Ranch II, LLC (and any successor in interest for the life of the CVSR Project) to construct and operate a 250-megawatt photovoltaic solar power plant within an approximately 4685-acre site (Project site), located mostly south of State Route (SR) 58, about 6.4 kilometers (km) east of Soda Lake Road, immediately north of the California Valley subdivision, in the Shandon-Carrizo planning area of San Luis Obispo County (Figure 1).

COA #58 of the Conditional Use Permit requires an Avian and Bat Protection Plan (ABPP) and a quarterly report detailing any Project-related bird or bat deaths or injuries detected during the monitoring study defined in COA #58c. To satisfy COA #58c, H. T. Harvey & Associates (HTH), on behalf of High Plains Ranch II, LLC, has prepared this postconstruction fatality report, which documents the number of avian and bat fatalities counted during Project postconstruction monitoring between 16 November 2013 and 15 February 2014.

The Project elements searched during this period were the Gen-tie Line; Medium-voltage Overhead (MVOH) Line; Evaporation Pond; Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11; and the perimeter fences and control plots associated with arrays 1, 2, 4, 6, 7, 8, and 11. This quarterly[1] report does not include the results of searcher efficiency trials, carcass removal trials, or data analyses, nor does it include detailed discussions. These features are provided in the annual reports.

---

[1] The quarters referred to are the monitoring quarters specified in the COA. The first five quarters were 16 August to 15 November 2012, 16 November 2012 to 15 February 2013, 16 February to 15 May 2013, 16 May to 15 August 2013, and 16 August to 15 November. The period covered by this report is 16 November 2013 to 15 February 2014, and the next quarter will be 16 February to 15 May 2014.

ABPP Sixth Quarterly Postconstruction Fatality Report

Figure 1: Project Site with Gen-tie Line, MVOH Line and Nine Arrays

Section 2.0 Methods

Because construction of different Project elements was completed at different times, fatality searches began at varying times in the year, depending on the Project element searched (Table 1). During initial surveys of Array 2 in 2013 only the portions of the array where the Serengeti style of photovoltaic panels were installed were surveyed because that was the only portion of Array 2 that was operational at the time. Fatality surveys were expanded to 100% of Array 2 once the entire array became operational. Because all of the Serengeti style panels are installed in the north portion of Array 2, results for the Serengeti portion are included as part of Array 2 North. With the exception of Array 1, Array 2, the Gen-tie and MVOH Line, all Project elements were surveyed at 20% coverage for each element area through 31 December 2013. Beginning in January 2014, survey efforts in Array 1 and 2 were reduced to 20% coverage and the total number of control plots were reduced from 38 to 30 based on the results of a statistical error assessment (power analysis), which confirmed that sampling at least 20% of the total area of an array, or about 30 tracker units, is sufficient to provide a precise estimate of fatality rate (HTH 2014). Additionally, surveys for control plot searches were combined on one day each week to further streamline the survey effort.

Table 1. Fatality Search Commencement Dates by Project Element

Project Element	Date Fatality Searches Began
Gen-tie Line	6 June 2012
Array 1	20 September 2012
Array 2 (Serengeti portion only)	25 September 2012
Array 1 control plot	1 November 2012
Array 1 and 2 fence	25 September 2012
Array 2 North (including Serengeti) and South	27 November 2012
Array 2 control plot	30 October 2012
Array 8 (20% sample)	7 January 2013
Array 4 (20% sample)	9 January 2013
Array 4 control plots	6 February 2013
Array 4 fence (20% sample)	16 January 2013
Array 5 and fence (20% sample)	9 January 2013
MVOH Line	30 January 2013
Array 8 control plots	4 February 2013
Array 8 fence (20% sample)	20 May 2013

Note: The Serengeti portion of Array 2 was searched separately only until 27 November 2012, so the Survey period reflects the time when the Serengeti portion was sampled separately from the rest of Array2.

Fatalities were counted when surveyors found smudge marks and feather spots directly on a Project element (such as a solar panel) or feather spots on the ground; fur accompanied by flesh, blood, or bone; or a carcass. We considered a feather spot a fatality if it had at least two or more primary flight feathers, five or more tail feathers, or ten or more feathers of any type concentrated together in an area 1 square meter (m^2) or smaller (Smallwood 2007). Feathers spots not meeting these requirements but containing flesh, blood, or bone were also considered a fatality. All carcasses and feather spots were collected during each fatality survey, except in areas that overlapped with repeat surveys in Arrays 1 and 2 (see methods for "5-day Repeat Surveys").

Preening spots often have fewer feathers and are more spread out than feather spots associated with fatalities. Roosting areas rarely contain primary or secondary feathers, but are often dotted with droppings. In the solar arrays, we regularly observed flocks of roosting mourning doves (*Zenaida macroura)* and horned larks (*Eremophila alpestris*). Mourning doves exhibit a complex molt strategy, which can occur year round and includes preformative, prealternate, and definitive prebasic molts (Otis et al. 2008). Likewise, horned lark adults and first-year birds undergo a definitive prebasic molt at the end of the breeding season (typically the end of July) (Beason 1995). Searchers used their biological knowledge to determine whether or not feathers from mourning doves, horned larks, or other species known to be in a molt period should be recorded as a fatality. When feathers were determined to be part of a molt or roost spot, no data were taken.

Fatalities of non-avian or non-bat taxa were documented when found, but are not discussed in this report. However, all specimens including non-avian and non-bat fatalities were reported pursuant to state and federal salvage permit requirements. Incidental avian fatalities observed outside regular survey periods or surveyed areas were documented and are reported separately from fatalities found during regularly scheduled searches in this report. Additionally, fatalities of sensitive species were reported to the California Natural Diversity Database.

We gave each fatality a unique incident number. Incident numbers were written as follows: YYYYMMDD—#. Each searcher recorded a unique set of numbers, so data can be traced back to individual searchers. To further verify species identifications, we took photos of each fatality, and when necessary, we consulted Scott and McFarland's Bird Feathers identification book (2010). For each fatality, we recorded location (using Universal Transverse Mercator [UTM] coordinates), time found, taxon, common name, four-letter alpha code, carcass condition, parts found, number and types of feathers, and estimated time since death. Whenever possible, we recorded information about the age and sex of the fatality, as well as scavenger type. Additionally, we gathered information on the size and spread of the feather spot and the surrounding substrate, vegetation height, and percent vegetation cover, as well as whether the fatality occurred in a searcher or non-searcher row (for fatalities found in the arrays). All carcasses and feather spots discovered by regular weekly searchers were removed to avoid attracting scavengers and the potential to confuse searchers on subsequent searches if scavengers scattered parts of the carcass.

2.1 Weekly Fatality Searches

Weekly fatality searches were performed for the Evaporation Pond, Gen-tie Line; MVOH Line; Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11; and the associated control plots and fences for each array. Each week, we selected random start locations for each Project element using a random number generator. Random selection was based on tower numbers (for the Gen-tie Line), line segment (for the MVOH Line), numbered array corners (for the solar arrays), and numbered fence corners (for the perimeter fence).

A team of two biologists searched a 30-meter (m)-wide transect centered under the complete length of the Gen-tie Line. Because of the relatively shorter height of the MVOH Line, it was assumed that carcasses would have less potential to distribute over a wide area (HTH 2011); therefore, the transect area along the entire length of the MVOH Line was only 18 m wide. Each person searched half the transect width and half the tower or pole radial areas for both the Gen-tie and MVOH Lines. On the Gen-tie Line, each person searched a 15-m-wide transect for large birds and a 6-m-wide transect for small birds and bats. On the MVOH Line, each person searched a 9-m-wide transect for small and large birds.

In the arrays, biologists searched tracker units in teams of two. In each tracker unit, biologists walked into every other row of panels and visually scanned both the row walked and each adjacent row. To avoid crossing the drive arms of the tracker units, searchers turned around upon reaching the drive arm, and continued to scan the next row as they proceeded out of the row. Thus, although searchers walked only every other row, they visually scanned adjacent rows to ensure full coverage.

To determine background rates of mortality, control plots were established on adjacent onsite Conservation Lands (plots were within 1 km of Arrays 1, 2, 4, 6, 7, 8, and 11). Each control plot had the same dimensions as a tracker unit (i.e., equivalent to 18 rows of solar panels, with 40 panels to a row). We used pin flags or wooden stakes to delineate mock panel trackers on the control plots, and searchers followed the same pattern and procedure used for searching the arrays. Control plots were not established for the 20% sample of Array 5 or 9 because the 20% search area for these arrays contained too few trackers to meet the control plot establishment guidelines set forth in the Avian and Bat Fatality Monitoring Plan for the California Valley Solar Ranch (Appendix A *in* HTH 2011; one control plot for 16 tracker units searched).

Fence segments surveyed for Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11 (100% of Array 1 and 2 fences through 31 December 2013 and then 20% from 1 January 2014 on; and 20% of Array 4, 5, 6, 7, 8, 9, and 11 fences) were each searched by one biologist. Each week, the biologist walked the inside portion of the fence while scanning a 6-m-wide belt centered on the fence. In some cases, the fences were not completely built until after weekly searches had already commenced. In these instances, fences were included only as part of the regular search routine after they were completely installed.

The Evaporation Pond was surveyed by two biologists. Each week, one biologist walked the perimeter of the pond inside the fenced area while scanning the pond and a 6-m-wide belt centered on the fence. Before entering the fenced area, the biologist also scanned the pond to assess avian activity. The second biologist walked the perimeter of the pond outside the fenced area.

In most cases, missed surveys were not repeated in the same week because they were conducted only on designated days as part of the survey protocol. For estimating the total number of fatalities, the fatality model accounted for search intervals of different lengths due to missed surveys (e.g., if a weekly search day was cancelled because of rain, the search effort would resume the following week and for that search, the interval was 14 days, not 7 days).

2.2 5-day Repeat Surveys

In addition to regular weekly searches, two types of repeat surveys were conducted. The 5-day repeat surveys were designed to serve several functions: (1) to identify a portion of the fatalities missed by regular weekly searchers, (2) to give limited estimates of the permanence of both feather spots and carcasses, (3) to provide an independent estimate of site-wide fatalities, and (4) to help estimate carcass deposition rates. Five-day repeat surveys were conducted on all Project elements subject to regular weekly searches, with the exception of the Gen-tie Line, which was not included in the 5-day repeat surveys because it was assumed that small birds and bats would be unlikely to strike high-tension power lines. Each of the remaining sites was subjected to 5-day repeat surveys once every 4 weeks, and surveys were organized so that a 5-day repeat was conducted for a different site each week.

During each 5-day repeat survey period, searchers covered the same 25% or 5% portion of a given Project element (Arrays 1, 2, 4, 5, 6, 7, 9, 11, and MVOH Line) for 5 consecutive days. Repeat searches of arrays also included searches of associated perimeter fences and control plots. However, because of the size of Array 2, conducting a 5-day survey of both Array 2 Serengeti and Array 2 North and South was not feasible. Therefore, these portions of Array 2 were treated as separate sites for the purposes of 5-day repeat surveys.

Five-day repeat surveys were originally conducted in the same areas as regular weekly searches for all arrays. However, in June 2013, this protocol was changed, and new, non-overlapping areas were established for 5-day repeat surveys in Arrays 4, 5, and 8, to keep the search interval at a constant span of 7 days for all weekly searches. In Arrays 1 and 2, however, overlapping search areas were unavoidable because weekly searches encompass 100% of the arrays. Under the revised protocol, feather spots and scavenged carcasses were still collected on the fifth day of each 5-day repeat survey, but any intact carcasses found were used in the carcass-removal trials, and camera traps were placed by the carcasses to record the activity of scavengers and monitor the persistence of the carcass past the 5-day span of the repeat survey. Then, the first day of each 5-day repeat survey was treated as a clearance search, and all fatalities found on the first day were removed from further analysis.

2.3 1-Day Repeat Surveys

One-day repeats (carcass-detectability bias-correction surveys) represent a second type of repeat search, designed to identify a portion of the fatalities missed by weekly searchers. Every other week, a 1-day repeat survey was conducted on the day following regular weekly searches. One-day repeat searches were also conducted after each 5-day repeat survey on either the last day of the 5-day survey or 1 day after completion of the 5-day survey. These repeat searches were conducted to provide further estimates of the detectability of small bird and bat carcasses. Each 1-day repeat survey covered a randomly selected 25% of all elements searched in the weekly or 5-day repeat survey. For example, the 1-day repeat survey of Array 2 included a search of 25% of the array, 25% of the fence, and 25% of the associated control plots.

2.4 Discontinuation of Repeat Surveys

The first fatality estimates for the Project site were completed in the fall of 2013. Although 5-day repeats were designed to provide a verification of the results found by weekly searches, the low number of tracker units that were searched for each 5-day repeat survey resulted in greatly inflated confidence intervals for these independent estimates compared to the estimates of the weekly searches. As a result, the value of these independent estimates was greatly reduced. Five-day repeats were also designed to create a shorter search interval that would allow carcasses with a short scavenging time to be more readily found and identified. However, after completing the 5-day repeat surveys for more than a year, it became apparent that avian fatalities, particularly long-lasting feather spots, accounted for the bulk of the survey detections. Because repeat surveys are labor intensive, there is generally a tradeoff between the total area that can be covered, and the frequency of the searches. All repeat surveys (both 5-day and 1-day repeat surveys) ceased 1 January 2014 onward because of this tradeoff in combination with the reasons outlined above.

Section 3.0 Results

3.1 Weekly Fatality Searches

All Project elements were surveyed weekly, with the following exceptions:

- Surveys were not conducted for Arrays 4, 5, 9, and 11, the Gen-tie Line and the MVOH line on 20 November 2013 and for Arrays 1 and 7 on 21 November 2013, in observance of the Thanksgiving holiday.
- Surveys were not conducted for Array 2 on 24 December 2013, for 4, 5, 9, and 11, the Gen-tie Line and the MVOH line on 25 December 2013, and for Arrays 1 and 7 on 26 December 2013, and for Array 8 on 30 December 2013 in observance of the Christmas holidays.
- Surveys were not conducted for Arrays 4, 5, 9, 11, the Gen-tie Line and the MVOH line on 1 January 2014 in observance of the New Year's Day holiday.
- Surveys were not conducted in Arrays 1, 7, and 9 on 30 January 2014 and 6 February 2014 because of inclement weather conditions.
- Surveys were not conducted in Array 2 on 6 February 2014 because of inclement weather conditions.

One hundred and fifty-two avian fatalities were counted between 16 November 2013 and 15 February 2014 in the surveyed operational portions of the Project site (Appendix A, Table A-1). One hundred and forty-five of the avian fatalities were counted from feather spots, and seven were counted from whole or partial carcasses. All fatalities were mapped (Figures 2 through 6), and a summary of the fatality searches was compiled (Table 2). Twelve avian species, plus four unidentified birds, including one passerine, one raptor and two large birds, were represented in the detected fatalities (Appendix A, Table A-2). As documented in previous quarterly fatality reports, mourning doves were the most numerous fatalities observed (70) and house finches (*Carpodacus mexicanus*) were the second highest fatality (37). Fewer western meadowlark (*Sturnella neglecta*) fatalities (17) were observed than in previous quarters. No bat fatalities were observed during this survey period.

The whole of Array 2 presented the most fatalities (27) and Array 4 presented the second highest number of fatalities (22). Most of the avian fatalities found in all survey areas were indicated by feather spots. However, a small number of whole and partial carcasses were also discovered. In solar arrays, feather spots were primarily observed on the ground near panels, but portions of three fatalities were found near and on panels. Each of the panel fatalities presented some combination of feathers and/or body fluids smudged across the panels. Two out of the four whole carcasses that were found showed signs of death by either predation or illness. One carcass was clearly predated, based on decapitation of the carcass, which is typical of many avian predators. The other carcass showed signs of illness based on low body fat (palpable keel) and the presence of fecal matter in matted down feathers near the cloaca. For two other whole carcasses, no injuries were apparent and the cause of death was therefore difficult to determine.

Table 2. Summary of Avian Fatality Searches Conducted between 16 November 2013 and 15 February 2014, and Fatality Totals

Project Element	Total Fatalities	Fatalities Counted from Feather Spots	Fatalities Indicated by Evidence Other than Feather Spots, and Notes
Array 1	1	1	n/a
Array 1 controls	1	1	n/a
Array 2 North	8	7	One whole carcass was decapitated, suggesting either avian or mammalian predation.
Array 2 South	19	19	n/a
Array 1–2 fence	3	3	n/a
Array 2 controls	4	5	n/a
Array 4	22	21	One partial carcass, consisting of feathers, internal organs and bill.
Array 4 fence	2	2	n/a
Array 4 controls	1	1	na
Array 5	5	5	n/a
Array 5 fence	1	1	n/a
Array 6	15	14	One whole carcass found below cable tray. No obvious sign of injury.
Array 6 fence and controls	0	0	n/a
Array 7	15	13	One whole carcass with no obvious sign of injury and one partial carcass consisting of feathers and internal organs.
Array 7 fence or controls	0	0	n/a
Array 8 Circuit 2	15	15	n/a
Array 8 fence	1	0	One partial carcass consisting of feathers, skin, one leg and one thigh.
Array 8 controls	0	0	n/a
Array 9	2	2	n/a
Array 9 fence	0	0	n/a
Array 11 and fence	0	0	n/a
Array 11 controls	1	1	n/a

MVOH Line	13	14	n/a
Gen-tie Line	10	10	n/a
Evaporation Pond	4	3	One whole carcass with dried blood on bill, dried feces around cloaca, and keel noticeably palpable.
Reduced search effort to 20% beginning 1 January 2014			
Array 1	1	1	n/a
Array 2	7	7	n/a
Array 1-2 fence	1	1	n/a
Total Fatalities	**152**		

Notes:

[1] This table only includes fatalities detected during fatality searches. Incidental fatalities are reported in the text of Section 3.1 and Table A-2 in Appendix A.

One avian fatality was counted in Array 1 prior to reducing the search effort to 20% and one fatality was counted in a control plot associated with Array 1 (Table 2; Figure 2) after reducing the control plot survey effort. One avian fatality was counted in Array 1 (Table 2, Figure 3) after reducing the search effort to 20%. All fatalities were counted from feather spots.

Thirty-four fatalities were counted in the Array 2 elements, including Array 2 North and South, perimeter fence and associated controls, prior to reducing the search effort to 20%. Eight avian fatalities were counted in Array 2 North (Table 2; Figure 2). One of these fatalities was counted from a decapitated carcass. This type of injury is consistent with a predation event. Nineteen avian fatalities were counted in Array 2 South (Table 2; Figure 2), all based upon feather spots. One burrowing owl (*Athene cunicularia*), a California Species of Special Concern, accounted for one of these fatalities. Additionally, feathers and smudged body fluid from a western meadowlark fatality were observed on top of one panel and may indicate a panel strike. Seven fatalities, all feather spots, were counted along the perimeter fence surrounding Arrays 1 and 2. Four avian fatalities were counted from feather spots in control plots associated with Array 2. After reducing the search effort to 20%,seven avian fatalities were counted in Array 2 and one fatality was counted along the perimeter fence surrounding Arrays 1 and 2 (Table 2; Figure 3). All fatalities found after reducing the search effort were counted from feather spots.

Twenty-five avian fatalities were counted in Array 4 elements, including Array 4, the perimeter fence and control plots (Table 2; Figure 4). Twenty-two fatalities were counted in Array 4. One fatality was counted in a control plot associated with Array 4. Two fatalities were found along the perimeter fence and were counted from feather spots. All but one of these fatalities were counted from feather spots. One partial carcass, consisting of feathers, internal organs, and bill was also found in the array.

Six avian fatalities were counted in Array 5 elements, including Array 5 and the perimeter fence (Table 2; Figure 4). One fatality was observed in Array 5 and one was observed along the perimeter fence. All were counted from feather spots.

Fifteen fatalities were observed in Array 6 (Table 2; Figure 4). All but one fatality were counted from feather spots. The whole carcass of a house finch was found below cable trays within the array and did not show signs of injury or illness. One loggerhead shrike (*Lanius ludovicianus*), a California Species of Special Concern, accounted for one of these fatalities. Feathers and smudge marks from body fluid were observed on a panel suggesting a panel strike. No fatalities were observed along the Array 6 perimeter fence or control plots.

Fifteen fatalities were counted in Array 7 (Table 2; Figure 5). All but two of these fatalities were counted from feather spots. One whole carcass of a house finch showed no signs of injury or illness. One partial carcass of a house finch consisted of feathers and internal organs. No fatalities were observed along the fence or in control plots associated with Array 7.

Fifteen fatalities, all counted from feather spots, were counted in Array 8 Circuit 2 (Table 2; Figure 6). Feathers from one of these fatalities were smudged across one panel suggesting a panel strike. One fatality, counted from a partial carcass, was found along the perimeter fence surrounding the array. Several portions of this fatality were impaled on a tumbleweed branch, suggesting that this was a loggerhead shrike kill. No fatalities were observed in control plots associated with this array.

Two fatalities were found in Array 9 (Table 2; Figure 6). Both fatalities were counted from feather spots. No fatalities were observed along the perimeter fence associated with this array.

One fatality was found in a control plot associated with Array 11 (Table 2; Figure 6). No fatalities were found in Array 11 or the perimeter fence associated with this array.

Thirteen fatalities were counted along the MVOH Line (Table 2; Figure 7). All of these fatalities were counted from feather spots and all were found directly, or nearly directly, under the MVOH Line.

Ten fatalities were counted along the Gen-tie Line (Table 2; Figure 8). All of these fatalities were counted from feather spots and all were found directly, or nearly directly, under the Gen-tie Line.

Four fatalities were found in or around the Evaporation Pond (Table 2; Figure 2). Two fatalities were counted from feather spots and both were found outside of the perimeter fence surrounding the pond. One additional feather spot was found outside the fenced area. One whole house finch carcass was also found outside the fence surrounding the pond. This bird may have been ill at the time of death. A palpable keel indicated low body weight and matted feather and feces around the cloaca may also indicate illness.

Figure 8: Locations and Species of Postconstruction Fatalities Observed along Gen-tie Line between 16 November 2013 and 15 February 2014

Fourteen additional avian fatalities were found incidentally along the MVOH line, and in Arrays 2, 4, 6, 7, 8, 9 and their associated elements (Appendix A, Table A-3). All but one of these fatalities were counted from feather spots. One whole carcass of a mourning dove was found along the perimeter fence associated with Array 7. This carcass did not show signs of injury or illness. Additionally, one burrowing owl feather spot was found in Array 9.

3.2 5-day Repeat Surveys

During the 5-day repeat surveys conducted during this reporting period, 11 avian fatalities were observed (Table 3). Of these 11 fatalities, one was found in Array 1, six were found in Array 4, one was found on the Array 4 fence, one was found in Array 8, one was found on the Array 8 fence, and one was found along the MVOH line. No fatalities were found in any of the other arrays or project elements. No bat fatalities were observed during this survey period.

3.2.1 Array 1

Array 1 and its associated fence were surveyed two times during this reporting period. No fatalities were found during the week of 16 December 2013, but one was found during the week of 17 November: a feather spot of a house finch. This feather spot persisted until the fifth day of the survey, when it was collected.

3.2.2 Array 4

Array 4 was searched one time during this reporting period, during the week of 9 December. On 9 December, searchers were shut-out of all arrays due to safety concerns, shifting the first day of the repeat survey to Tuesday, 10 December. The fifth day of the repeat survey was not rescheduled due to scheduling conflicts. Three mourning dove feather spots and one feather spot of a western meadowlark were found on 10 December. Because this was the first day of the search period, they were collected immediately. On 12 December, a mourning dove feather spot was found. This feather spot persisted until the next and final day of the survey period, when it was collected. On 13 December, we found another mourning dove feather spot in this array. Because it was found on the last day of the search period, it was collected immediately.

3.2.3 Array 4 Fence

The Array 4 fence was searched one time during this period, during the week of 9 December. On 9 December, workers were shut out of the array due to safety concerns, so neither the fence nor the array was searched until 10 December. On 10 December, we found a mourning dove feather spot along the fence. Because it was found on the first day of the search, it was considered a clearance carcass, and it was collected immediately.

3.2.4 Array 8

Array 8 was surveyed one time during this reporting period, and one fatality was found. On 10 December, the feather spot of a mourning dove was found. It persisted until the end of the week, when it was collected.

3.2.1 Array 8 Fence

The fence of Array 8 was surveyed one time during this reporting period, and one fatality was found. On 10 December, we found a mourning dove feather spot. It persisted until the end of the week, when it was collected.

3.2.2 MVOH Line

The MVOH Line was surveyed one time during this reporting period, and we found one fatality. On 3 December, the feather spot of a burrowing owl was found along the MVOH Line. The feather spot persisted until the last day of the 5-day survey, when it was collected.

3.3 1-Day Repeat Surveys

3.3.1 Weekly Search Areas

Seven avian fatalities were observed in Project areas that were surveyed during 1-day repeat surveys that occurred in this reporting period (Table 4). No bat fatalities were observed during this period. All fatalities were found in the 1-day repeat survey areas of Array 2 North and South, Array 2 Serengeti, Array 6, Array 7, and the Gen-tie Line; no fatalities were found in the 1-day repeat survey areas of any other Project element.

3.3.1.1 Array 2 North and South

The feather spot of a savannah sparrow (*Passerculus sandwichensis*) was found in Array 2 South on 4 December. On 18 December, two fatalities were found in Array 2 North. A western meadowlark was found at mid-day in Array 2 North, when the panels were flat, and some feathers and blood were located on the panel. Because loose clumps of feathers were located on the panel, it is likely that the carcass was found and scavenged within approximately three hours prior to its discovery. The location of the scavenged remains on the panels rules out the possibility that it was scavenged by a mammal. Therefore, it was likely scavenged by a bird such as a common raven. We also found a mourning dove carcass in Array 2 North on 18 December. It had visible blunt force trauma to its chest and right shoulder, and visible bruising on its right foot. The wounds were not fresh, so it is likely that the trauma occurred several days prior, and had begun to heal when the bird died. We determined that all three of these fatalities were new, due to the freshness of the carcasses and high visibility of the locations where they were found.

3.3.1.2 Array 2 Serengeti

On 11 December, a common raven feather spot was found in Array 2 Serengeti. This fatality was likely missed by weekly searchers.

3.3.1.3 Array 6

On 31 December, searchers found the large feather spot comprising a mourning dove in Array 6. This fatality was likely missed by weekly searchers.

3.3.1.4 Array 7

On 20 December, the feather spot of a Eurasian collared dove was found in Array 7. This feather spot was thought to be a fresh feather spot that was not missed by weekly searchers.

3.3.1.5 Gen-Tie Line

On 5 December, a savannah sparrow feather spot was found along the Gen-tie Line. Some of the feathers were matted into the ground, so it is likely that this feather spot was missed by weekly searchers.

3.3.2 5-day Repeat Survey Areas

During the 1-day repeat surveys of 5-day search areas, conducted between 16 November and 31 December, no fatalities were observed in the Project areas that were surveyed.

Table 3. Results of 5-Day Repeat Surveys Conducted between 16 November 2013 and 15 February 2014

Location	Survey Period	Date Fatality Detected	Number of Days that Fatality Persisted	Species	UTM Zone	Easting	Northing	Observation Details
Array 1	17-21 Nov 2013	19 Nov 2013	3	HOFI	11S	234008	3915554	Feather spot of an adult male house finch consisting of 5+ wing feathers, 300+ body feathers, and 3 tail feathers.
Array 4	10-13 Dec 2013	10 Dec 2013	NA	MODO	11S	235544	3913728	Feather spot consisting of 3 tail feathers, 2 flight feathers, and 15 body feathers.
Array 4	10-13 Dec 2013	10 Dec 2013	NA	MODO	11S	235713	3913580	Feather spot consisting of 50 body feathers and 4 flight feathers.
Array 4	10-13 Dec 2013	10 Dec 2013	NA	MODO	11S	235536	3913664	Feather spot consisting of 10 primary feathers and 40 body feathers.

Array 8	9-13 Dec 2013	10 Dec 2013	4	MODO	11S	234411	3912264	Feather spot consisting of 10-15 flight feathers and 30 body feathers. Likely missed during previous search.

UTM = Universal Transverse Mercator.

Species Codes
HOFI – house finch
MODO – Mourning dove
WEME – Western meadowlark

Table 4. Results of 1-Day Repeat Surveys Conducted in Weekly Search Areas between 16 November 2013 and 15 February 2014

Site	Date of Weekly Search	Date Fatality Detected	Species	UTM Zone	Easting	Northing	Observation Details
Array 2 North	17 Dec 2013	18 Dec 2013	MODO	11S	233908	3914955	Fresh carcass with blunt force trauma to abdomen and right shoulder and bruising on right foot. Found in a grass clump directly below tilted panel. Wounds look recent but not fresh. It is likely that they occurred several days earlier and had begun to heal when the bird died.
Array 2 North	17 Dec 2013	18 Dec 2013	WEME	11S	233803	3914993	Feather spot consisting of 7 flight feathers and 200+ body feathers. Feathers spread across row and panel. Presence of loose clumps of feathers on flat solar panels suggests that the bird was very recently scavenged by a raven.
Array 2 South	3 Dec 2013	4 Dec 2013	SAVS	11S	234160	3914847	Feather spot consisting of 100+ body feathers, and 12 primaries and secondaries. Likely a new feather spot.
Array 2 Serengeti	10 Dec 2013	11 Dec 2013	CORA	11S	234489	3915098	Feather spot consisting of ~20 body feathers. Likely missed by weekly searchers.
Array 6	30 Dec 2013	31 Dec 2013	MODO	11S	235570	3913160	Feather spot consisting of 20 body feathers and 5 contour feathers. Likely missed by weekly searchers.
Array 7	19 Dec 2013	20 Dec 2013	ECDO	11S	237717	3912921	Feather spot consisting of two tertiary and 18 body feathers, in two clumps along the middle of the cable tray.
Gen-tie Line	4 Dec 2013	5 Dec 2013	SAVS	11S	234448	3914325	Feather spot consisting of 16 flight and 50+ body feathers. Feathers are matted into vegetation. Likely missed by weekly searchers.

UTM = Universal Transverse Mercator.

Species Codes
CORA – Common raven
ECDO – Eurasian collard dove
MODO – Mourning dove
SAVS – Savannah sparrow
WEME – Western meadowlark

Section 4.0 Discussion

4.1 Weekly Fatality Searches

Following the trend observed in previous quarterly fatality reports, the majority (95%, or 145 of 152) of post construction fatalities detected in the sixth quarter were counted from feather spots, making it difficult to determine the definitive causes of death. Feather spots may indicate collision with a solar panel or a power line, but in the absence of evidence of bodily injuries, it is impossible to determine the direct cause of death. For example, feather spots can indicate nonlethal panel strikes, with fatalities occurring when predators take advantage of a stunned bird. In this situation, although the cause of death is only indirectly related to the presence of the panels, it would still be classified as being caused by a collision. The injured, but partially healed mourning dove found in Array 2 during repeat surveys supports the assertion that collisions may not result in immediate death, but are ultimately the cause of death. Feather spots may also indicate that a lethal panel collision or power line collision occurred, and that the body was later scavenged. Alternatively, feather spots may simply indicate direct mammalian or avian predation. Because no direct observations of predation or collisions were made during this period, causes of death could not be determined.

Mourning doves commonly roost under the panels and this species comprises the greatest numbers of fatalities. When they were flushed, we observed these birds quickly navigating through the panels; in this high-clutter environment, some birds may fly into structural elements of the array and not necessarily the upper side of the panel. Species that fly in flocks seem to be at a greater risk of collision; it has been posited that birds flying in the rear of flocks are more likely to be unaware of upcoming obstacles (Janss 2000). Additionally, the relatively high densities of these species' flocks may provide greater opportunities for avian and mammalian predators to prey on these birds. House finches represented the second most frequently detected species of fatality. A similar pattern of mortality was observed for mourning doves and house finches in the 2nd quarterly report covering 16 November 2012 to 15 February 2013. In contrast, horned lark fatalities declined from previous quarters and they were observed much less frequently in arrays than mourning doves and house finches. The reduction in the number of horned larks may be due to vegetative growth under the arrays following construction.

Because surveys of the control plots detected background avian mortality, a corresponding percentage of the total fatalities found in each of the arrays was likely attributable to natural causes unrelated to the solar panels and other Project infrastructure. In the next annual fatality report, the fatality estimate for the Project will be adjusted accordingly to reflect this background mortality.

Although assessing cause of death from feather spots is difficult, all feather spots found along the Gen-tie and MVOH Lines were located directly, or nearly directly, under these lines. The location of these fatalities suggests that these fatalities were caused by power line collisions and that the remains found were indicative of scavenging, rather than predation. We believe that predation by resident predators also contributed to some of these fatalities.

Consistent with all previous quarters, total fatalities were higher for the entirety of Array 2 compared to Array 1 when searched at 100% coverage. After reducing the search effort in both arrays, the outcome was similar for these arrays, with more fatalities in the 20% search area of Array 2 compared with the 20% search area of Array 1. As discussed in previous quarterly reports, the Gen-tie Line, which is located directly east of and closest to Array 2 may provide a protected area where scavengers may consume carcasses found near this transmission line. Of all sites surveyed at 20% for the entire quarter, Array 4 had the highest number of fatalities and Arrays 6, 7, and 8 had the second highest number of fatalities. In comparison, Arrays 9 and 11 had very few fatalities. Vegetation in Arrays 9 and 11 is very sparse and composed predominantly of bare ground. It’s likely that fewer fatalities were found in Arrays 9 and 11 because fewer birds were attracted to these areas due to the lack of suitable roosting and foraging habitat. No fatalities were found in Array 5, possibly because of the small size of this array and the low number of trackers (four) searched.

While only four fatalities were observed at the evaporation pond, all were discovered on the same day. One intact carcass showed signs of illness (emaciation) and trauma (beak injury), so the direct cause of death remains inconclusive. That several fatalities were found during the same survey is not unusual because large flocks of birds, especially house finches, were periodically observed outside the pond for several weeks during the early part of the 6th quarter. These flocks likely attracted predators which could be associated with these fatalities.

4.2 Repeat Surveys

A general assumption of fatality searches is that searchers are not 100% efficient at finding carcasses, because of both environmental and individual constraints (e.g., vegetation height, visual obstacles such as support poles for the arrays, and observer fatigue). The results of the 1-day and the 5-day repeat surveys support this assumption, because several of the fatalities were missed by weekly searchers. Although the number of fatalities found by weekly searchers (but missed by repeat searchers) was not examined, there are recorded cases of weekly searchers finding fatalities that repeat searchers did not find; therefore, searcher misses go in both directions. Also, the low rates of consistency between the findings of regular weekly searchers and those of repeat searchers suggest that search outcomes may be affected by both random differences and differences that vary by individual searcher. For example, a taller searcher will have a reduced field of vision into adjacent rows compared to a shorter searcher. This variation is unlikely to be fully compensated for, even with conscious efforts to look under the panels. Likewise, there are tradeoffs based on where searchers focus their field of vision: if a searcher focuses on tufts of tall grass on the sides of array rows, he or she may overlook fatalities directly underfoot, and vice versa.

All 5-day and 1-day repeat searches were discontinued during this quarter. These repeat surveys were determined to provide limited value in terms of extra information.

Section 1.0 Introduction

Through adoption of Resolution #2011-119, the Board of Supervisors of San Luis Obispo County (the County) approved the California Valley Solar Ranch Project (CVSR Project) Conditional Use Permit (DRC 2008-00097) on 19 April 2011. The Conditional Use Permit is subject to the Conditions of Approval (COAs) set forth in Exhibit 6 attached to the Resolution.

The Conditional Use Permit allows High Plains Ranch II, LLC (and any successor in interest for the life of the CVSR Project), to construct and operate a 250-megawatt photovoltaic solar power plant within an approximately 4685-acre site (Project site), located mostly south of State Route (SR) 58, about 6.4 kilometers (km) east of Soda Lake Road, immediately north of the California Valley subdivision, in the Shandon-Carrizo planning area of San Luis Obispo County (Figure 1).

COA #58 of the Conditional Use Permit requires an Avian and Bat Protection Plan (ABPP) and a quarterly report detailing any Project-related bird or bat deaths or injuries detected. To satisfy COA #58, H. T. Harvey & Associates (HTH), on behalf of High Plains Ranch II, LLC, has prepared this postconstruction fatality report, which documents the number of avian and bat fatalities counted during Project postconstruction monitoring between 16 May and 15 August 2014.

The Project elements searched during this period were the Generation-tie (Gen-tie) Line; Medium-voltage Overhead (MVOH) Line; Evaporation Pond; Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11; the perimeter fences for each array; and control plots associated with Arrays 1, 2, 4, 6, 7, 8, and 11. This quarterly[1] report does not include the results of searcher-efficiency trials, carcass-removal trials, or data analyses, nor does it include detailed discussions. These features are provided in the annual reports. Quarterly and annual reports detailing any Project-related bird or bat deaths or injuries detected are required for 3 years following the beginning of the CVSR Project operation. The fatality monitoring program as defined in the ABPP continues for one year after completion of construction.

---

[1] The quarters referred to are the monitoring quarters specified in the COA. The first seven quarters were 16 August to 15 November 2012, 16 November 2012 to 15 February 2013, 16 February to 15 May 2013, 16 May to 15 August 2013, 16 August to 15 November 2013, 16 November 2013 to 15 February 2014, and 16 February to 15 May 2014. This quarterly report covers 16 May to 15 August 2014, and the next quarter will be 16 August to 15 November 2014.

ABPP Eighth Quarterly Postconstruction Fatality Report
Figure 1: Project Site with Gen-tie Line, MVOH Line, Evaporation Pond, Nine Arrays and Control Plots

Section 2.0 Methods

2.1 Overview of Fatality Searches to Date

Because construction of different Project elements was completed at different times, fatality searches began at varying times in the year, depending on the Project element searched (Table 1). During initial surveys of Array 2 in 2013, only the Serengeti style portions of the array were surveyed because only these areas of Array 2 were operational at the time. Fatality surveys were expanded to 100% of Array 2 once the entire array became operational. With the exception of Array 1, Array 2, and the Gen-tie and MVOH Lines, all Project elements were each surveyed at 20% coverage through 31 December 2013. Beginning in January 2014, survey efforts in Arrays 1 and 2 were reduced to 20% coverage, and the total number of control plots was reduced from 38 to 30. These changes within Arrays 1 and 2 were made based on the results of a statistical error assessment which confirmed that sampling at least 20% of the total area of an array, or about 30 tracker units per array, is sufficient to provide an accurate estimate of fatality rate (HTH 2014). Additionally, searches of control plots were combined to occur on 1 day each week to further increase the efficiency of the survey effort.

Table 1. Fatality Search Commencement Dates by Project Element

Project Element	Date Fatality Searches Began
Gen-tie Line	6 June 2012
Array 1[1]	20 September 2012
Array 2 (Serengeti portion only)[2]	25 September 2012
Array 1 and 2 fence[1]	25 September 2012
Array 2 control plots	30 October 2012
Array 1 control plot	1 November 2012
Array 2 North (including Serengeti) and South[1, 2]	27 November 2012
Array 8 (20% sample)	7 January 2013
Array 4 (20% sample)	9 January 2013
Array 5 and fence (20% sample)	9 January 2013
Array 4 fence (20% sample)	16 January 2013
MVOH Line	30 January 2013
Array 8 control plots	4 February 2013
Array 4 control plots	6 February 2013
Array 8 fence (20% sample)	20 May 2013
Array 6 and fence (20% sample) and control plots	30 September 2013
Array 7 and fence (20% sample) and control plots	10 October 2013
Array 9 and fence (20% sample)	6 November 2013
Array 11 and fence (20% sample), and control plots	6 November 2013
Evaporation Pond	11 November 2013

Note:

[1] Sampling reduced to 20% of total array area (starting 2 January and 7 January 2014 for Array 2 and 1, respectively).

[2] The Serengeti portion of Array 2 was searched separately only until 27 November 2012 (3 days).

2.2 Data Recordation

Fatalities were counted if surveyors found smudge marks and feather spots directly on a Project element (such as a solar panel) or feather spots on the ground; feathers or bat fur accompanied by flesh, blood, or bone; or a carcass. Searchers considered a feather spot a fatality if it had at least two or more primary flight feathers, five or more tail feathers, or ten or more feathers of any type concentrated together in an area 1 square meter (m^2) or smaller (Smallwood 2007). Feather spots not meeting these requirements but containing flesh, blood, or bone were also considered a fatality.

Preening spots typically have fewer feathers and are more spread out than feather spots associated with fatalities. Roosting areas rarely contain primary or secondary feathers but are often dotted with droppings. In the solar arrays, searchers regularly observed flocks of roosting mourning doves (*Zenaida macroura)* and horned larks (*Eremophila alpestris*). Mourning doves exhibit a complex molt strategy which can occur year round and includes preformative, prealternate, and definitive prebasic molts (Otis et al. 2008). Likewise, horned lark adults and first-year birds undergo a definitive prebasic molt at the end of the breeding season (typically the end of July) (Beason 1995). Searchers used their biological knowledge to determine whether or not feathers from mourning doves, horned larks, or other species known to be in a molt period should be recorded as a fatality. No data were taken on molt or roost-spot feathers.

Fatalities of nonavian or nonbat taxa were documented when found, but are not presented or discussed in this report. However, all specimens, including nonavian and nonbat fatalities, were reported pursuant to State and federal salvage permit requirements. Additionally, a Migratory Bird Special Purpose Utility Salvage Permit (SPUT) for the Project was issued by the U.S. Fish and Wildlife Service (USFWS) on 10 March 2014 (permit number MB02733B-0). Pursuant to this permit, data on all avian fatalities collected during routine surveys or incidentally were submitted on a quarterly basis using the electronic injury or mortality report spreadsheet provided by USFWS. Although no incidental fatalities (i.e., outside regular survey periods or surveyed areas) were detected during this reporting period, such detections are distinguished from fatalities found during regularly scheduled searches.

The suspected cause of death was assessed for all fatalities and assigned to one of the following classes: collision, electrocution, predation, or unknown. It was then further assigned a "Level of Certainty for Suspected Cause" category, as defined in the SPUT (Observed = 100%; Valid = >90%; Probable = >50%; Possible = <50%; or Unknown/Not Applicable). To make the assessment, searchers carefully examined all carcasses for signs of injury or illness. No carcasses found during the reporting period showed signs of illness. Although whole carcasses with noticeable injuries (e.g., a broken wing, beak, or other blunt-force trauma) were not found during this reporting period, such specimens, when found in arrays or along powerlines, are assumed to represent deaths caused by collision, with a high level of certainty (Valid) for suspected cause of death. Whole carcasses exhibiting no signs of injury, as well as feather spots found in the arrays and along perimeter fences, were assigned an unknown cause of death because there was no compelling evidence to indicate how these fatalities occurred. However, when visibly uninjured whole carcasses and feather spots were found directly or nearly directly under the Gen-tie or MVOH Lines, these fatalities were considered powerline collisions, with Probable (>50%) certainty. Most of the fatalities found directly under these powerlines were of migratory species rarely documented in the arrays; this suggests that the birds were flying at a height where a powerline interaction could occur, potentially resulting in fatality. Lastly, although no electrocutions were found during the reporting period, these cases are typically assigned Valid (>90%) certainty if the carcass shows signs of burning or singeing on the legs, wings, or body.

Each fatality was assigned a unique incident number. Incident numbers were written as follows: YYYYMMDD—#. Each searcher recorded a unique set of numbers, so that data can be traced back to individual searchers. To further verify species identities, searchers photographed each fatality, and, when necessary, consulted Scott and McFarland's *Bird Feathers: A Guide to North American Species* (2010). For each fatality, the following data were recorded: location (using Universal Transverse Mercator [UTM] coordinates), time found, taxon, common name, four-letter alpha code, carcass condition, parts found, number and types of feathers, and estimated time since death. Whenever possible, information about the age and sex of the fatality, as well as scavenger type, was noted. Additionally, searchers gathered information on the size and spread of the feather spot and the surrounding substrate, vegetation height, and percent vegetation cover, as well as whether the fatality occurred in a searcher or nonsearcher row (for fatalities found in the arrays). All carcasses and feather spots discovered by regular weekly searchers were removed to avoid attracting scavengers and to prevent confusion in subsequent searches (which might occur if scavengers scattered parts of carcasses).

2.3 Fatality Search Methods

Weekly fatality searches were performed for the Evaporation Pond, Gen-tie Line; MVOH Line; Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11; fences for each array; and the associated control plots for arrays 1, 2, 4, 6, 7, 8, and 11. Each week, random start locations were selected for each Project element using a random number generator. Random selection was based on tower numbers (for the Gen-tie Line), line segment (for the MVOH Line), numbered array corners (for the solar arrays), and numbered fence corners (for the array perimeter fences).

A team of two biologists searched a 30-meter (m)-wide transect centered under the complete length of the Gen-tie Line. Because of the relatively shorter height of the MVOH Line, it was assumed that carcasses would have less potential to be distributed over a wide area (HTH 2011); therefore, the transect area along the entire length of the MVOH Line was only 18 m wide. Each person searched half the transect width and half the tower or pole radial areas for both the Gen-tie and MVOH Lines. Under the Gen-tie Line, each person searched a 15-m-wide transect for large birds and a 6-m-wide transect for small birds and bats. Under the MVOH Line, each person searched a 9-m-wide transect for small and large birds.

In the arrays, biologists searched tracker units in teams of two. In each tracker unit, searchers walked into every other row of panels and visually scanned both the row walked and each adjacent row. To avoid crossing the drive arms of the tracker units, searchers turned around upon reaching the drive arm, and continued to scan the next row as they proceeded out of the row. Thus, although searchers walked only every other row, they visually scanned adjacent rows to ensure full coverage.

To determine background rates of mortality, control plots were established on adjacent on-site Conservation Lands (plots were within 1 km of Arrays 1, 2, 4, 6, 7, 8, and 11). Each control plot had the same dimensions as a tracker unit (i.e., equivalent to 18 rows of solar panels, with 40 panels to a row). Wooden stakes were used to delineate mock panel trackers on the control plots, and searchers followed the same pattern and procedure used for searching the arrays. Control plots were not established for the 20% sample of Arrays 5 or 9 because the 20% search area for these arrays contained too few trackers to meet the control plot establishment guidelines set forth in the *Avian and Bat Fatality Monitoring Plan for the California Valley Solar Ranch* (Appendix A in HTH 2011; the guideline is one control plot [defined in the plan as having the same spatial scale as 2 aggregated tracker blocks, or 12 tracker units] for every 16 tracker blocks [96 tracker units] searched).

For each of Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11, four evenly spaced segments totaling 20% of the array's perimeter fence were searched by one biologist. Each week, the biologist walked the inside portion of the fence while scanning a 6-m-wide belt centered on the fence.

The Evaporation Pond was surveyed by two biologists. Each week, one searcher walked the perimeter of the pond inside the fenced area while scanning the pond and a 6-m-wide belt centered on the fence. Before entering the fenced area, the searcher also scanned the pond to assess avian activity. The second searcher walked the perimeter of the pond outside the fenced area.

In most cases, missed surveys were not repeated in the same week because they were conducted only on designated days as part of the survey protocol. For estimating the total number of fatalities, the fatality model accounted for search intervals of different lengths due to missed surveys (e.g., if a weekly search day was cancelled because of rain, the search effort would resume the following week and, for that search, the interval was 14 days, not 7 days).

Section 3.0 Results

All Project elements were surveyed weekly, with the following exceptions:

- In observance of the Memorial Day holiday on 26 May 2014, surveys were not conducted for Arrays 6 or 8, or for their associated perimeter fences.
- Surveys were not conducted for the Evaporation Pond on 14 July 2014.
- In observance of the Labor Day holiday on 1 September 2014, surveys were not conducted for Arrays 6 or 8, or their associated perimeter fences.

Twenty-four avian fatalities were counted between 16 May 2014 and 15 August 2014 in the surveyed operational portions of the Project site (Appendix A, Table A-1). Twenty-two (92%) of the avian fatalities were counted from feather spots, and two (8%) were counted from whole carcasses. All fatalities were mapped (Figures 2 through 6), and a summary of the fatality searches was compiled (Table 2). Twelve avian species were represented in the detected fatalities (Appendix A, Table A-2). House finches (*Carpodacus mexicanus*) and horned larks were the most frequent fatalities observed, with four fatalities each (33%). No bat or special-status avian fatalities were observed during this reporting period.

Half the fatalities were recorded along the transmission lines, and half were recorded in the arrays. The Gen-tie Line presented the most fatalities (ten, or 42% of fatalities). No fatalities were recorded in Arrays 5, 7, 8, or 9; the Evaporation Pond; control plots; or associated array perimeter fences, and overall fatality counts were low in the remaining survey areas. More than half of the avian fatalities found were indicated by feather spots. Causes of death were unknown in the arrays, and probably due to powerline collisions along the transmission lines. Of the two carcasses found, one, in an array, did not show signs of illness or injury; the second, along the MVOH Line, had likely been predated.

No incidental fatalities were detected during this reporting period.

Table 2. Results of Avian Fatality Searches Conducted between 16 May and 15 August 2014, and Fatality Totals

				Suspected Cause of Death			
Project Element	**Total Fatalities**	**Fatalities Counted from Feather Spots**	**Fatalities Counted from Whole Carcasses**	**Collision**	**Electrocution**	**Predated**	**Unknown**
Array 1	1	1	0	0	0	0	1
Array 2	2	2	0	0	0	0	2
Array 4	3	2	1	0	0	0	3
Array 6	3	3	0	0	0	0	3
Array 11	3	3	0	0	0	0	3
MVOH Line	2	1	1	1	0	1	0
Gen-tie Line	10	10	0	10	0	0	0
Total Fatalities	**24**	**22**	**2**	**11**	**0**	**1**	**12**

One fatality was counted in Array 1 (Table 2; Figure 2). This fatality was counted from a feather spot. The cause of death for this fatality is unknown.

Two fatalities were counted in Array 2 (Table 2; Figure 2). Both fatalities were counted from feather spots. The causes of death for these fatalities are unknown. No fatalities were observed along the perimeter fence surrounding Arrays 1 and 2.

Three fatalities were counted in Array 4 (Table 2; Figure 3). Two fatalities were counted from feather spots, and the cause of death is unknown. One house finch fatality was counted from a whole carcass. This carcass was completely desiccated and decomposed. It did not show any obvious signs of a panel collision. The cause of death for this whole carcass is unknown. No fatalities were observed along the Array 4 perimeter fence.

No fatalities were observed in Array 5 or along the Array 5 perimeter fence.

Three fatalities were counted in Array 6 (Table 2; Figure 3). All fatalities were counted from feather spots, and the causes of death are unknown. No fatalities were observed along the perimeter fence surrounding Array 6.

No fatalities were observed in Arrays 7, 8, or 9, or along their associated perimeter fences.

Three fatalities were counted in Array 11 (Table 2; Figure 4). All fatalities were counted from feather spots, and the causes of death are considered to be unknown. No fatalities were observed along the perimeter fence of Array 11.

Two fatalities were counted along the MVOH Line (Table 2; Figure 5). One fatality was counted from a feather spot and one from a whole specimen. The feather spot of a Eurasian collared dove (*Streptopelia decaocto*) was found directly under the powerline, and the source of death was considered to be a powerline collision. The whole specimen, a nestling house sparrow (*Passer domesticus*), was found directly below the powerlines and adjacent to an MVOH utility pole. This carcass exhibited two exterior wounds: on the foot and under the neck. Fatality searchers also observed several other live house sparrows perched on the adjacent utility tower. Although a nest was not observed, house sparrows frequently nest on the MVOH utility poles. If not from the adjacent utility pole, the nestling may have been predated from a nest on another nearby utility pole and then dropped. Therefore, the cause of death was considered to be predation.

Ten fatalities were counted along the Gen-tie Line (Table 2; Figure 6). All of these fatalities were counted from feather spots. More than half of these fatalities consisted of migratory songbirds, comprising an orange-crowned warbler (*Vermivora celata*), a common yellowthroat (*Geothlypis trichas*), a western tanager (*Piranga ludoviciana*), two yellow warblers (*Dendroica petechia*), and a cedar waxwing (*Bombycilla cedrorum*). All fatalities were found directly or nearly directly under the powerlines, and the causes of death were considered to be powerline collisions.

No fatalities were observed in the control plots, at the Evaporation Pond, or along the perimeter fence of the pond.

Section 4.0 Discussion

Overall, fatalities during the eighth quarter were the lowest observed since postconstruction fatality monitoring began in 2012. Likewise, the species that typically dominate our fatality detections at the Project, mourning doves and horned larks, had declined. Unlike in previous quarters, these species were also incidentally observed less frequently. It is possible that lower activity rates and overall lower fatality observations may be attributed to the ongoing drought. In the annual postconstruction fatality report we will examine annual avian point count data from the Project alongside other regional avian activity data to assess whether similar patterns have been observed elsewhere.

Consistent with the trend observed in previous quarters, the majority (92%, or 22 of 24) of postconstruction fatalities detected in the eighth quarter were counted from feather spots, making it difficult to definitively determine causes of death. Of the total number of fatalities, half could be attributed to a known cause (collision or predation) of mortality with a moderate degree of certainty (>50%), whereas the other half could not be attributed to a known cause of mortality.

Resident birds dominated fatality detections in the arrays, corresponding with the general avian species composition and nesting activity incidentally observed during fatality searches this quarter. Of the two resident species (house finches and horned larks) most detected as fatalities in the arrays, nesting activity was most frequently observed for house finches. Between May and July, ten house finch nests were incidentally observed in the torque tubes of the tracker units. Horned larks continued to be observed flocking and roosting among the panels during the eighth quarter. Those species most observed as active in the arrays in some capacity were also the most frequently documented fatalities in the arrays. As noted in previous quarterly reports, fatalities in the arrays are likely attributable to a combination of causes, including predation by resident predators and collisions.

Although overall fatality counts were low, migratory songbirds continue to be the most dominant avian group detected along the Gen-tie Line. During the eighth quarter, migratory songbirds accounted for half the fatalities detected along this power line. As discussed in the seventh quarterly report, we speculate that migratory songbirds interact with the Gen-tie Line more often, possibly because of the height of this structure and its low visibility at night, when most migratory songbirds typically migrate (Farnsworth et. al. 2004; Mabee and Cooper 2004; Watson et. al. 2011). We will provide more discussion and recommendations on this result in the annual postconstruction fatality report.

All feather spots found along the Gen-tie and MVOH Lines were located directly, or nearly directly, under these lines. Although assessing cause of death from feather spots is difficult, the locations of these fatalities suggest that they were caused by powerline collisions, and that the remains found were indicative of scavenging, rather than predation. Nevertheless, resident predators may contribute to some of these fatalities.

Although the full year of fatality searches for all Project elements is not yet complete, it appears that the Evaporation Pond, pond fence, and array perimeter fences contribute little to fatality detections at CVSR as few fatalities have been detected at these Project elements thus far.

Finally, no fatalities were detected in control plots during the eighth quarter. The lack of observed background mortality corresponds with the overall decrease in avian activity observed on the Project site.

Section 1. Introduction

Through adoption of Resolution #2011-119, the Board of Supervisors of San Luis Obispo County approved the California Valley Solar Ranch (CVSR) Project Conditional Use Permit (DRC 2008-00097) on 19 April 2011. The Conditional Use Permit (CUP) is subject to the Conditions of Approval (COAs) set forth in Exhibit 6 attached to the Resolution. The CUP allows the Applicant (High Plains Ranch II, LLC, and any successor in interest for the life of the CVSR Project) to construct and operate a 250-megawatt photovoltaic solar power plant on an approximately 1896-hectare (4685-acre) site, located mostly south of State Route 58, approximately 6.4 kilometers (4 miles) east of Soda Lake Road, immediately north of the village of California Valley, in the Shandon-Carrizo planning area of San Luis Obispo County.

To help satisfy COA #58 and address concern about possible effects of Project development on migratory and resident birds and bats, an Avian and Bat Protection Plan (ABPP) was developed by H. T. Harvey & Associates (HTH) (2011) in accordance with U.S. Fish and Wildlife Service guidelines (2010). The ABPP provides a framework for monitoring the potential direct and indirect impacts of the CVSR Project on all bat and bird species, with an emphasis on special-status species. For bats, the ABPP specifies using both roost counts in the area surrounding the Project and on-site acoustic monitoring to obtain an in-depth understanding of fluctuations in the local populations of sensitive bat species, as well as how different species are using the Project site and adjacent conservation lands. This document presents the results of bat monitoring conducted for the CVSR Project in 2014.

The Project region is characterized by open, xeric grasslands with rocky outcrops and scattered trees in peripheral areas. The bat species observed in the Carrizo Plain are consistent with those typically found regionally in this type of habitat (Johnston 1998a, 2007). Roosting habitat in the Carrizo Plain is suited primarily to crevice-roosting bats. Habitat for cave-roosting bats is restricted to a few mines and abandoned buildings to the west of the CVSR Project, in the Caliente Mountains where solitary Townsend's big-eared bats (*Corynorhinus townsendii*) occasionally occur. Foliage-roosting bats are not likely to occur in the Project area, except during spring and fall when hoary bats (*Lasiurus cinereus*) migrate through the area. Thus, species expected to reside in and around the CVSR Project throughout the year are the Pacific pallid bat (*Antrozous pallidus pacificus*; hereafter referred to as pallid bats), California mastiff bat (*Eumops perotis californicus*); hereafter referred to as mastiff bats, California myotis *(Myotis californicus*), western small-footed bat (*Myotis ciliolabrum*), canyon bat (*Parastrellus hesperus*), and Mexican free-tailed bat (*Tadarida brasiliensis mexicanus*). The fringed myotis (*Myotis thysanodes*) occurs in the Carrizo Plain National Monument, but is not expected to occur on the Project because suitable forested habitat is lacking. The Townsend's big-eared bat is expected to occur on the project only rarely, if at all, because of the scarcity of potential undisturbed roost habitat in the area. Although not expected to occur naturally, we have records of both big brown bats (*Eptesicus fuscus*) and Yuma myotis (*Myotis yumanensis*), which we have caught while mist-netting in the northern Carrizo Plain. These two species likely only exist in this area as a result of anthropogenic alterations to the landscape (e.g., artificial water sources and buildings), and are expected to occur very rarely on the Project. The pallid bat and California mastiff bat are designated Mammal Species of Special Concern and the Townsend's big-eared bat is designated a Candidate Threatened Species by the State of California (California Department of Fish and Game 2015) (Table 1).

Pursuant to the ABPP, HTH bat ecologists began installing and testing acoustic equipment in June 2012 and started collecting data in July 2012, to evaluate the potential effects on migratory and resident bat species caused by operational components of the Project. Likewise, we began systematic evaluations and monitoring of roost habitat within 10 kilometers (6.2 miles) of the Project in summer 2012. This annual report focuses on bat data collected from 1 January through 31 December 2014, but also includes data collected in 2012 and 2013 for statistical modeling purposes and analysis of trends in roost populations.

Table 1. Conservation Status of Bat Species Found in the CVSR Project Site Region

Species	U.S. Bureau of Land Management	California Department of Fish and Wildlife	U.S. Forest Service	Western Bat Working Group
Pallid bat *Antrozous pallidus*	Sensitive	Species of Special Concern	Sensitive	High Priority
California mastiff bat *Eumops perotis californicus*	Sensitive	Species of Special Concern	No status	High Priority
Mexican free-tailed bat *Tadarida brasiliensis mexicanus*	No status	No status	No status	Low Priority
Hoary bat *Lasiurus cinereus*	No status	No status	No status	Medium Priority
California myotis *Myotis californicus*	No Status	No status	No status	Low Priority
Fringed myotis *Myotis thysanodes*	Sensitive	No status	Sensitive	High Priority
Yuma myotis *Myotis yumanensis*	Sensitive	No status	No status	Low Priority*
Canyon bat *Parastrellus hesperus*	No Status	No status	No status	Low Priority
Big brown bat *Eptesicus fuscus*	No Status	No status	No status	Low Priority
Western small-footed bat *Myotis ciliolabrum*	Sensitive	No status	No status	Medium Priority
Townsend's big-eared bat *Corynorhinus townsendii*	Sensitive	Candidate Threatened (California Endangered Species Act)	Sensitive	High Priority

Source: California Department of Fish and Game 2015.
*Yuma myotis are listed as low priority in California, but medium priority in other ecoregions.

Section 2. Methods

2.1 Acoustic Monitoring

Bats use echolocation calls to detect prey and obstacles as they navigate across different landscapes. Although different species may demonstrate some degree of plasticity in their calls, acoustic parameters such as shape, duration, and minimum frequencies may be used to reliably identify species (Fenton et al. 1995). Today, two primary technologies exist for recording and analyzing bat calls: zero-crossing and full spectrum. Technology for viewing zero-crossing recordings is well developed; it is easy to quickly view and place species labels on thousands of calls at a time. However, full-spectrum technology provides more detail about specific call characteristics, which can sometimes be critical for identifying species with similar call parameters (Fenton 2000). Therefore, to assess relative bat activity in different areas of the CVSR Project, we used both AnaBat SD2s (Titley Scientific, Ballina, NSW, Australia), which are acoustic detectors that use zero-crossing technology, and Song Meter SM2 BATs (Wildlife Acoustics Inc., Concord, MA, USA), which are detectors with full-spectrum recording technology.

The ABPP monitoring plan was designed to allow for comparison of a year's worth of data between pre- and postconstruction levels of bat activity on the site. As defined by the ABPP, "postconstruction" is considered the period after Project commissioning. However, because the addition of constructed arrays (and even stacks of building material) to the environment during Project construction can affect both insect activity and bat activity by creating favorable windbreaks (Verboom and Huitema 1997; Grindal and Brigham 1999), it is likely that, biologically, this addition of structure, rather than the act of energizing the arrays, marks the distinctive point between pre- and postconstruction conditions. Therefore, for the purposes of our study, we considered individual solar arrays to be in a preconstruction state only before substantial building materials were moved into the area. The timing of construction activities and budgetary considerations prevented us from gathering a full year's worth of preconstruction data in the arrays; therefore, to more accurately record baseline levels of bat activity in natural areas, we installed additional bat detectors in Onsite Conservation Lands (i.e., lands near the arrays conserved as part of Project mitigation).

We deployed two detectors, one AnaBat SD2 (AnaBat), and one Song Meter SM2 BAT (Song Meter), in each of the nine arrays, and we deployed four Song Meters and four AnaBats in Onsite Conservation Lands (Figure 1). We staggered detector deployment across the year, and added new detectors as different construction areas became active (Figure 2). All detectors in Conservation Lands were deployed for at least 1 year (Figure 3). In arrays, we deployed detectors before the start of construction whenever possible, and all detectors were deployed for at least 1 year after the array in which they were located was commissioned.

As a naming convention, we used the prefix Arr to denote detectors in arrays, and the prefix Con to denote detectors in Conservation Lands. We used A or S to indicate which detectors were AnaBats and which were Song Meters. For all detectors in arrays, we included the number of the array at the end of the name to signify each detector's specific location. For detectors in Conservation Lands, we commonly used the number from the closest array, but we deviated from this convention in the following cases: ConAN refers to the AnaBat north of State Route 58, ConSO refers to the Song Meter in Conservation Lands by the operations and maintenance (O&M) facilities, and ConAF refers to the AnaBat next to an abandoned farmhouse. For clarity, we use this naming convention throughout the rest of the document to refer to specific detectors.

Figure 1. Locations of Acoustic Detectors

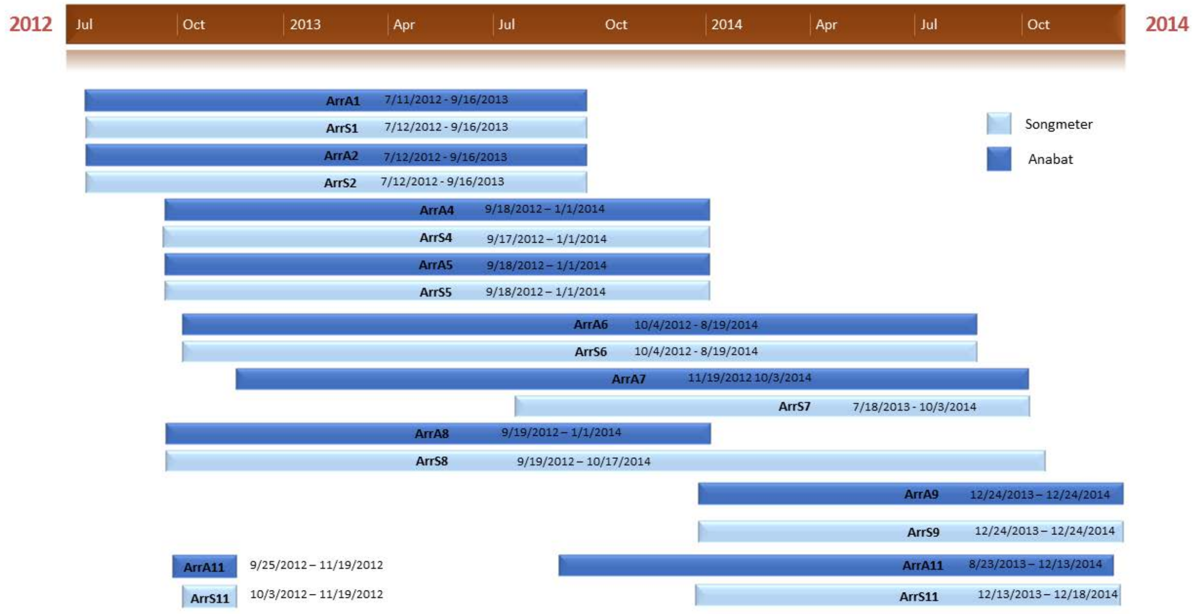

Figure 2. Deployment Dates of Acoustic Bat Detectors in Arrays

[1] Detector naming convention:
- Arr refers to detectors in arrays.
- S and A denote the type of detector, Song Meter or AnaBat.
- The final number indicates the array location.

[2] Preconstruction periods for Array 6 ran from 4 October–12 December 2012.

Preconstruction periods for Array 11 ran from 25 September and 3 October 2012 to 19 November 2012 for ArrA11 and ArrS11, respectively.

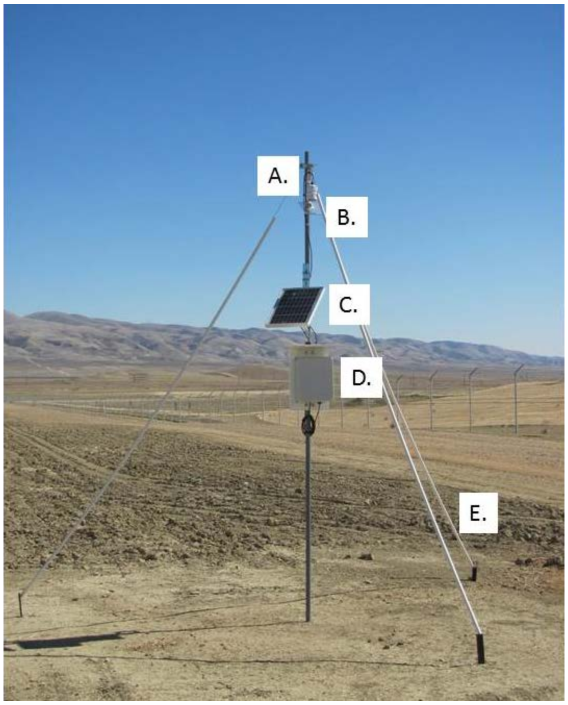
Figure 3. Deployment Dates of Acoustic Bat Detectors in Onsite Conservation Lands

Detector naming convention:
- Con refers to detectors in Conservation Lands.
- S and A denote the type of detector, Song Meter or AnaBat.
- The final character indicates specific location: a number indicates an array location or the nearest landmark for those in Conservation Lands; F refers to an abandoned farmhouse on site; O refers to the O&M facility area; N refers to north of State Route 58.

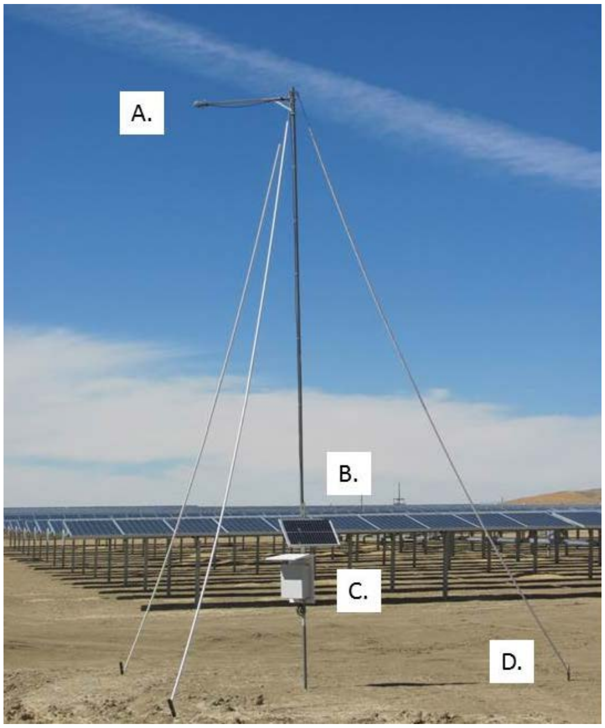
We deployed AnaBat detectors on 10-foot poles, each with a small, 20-watt photovoltaic panel to power the detector. Each pole was tethered to the ground using guy-wires. The wires were covered with PVC piping to make the wires more visible and prevent avian collisions. The AnaBat units were placed inside a weatherproof box and attached to the pole using U-clamps. The AnaBats were powered by solar panels, and both the wire for the solar panel and the wire for the microphones were threaded through the bottom of the weatherproof box. Microphones were positioned facing downward to provide weatherproofing. A reflector plate was angled at 45° from horizontal and placed directly underneath each microphone (Figure 4a). AnaBats were set to record on a nightly basis from 17:00 to 07:00 (5 PM to 7 AM). A subset of detectors (ConA5, ArrA1, ArrA2, and ConAF) was deployed with temperature loggers attached. Each AnaBat in this subset was programmed with its Universal Transverse Mercator (UTM) coordinates, and was set to record from sunset to sunrise, based on location.

We deployed Song Meters on 20-foot poles (Figure 4b). The Song Meters were also set to run on external power supplied by solar panels attached to the poles. Each pole was tethered to the ground using guy-wires. The wires were covered with PVC piping to make the wires more visible and prevent avian collisions. The Song Meter units were placed inside a weatherproof box and attached to the pole using U-clamps. The Song Meters were powered by solar panels, and both the wire for the solar panel and the wire for the microphones were threaded through the bottom of the weatherproof box. We programmed Song Meters according to the default settings provided in the Song Meter SM2 BAT instruction manual. The UTM coordinates were set for each detector, and the Song Meters were set to record from sunset to sunrise, based on their location.

We positioned detectors so that microphones were pointing into the arrays and as close as possible to the edge of each array without casting a shadow onto the panels.



(a) AnaBat SD2. This configuration consisted of: A. microphone; B. reflector plate; C. solar panel; D. AnaBat SD2 and weatherproof case; and E. guy-wire cables and stakes.



(b) Song Meter SM2BAT. This configuration consisted of: A. microphone and bird deterrent caging; B. external solar panel power source; C. Song Meter and weatherproof case; and D. guy-wire cables and stakes.

Figure 4. Monitoring Station Configurations

2.2 Acoustic Analysis

We manually classified all bat acoustic files collected. For the AnaBat data, we used a library of known bat calls to develop a set of automatic filters based on the unique call parameters (e.g., minimum frequency and duration) of different species found in the Carrizo Plain. These filters were used to quickly sort and batch like calls together in AnaLook, v.3.9c (Corben 2011).

Whenever possible, we identified bats to species level based on the acoustic parameters of shape, minimum frequency, duration, and/or critical frequency. Calls that we could not identify to species were classified as unknown. When possible, we classified unknown call files according to the lowest frequency of the calls (i.e., unknown 20-kilohertz [kHz], unknown 30-kHz, and unknown 40-kHz+). When calls in a file were weak or shifted in frequency, we classified them as unknown, with no subcategory.

The first filter we ran was designed to select for files that contained low-frequency calls. We expected Mexican free-tailed bats, pallid bats, and mastiff bats to be included in this group. Because Mexican free-tailed bats were the most abundant of these three bats, we created a filter that was designed to conservatively select only Mexican free-tailed bats. All files that passed the filter were marked and moved into a folder named by species. The remaining files in the low-frequency folder were unknown 20-kHz bats, unknown 30-kHz bats, pallid bats, and a few residual Mexican free-tailed bats.

Likewise, we created a filter designed to filter out files with high-frequency calls. We expected canyon bats, California myotis, and western small-footed bats to be in this group. Because canyon bats and California myotis both have calls with higher minimum frequencies than western small-footed bats, we created a combined filter designed to filter out both California myotis bats and canyon bats. All files that passed this secondary filter were marked and moved into a folder named by species. The remaining files in the high-frequency folder were unknown 40-kHz bats and western small-footed bats.

Once we had created species groups, we manually scanned each group folder and marked noise files for deletion. We also labelled any files that showed poor call quality or indicated species other than the species targeted by a given filter. We deleted all previously marked calls, then marked all labeled calls, and reversed the marks to apply a global header change so that species labels could be attached to all unlabeled files in a folder at one time. We then summed activity levels using the Count Labels tool in AnaLook.

Song Meter data were analyzed in Sonobat v.3.0, US West (Szewczak 2010), callViewer, v.18.0 (Skowronski and Fenton 2008), and AnaLook, v.3.9c (Corben 2011). As a time-saving measure, we converted all Song Meter calls to both zero-crossing and .wav files. This allowed us to move quickly through easily identifiable calls in AnaLook and mark other files for a second look in full-spectrum.

Among the species we analyzed, the echolocation calls of hoary bats and Mexican free-tailed bats are difficult to discriminate because they share similar measurements of minimum frequency and duration. These species also both demonstrate a variety of call shapes, which can be similar to one another; however, some calls may be classified to species through examination of the power spectrum (Skowronski and Fenton 2008), which shows the strength of the signal versus time. This method cannot be used to discriminate species when analyzing zero-crossing AnaBat files, because of constraints associated with this recording technology. Therefore, particularly when looking at AnaBat call files, hoary bat and Mexican free-tailed bat calls are difficult to discriminate. To determine whether or not both species are present on the site, in 2012, we examined 100 Song Meter call files classified as Mexican free-tailed bats/hoary bats from October, when both species are considered migratory, and examined the shape of the power spectrums associated with each Song Meter file to make species discriminations. In this sample, nearly all of the calls were identified as Mexican free-tailed bats and only a few were identified as hoary bats. Hoary bats are a foliage roosting species; therefore, the Carrizo Plain is unlikely to provide suitable habitat for them, and any detections of this bat will likely occur during the spring and fall migratory periods. Because the vast majority of calls from Mexican free-tailed bats and hoary bats overlap, we did not attempt to determine the relative abundance of each species for our analyses. Therefore, throughout the remainder of the report, we will refer to this group as Mexican free-tailed bats, with the understanding that some small number of hoary bats may fall under this label.

Bat calls cannot be used to identify individuals, but the number of calls is commonly used as an index of overall activity at a site (Kunz et al. 1996). We quantified bat activity separately for each species classification by presence/absence within 1-minute periods per night; this method provides more accurate assessments of bat activity than traditional methods of counting individual passes (Miller 2001).

2.3 Roost Observations

To locate bat roosts on and in the vicinity of the CVSR Project, we used both systematic searches and radio telemetry. At each known roost site, we attempted to make a minimum of two counts per summer: one count in early summer during the prevolant period, or before the young of the year are able to fly, and a second count in late summer, during the postvolant period, after the young of the year are able to fly, but before the maternity colonies disperse.

In June–August 2012, we located two potential maternity roosts in rocky outcrops using a combination of radio telemetry and systematic site investigations. One suspected roost was located on U.S. Bureau of Land Management land, but further investigation in 2012 and 2013 revealed that it did not contain a maternity colony. A second roost was found and confirmed on private property. In 2013 and 2014, we went back to the roost on private property. Also in 2013, we received information about a second maternity colony, located in a building, and we monitored this roost through the end of 2014. We used two tally counters each to keep track of (1) how many bats flew out from an emergence spot and (2) how many bats flew back into the same crevice. For the purpose of comparison, we subtracted the number of bats recorded by the second tally counter from the number of bats recorded by the first tally counter.

2.4 Statistical Analysis

For descriptive statistics, we plotted the average number of minutes of activity per night by month for known species for all sites, and relative bat activity for known species or frequency group for the year. These were plotted only for 2014 acoustic data, when arrays were built and fully operational. We refer to Conservation Lands and operational arrays as "preconstruction" and "postconstruction" areas, respectively, to maintain consistency within discussions of parameter estimates.

We conducted all other statistical analyses in R (R v.2.13.1; R Development Core Team 2011). We used both boxplots and Cleveland dotplots to detect outliers. During our initial analysis, it became clear that the AnaBat at the farmhouse recorded significantly more activity than any other detector, likely because trees provide additional habitat structure around this site (Verboom and Huitema 1997; Jantzen and Fenton 2013). Among all the detector sites, trees are unique to this location, so we removed this detector's data from our analysis.

We set all of our explanatory variables (year, month, individual detector location, and construction status) as categorical factors. We expected microphone type to have only a slight effect on the overall interpretation of bat activity, because Song Meters and AnaBats record at similar rates, particularly for lower frequencies (Adams et al. 2012), so we did not include this variable in our analysis.

In total, we ran six models: one for total bat activity on the site, and one model for each species group detected (with hoary bats and Mexican free-tailed bats in one group). Because the data were non-normal and showed signs of heterogeneity, we applied a log transformation (x + 1) to each dataset. We applied generalized least-squares models using the nlme package (Pinheiro et al. 2014). Because the variance of the data differed as a function of individual detector location, we applied an identity variance function to the data to allow the variance to differ by individual detector location. We modeled the activity of each group or species as follows:

Activity = month + construction status + individual detector location + year

We used backward, stepwise selection and removed variables that did not contribute significantly to the model one at a time until all remaining variables were significant.

No calls were recorded from California myotis at ArrS9. This microphone was removed from analysis for this species' model because this is an outlier. Additionally, the model is structured to measure differences in variances among microphones and won't run without some variance.

Section 3. Results

3.1 Acoustic Analysis

In 2014, detectors were operational for 3154 detector nights, ranging from 132 nights recorded at ArrA6 to 357 nights recorded at ConS8. We detected a total of 36,739 minutes (612.3 hours) of bat activity for known species (calls that could be identified to species) and frequency groups. We detected a total of 11,321 minutes (188.7 hours) of bat activity for unknown species. With the exception of western small-footed bats, the average number of minutes of activity for known species was less than 3 minutes per night each month (Figure 5). The average minutes of activity for western small-footed bats peaked at 7.1 minutes per night in August. Likewise, the average number of minutes of activity for California myotis and canyon bats peaked between August and September. Mexican free-tailed bat activity peaked in May and again in September. The average number of calls/minute each month was fairly constant for pallid bats and was never greater than 0.5 minute per night each month. For the year, western small-footed bats accounted for the highest percentage, 38.7%, of total bat activity (Figure 6). Mexican free-tailed bats and canyon bats accounted for 25.6% and 16.4% of the total bat activity, respectively. California myotis and pallid bats accounted for less than 12% of the total activity, and unknown frequency groups/species combined accounted for less than 8% of the total activity for the year.

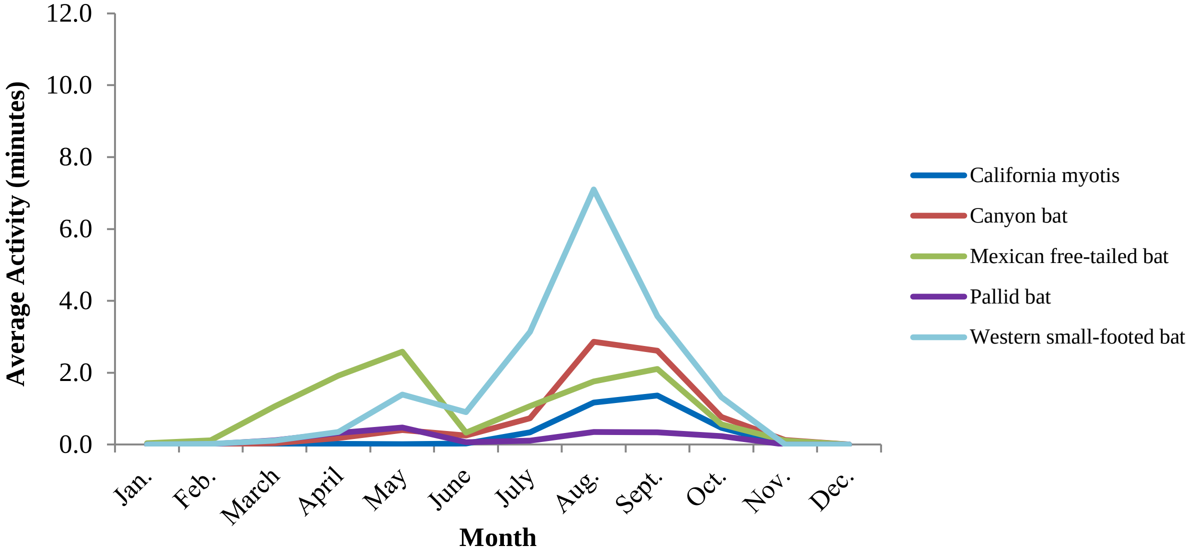


Figure 5. Average Number of Minutes of Activity per Night for Each of Five Species, by Month, in 2014

Total nights of recordings per month are as follows: January = 365, February = 352, March = 362, April = 278, May = 257, June = 277, July = 304, August = 282, September = 242, October = 139, November = 167, and December = 129.

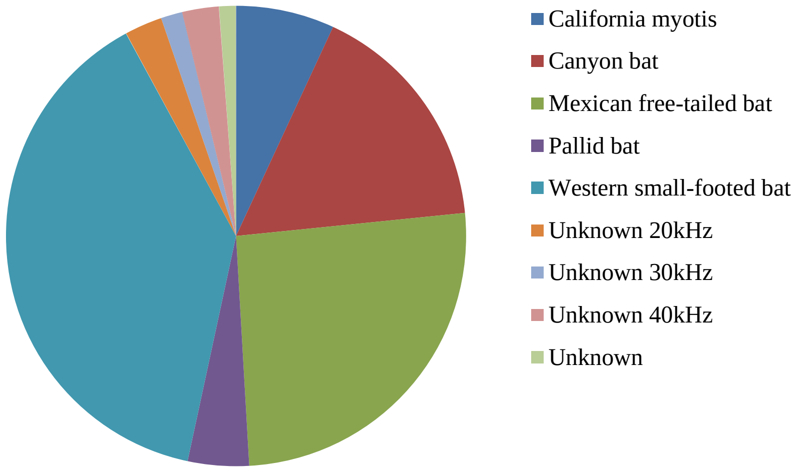

Figure 6. Relative Bat Activity by Species or Frequency Group for 2014

Total minutes recorded for each species or frequency group are as follows: California myotis = 851, canyon bat = 2026, Mexican free-tailed bat = 3159, pallid bat = 526, western small-footed bat = 4759, unknown 20-kHz = 325, unknown 30-kHz = 178, unknown 40-kHz = 316, and unknown = 146.

Total Bat Activity on Site. Total bat activity on site was significantly affected by year, month, and individual detector location ($P<0.05$). Activity was significantly higher in the summer months, compared to the winter months ($P<0.05$). The highest activity occurred in 2012, with significantly decreased activity in 2013 and 2014 (Appendix A, Table A-1).

California Myotis Activity. The activity of California myotis was affected by month and individual detector location ($P<0.05$). Compared to summer months, activity was significantly lower in winter months (Appendix A, Table A-2).

Canyon Bat Activity. Month, individual detector location, year, and construction status all affected the activity of canyon bats ($P<0.05$). Compared to preconstruction areas, canyon bat activity was higher in arrays ($P<0.05$). The activity of these bats was lower in 2013 and 2014 compared to 2012 ($P<0.05$). Compared to most winter months, activity was significantly higher in summer months (Appendix A, Table A-3).

Mexican Free-tailed Bat Activity. Month, individual detector location, and year all affected the activity of Mexican free-tailed bats ($P<0.05$). The activity of these bats was lower in 2013 and 2014 compared to 2012 ($P<0.05$). As a whole, activity was significantly lower in winter months, compared to spring and summer months (Appendix A, Table A-4).

Pallid Bat Activity. The activity of pallid bats was affected by month, individual detector location, year, and construction status ($P<0.05$). The activity of pallid bats was lower in 2013 and 2014, compared to 2012 ($P <$

0.05). In contrast to our findings regarding other bat species, the activity of pallid bats was lower in arrays, compared to preconstruction areas ($P<0.05$). As a whole, activity was significantly lower in winter months, compared to summer months (Appendix A, Table A-5).

Western Small-footed Bat Activity. Month, individual detector location, and year affected the activity of western small-footed bats ($P<0.05$). As a whole, activity was significantly lower in winter months, compared to summer months (Appendix A, Table A-6).

3.2 Roost Counts

3.2.1 Rocky Outcrops on Private Land

Our primary study site consists of a network of rocky outcrops with variable heights (3 – 12 meters) surrounding a private residence on both the east and west sides of the house. The western outcrop is approximately 85 meters (279 feet) wide. The eastern outcrop is more fragmented, but also measures approximately 85 meters wide. Bats are known to inhabit both outcrops.

We observed bats emerging from four areas, which we labeled Roosts A, B, C, and D. These roosts were located in rock outcrops that are within 200 meters of each other. Roost A is located in the western outcrop. Roosts B, C, and D are located in the eastern outcrop, on the east-facing, west-facing, and south-facing sides of this outcrop, respectively. Although roosts were not labeled as such in 2012 or 2013, the defined areas are the same and are used in this report to make clear comparisons across all years (Table 2).

In 2012, we counted bats emerging from Roost A, although the high location of the roost in the rock made it difficult to see individuals at the point of emergence. We counted 68 individuals emerging from this roost on 24 July and 26 individuals emerging on 3 September 2012.

As reported in the 2013 annual bat report (HTH 2014), we conducted roost counts on 29 May, 4 June, and 18 July 2013. On 29 May, we counted no bats emerging from Roost A. We counted 65 bats and 39 bats emerging from Roosts B and C, respectively. The moon phase on 29 May was waning gibbous, so the sky was fairly bright. On 4 June, we did not perform a count at Roost A because bats had not been observed in this area during the recent previous surveys, and it is difficult to get an accurate count from this location, owing to its height. We counted no bats emerging from Roost B, but we counted 26 bats and 23 bats emerging from Roosts C and D, respectively. The moon phase on 4 June was waning crescent, so the sky was fairly dark. On 18 July we did not perform a count at Roost A for reasons cited previously. We counted no bats at Roost B or D. The gibbous moon on 18 July provided for bright conditions.

In 2014, roost count numbers were very low. We conducted emergence counts on 30 June and 29 August 2014. On 30 June, we counted no bats at Roost A or D. We counted three bats each at Roost B and C. On 19 July the sky was fairly bright because the moon was in the gibbous phase. On 29 August we did not survey Roost A. On 29 August, we observed three bats each emerging from Roosts C and D, but no bats were observed emerging from Roost B. The sky was fairly dark because the moon was in the crescent phase on 29 August.

Table 2. Roost Count Results for Rocky Outcrop Roost on Private Land in 2013 and 2014

Date	Location	Number of Bats	Volancy Period	Moon Phase
7/24/2012	Roost A	68	Postvolant	Waxing crescent stage/dark
9/3/2012	Roost A	26	Postvolant	Waning gibbous/bright
5/29/2013	Roost A	0	Prevolant	Waning gibbous stage/bright
5/29/2013	Roost B	65		
5/29/2013	Roost C	39		
6/4/2013	Roost A*	n/a	Prevolant	Waning crescent/dark
6/4/2013	Roost B	0		
6/4/2013	Roost C	26		
6/4/2013	Roost D	23		
7/18/2013	Roost A*	n/a	Postvolant	Waxing gibbous/bright
7/18/2013	Roost B	0		
7/18/2013	Roost C	5		
7/18/2013	Roost D	0		
6/30/2014	Roost A	0	Prevolant	Waning gibbous stage/bright
6/30/2014	Roost B	0		
6/30/2014	Roost C	5		
6/30/2014	Roost D	0		
8/29/2014	Roost A*	n/a	Postvolant	Waxing crescent/dark
8/29/2014	Roost B	0		
8/29/2014	Roost C	3		
8/29/2014	Roost D	3		

Notes:
Roost A = located in western outcrop.
Roost B = located in east-facing side of eastern outcrop.
Roost C = located in west-facing side of eastern outcrop.
Roost D = located in south-facing side of eastern outcrop.
*n/a = Not surveyed.

3.2.2 Building Roost

We first visited this site on 31 May 2013. We counted 47 pallid bats emerging. The moon was in a waning gibbous stage, so the sky was somewhat bright. Because this was not our primary roost study site, we did not return for a postvolant count. We revisited this site on 30 June 2014 for a prevolant count and recorded 46 individuals emerging from this roost. On 28 August 2014, we revisited this site for a postvolant count and recorded 25 bats.

Section 4. Discussion

4.1 Acoustic Analysis

Overall, western small-footed bats were the most frequently detected species, with canyon bats the third most frequently detected species, and slightly less activity for California myotis on the Project in 2014. Western small-footed bats, canyon bats, and California myotis are often common in arid and semiarid habitats, and typically roost in cracks or crevices in rocky outcrops (Holloway and Barclay 2001; Findley and Traut 1970). Given the availability of suitable habitat in the region, our results are consistent with the life history of these two species, and all species that we detected are common and well-documented as occurring in the Carrizo Plain.

We did not detect Yuma myotis or big brown bats on our Project study site, but these are expected to occur only rarely in the Carrizo Plain, and may not occur as far south in the valley as the Project. Although one previous study noted silver-haired bats (*Lasionycteris noctivagans*) occurring in the Carrizo Plain with 95% certainty (Althouse and Mead 2014), big brown bats and silver-haired bats have nearly identical echolocation calls. Reliable discrimination of silver-haired bats often relies on maximum frequencies, which quickly fade out owing to environmental attenuation (Betts 1998). Thus, based on our professional knowledge from previous surveys in the area and of this species' habitat needs, and despite the findings of Althouse and Mead, we consider it unlikely that silver-haired bats occur in the Carrizo Plain.

4.1.1 Annual Changes and Seasonal Trends

Mexican free-tailed bats were the second most frequently detected species in 2014. This species demonstrated peaks in activity in the spring and fall. In the southwest, Mexican free-tailed bats exhibit strong migration patterns in the spring and fall, which is closely tied to winter hibernation and maternity-season activity (Villa and Cockrum 1962; McCracken and Gustin. 1991). Mexican free-tailed bats also migrate short distances from inland areas of California in the summer to more coastal areas of the state in winter (Johnston 1998b). Although these local migration patterns are poorly understood, seasonal movements to coastal areas of California are probably associated with mild winter temperatures there. Although Mexican free-tailed bats are not closely associated with arid habitats, their overall activity levels and seasonal abundance on the Project is likely associated with their migratory movements. At the Project, the detected pulses of Mexican free-tailed bat activity in the spring and fall coincided with the expected timing of these short-distance migrations.

We also found peaks in activity in the fall for California myotis, canyon bats and western small-footed bats. By August, most young are volant and capable of foraging independently, and maternity colonies are beginning to disperse. Peak activity detected during this time likely reflects these general seasonal patterns.

We found that overall activity for pallid bats was low, compared with the other known species, throughout the year. Detections were likely lower because of the hunting strategy used by the species. In contrast to other bat species that locate prey through a quick succession of echolocation pulses referred to as feeding buzzes, pallid bats listen passively for insect vocalizations to locate and isolate their prey (Fuzessery et al. 1993). Although pallid bats still rely on echolocation for navigational purposes, this hunting strategy results in fewer vocalizations, compared with other species. Because acoustic monitoring records echolocation calls, actual pallid bat activity is likely higher than the acoustic data suggests.

We found that all bat species had decreased activity in 2013 and 2014 compared to 2012, and this is likely related to the regional drought. Moderate drought conditions were prevalent in the CVSR Project area by January 2013, extreme drought conditions by January 2014, and exceptional drought conditions by the end of 2014, as defined by the National Drought Monitor (National Drought Mitigation Center 2014). The overall declines in bat populations are mirrored by the trends observed for other species over the past 3 years, including burrowing owls (*Athene cunicularia*), San Joaquin kit foxes (*Vulpes macrotis mutica*), songbirds, and raptors (HTH 2015a, 2015b).

Greif and Siemers (2010) suggested that bats, particularly naïve juveniles, may try to drink from smooth surfaces, such as flat solar panels, that they encounter in the wild. However, over the course of 2 years, no bat fatalities have been found during regular fatality searches of the Project.

4.1.2 Effects of Arrays

We found no relationship between total bat activity and the presence or absence of arrays; however, we found significant increases or declines in specific species' responses to the array areas. As found in previous years, we found increased activity of canyon bats in the Project arrays, compared to preconstruction areas (including Conservation Lands). One explanation for this trend relates to the echolocation call characteristics of this species. Call characteristics help to suit different species of bats to different foraging habitats (Fenton 1990; Schnitzler and Kalko 2001; Müller et al. 2012). Canyon bats have an intermediate call type that combines a frequency-modulated call characteristic, or a call that covers a wide span of frequencies, with a narrowband characteristic, or a call that covers a narrow range of frequencies. These types of calls are commonly seen in species that forage most effectively along edge-type habitats (Fenton 1990), and it is probable that they are using the edges created by the array panels. Several other species, including the California myotis and western small-footed bat, have similar call types but did not exhibit increases in activity in array areas. Perhaps there are unknown nuances in the behaviors of these species that might explain these differences.

We found that the activity of pallid bats decreased in arrays, compared to preconstruction areas (including Conservation Lands), and this likely reflects the foraging habits of this species. Pallid bats typically forage at low heights in the range of 0.5–2.5 meters (1.6–8.2 feet) (O'Shea and Vaughan 1977). Therefore, it is plausible that the fences surrounding the arrays act as a foraging barrier for them (i.e., they change directions when they fly close to a fence rather than flying over the fence.

The relationships between different species and site construction status in 2013 held true in 2014, giving further support to the strength of these relationships. One exception to this, however, was Mexican free-tailed bats, which were previously found to have significantly higher activity inside array (postconstruction) areas, compared to preconstruction areas. The construction status term was dropped from the model in the 2014 analysis because its P-value was >0.05 (*P*=0.051). The exclusion of this term highlights one of the problems of backward step model selection: the arbitrary choice of the level of significance can result in excluding terms that would have been included if an alternative level had been used (i.e., 10% instead of 5%). Although this term likely exerts some influence on bat activity, the effect was not strong enough to include in the full model, and we cannot be sure if the apparent significance of this effect in 2013, and the apparent lack of significance in 2014, is a real change or is an artifact of the model selection process. However, residual analysis did not reveal any trends to indicate that it was a strong effect that should be included, regardless of P-value; therefore, we consider the effect of construction status on activity levels of Mexican free-tailed bats to be borderline.

4.2 Roost Counts

The size and number of boulders in the roost complex located on private land limited the accuracy of our exit counts because we found multiple exit points from multiple outcroppings. Pallid bats are known to switch roosts frequently (Lewis 1996; Johnston et al. 2006), and these particular pallid bats likely switch among multiple roosts that are close to one another, making it difficult to determine net changes in population size.

In contrast, the roost site at the building, which we first visited in 2013, has one controlled access point, and is much more isolated from other potential roosts. Both of these factors make this roost a more reliable location from which to take data—this is shown by the similar numbers of bats recorded for the prevolant counts between 2013 and 2014 (47 and 46, respectively).

The size and number of boulders in the roost complex located on private land limited the accuracy of our exit counts because we found multiple exit points from multiple outcroppings. Pallid bats are known to switch roosts frequently (Lewis 1996; Johnston et al. 2006), and these particular pallid bats likely switch among multiple roosts that are close to one another, making it difficult to determine net changes in population size. In contrast, the roost site at the building, which we first visited in 2013, has one controlled access point, and is much more isolated from other potential roosts. Both of these factors make this roost a more reliable location from which to take data—this is reflected by the steady numbers of the prevolant counts between 2013 and 2014 (47 and 46, respectively).

Besides the apparent overall changes in colony size caused by roost switching, there was a large drop between the prevolant counts that were made at the roost on private land in 2013 and 2014. This drop may have been related, in part, to the timing of the moon phase during the roost counts. While we sought to account for moon phase during all roost counts, it was not always feasible to schedule counts under the same light conditions. Moon phase can affect roost counts, because bat activity tends to be lower on brightly lit nights

(O'Shea and Vaughn 1977). However, we observed higher prevolant numbers during the brightly lit night in 2013 and lower prevolant numbers during the dimly lit night in 2014. Conversely, we observed higher prevolant numbers during the darkly lit night in 2013 than during the brightly lit night in 2014. Therefore, moon phase did not likely affect our roost exit counts greatly, nor is the difference between the counts for 2013 and 2014 likely due to moon phase.

While the timing of the observed decline in roost counts corresponds to the construction of the Project, it is more likely that the drop in counts may be an effect of environmental conditions. The region has experienced a severe drought over the past 2 years. The decreased rainfall has caused trophic-level effects: there was lower vegetative cover in 2014 (HTH 2014b), and fewer insects were observed by many HTH field staff in the region in 2013 and 2014. Drought conditions also may have decreased the survival rates of both adult and subadult bats (Frick et al. 2007, 2010). The effects of the drought, combined with frequent roost switching, and moon phase, made it difficult to determine direct population effects, and what, if any, effects are directly attributable to the Project's construction. The final year of roost counts (2015) will be conducted at this site, as well as at the Building, to hopefully provide more insight on population trends for pallid bats, 3 years after the CVSR Project began.

Executive Summary

Project Overview

The California Valley Solar Ranch Project (CVSR Project) is a 250-megawatt solar photovoltaic energy facility located within an approximately 4685-acre site (Project site) in eastern San Luis Obispo County, California (Figure 1). The facility is owned and operated by High Plains Ranch II, LLC (HPR II). The Conditional Use Permit for the CVSR Project required that an Avian and Bat Protection Plan be prepared and implemented to monitor the impacts of the CVSR Project on birds and bats after construction. In compliance with the resultant Avian and Bat Protection Plan, avian and bat fatality searches were conducted from 6 June 2012 through 17 November 2014. This report represents the final avian and bat fatality report, and covers the monitoring results of searcher-efficiency trials, carcass-persistence trials, repeat fatality searches, regular weekly fatality searches, and incidental observations of fatalities from 16 August 2013 to 17 November 2014.

Methods

H. T. Harvey & Associates (HTH) biologists conducted weekly surveys in the following CVSR Project elements: Arrays 1, 2, 4, 5, 6, 7, 8, 9, 11, and in 20% of all associated perimeter fence areas, the Medium-voltage Overhead (MVOH) Line, the Generation-tie (Gen-tie) Line, and the Evaporation Pond. During the reporting period, all arrays were surveyed each week at 20% of their total area, with the exception of Arrays 1 and 2, which were surveyed with 100% coverage through the end of December 2013, at which time they too were surveyed at 20% of their total area. Additionally, to help identify the proportion of fatalities found that could be attributed to natural mortality rates, we surveyed control plots, located in Conservation Lands surrounding the CVSR Project site.

All fatalities were classified as either carcasses or feather spots. Feather spots consisted of groups of feathers composed of at least two or more primary flight feathers, five or more tail feathers, or 10 or more feathers of any type concentrated together in an area 1 square meter (m^2) or smaller (Smallwood 2007); feathers with significant skin or flesh, or with any bone attached, were considered fatality detections but were not necessarily considered feather spots.

In addition to performing weekly searches, HTH biologists conducted a series of repeat searches: 5-day repeats, in which biologists searched the same subset of a Project element for 5 consecutive days, and 1-day repeat searches, in which biologists searched a subset of an area that was searched 1 day previously by either 5-day repeat searchers or weekly searchers. The purpose of these repeat searches was to check the efficiency of searchers and evaluate the consistency of results; however, as reported herein, not all of the repeat searches proved necessary, and they were discontinued at the end of December 2013.

To estimate the rate of avian and bat fatalities occurring on the site, we used Huso's Fatality Estimator (2011). In formulating a fatality estimate, it was necessary to determine (1) the rate of scavenging that occurs on the site, and (2) how well searchers find different-size carcasses in different amounts of vegetation cover. These determinations were made by (1) planting fresh carcasses of birds of various sizes and placing camera traps on them to identify scavenger species and the exact time of carcass removal, and (2) planting both carcasses and feather spots of different sizes in different vegetation classes while regular weekly and repeat searches were taking place. Searcher-efficiency and carcass-removal rates were then used to adjust the annual count of fatalities to arrive at a site-wide fatality estimate.

We used background fatality rates estimated from searches of control plots within onsite Conservation Lands to adjust fatality rates within arrays. This enabled us to estimate mean background-adjusted fatality rates for the CVSR Project that represent fatalities that cannot be explained by background fatalities alone. This estimate was substantially less than the total unadjusted fatality rates within arrays. Our method used bootstrap resampling of observed data to estimate the mean and 90% confidence intervals for background-adjusted per-tracker unit fatality rates.

Results and Discussion

During the period of 16 August 2013 to 17 November 2014, a total of 453 avian fatalities, of 36 identified species and 5 unknown species groups, were detected. A total of 364 fatalities were found during standardized weekly searches. This number includes four clearance fatalities (fatalities found on the initial search of an area, which cannot be reliably aged or attributed to Project-related causes). A total of 54 fatalities were found during standardized 5-day and 1-day repeat searches. This number includes 18 clearance fatalities. A total of 35 fatalities were found incidentally. Two of the incidental fatalities were found in onsite Conservation Lands, and these, along with the four weekly clearance and 18 repeat clearance fatalities, were not used in any analyses in this report. That left an effective sample size of 429 fatalities that were used for analyses in this report.

Of the 429 fatalities found in Project elements and control plots during this reporting period, the cause of death for the majority (80.9%) could not be reliably discerned. Seventy-three (17.0%) were believed to have died as a result of a collision (65 with powerlines, 7 with solar panels, and 1 with a perimeter fence). Two deaths were believed to be caused by electrocution (0.5%). Six (1.4%) were believed to have been caused by predation, and one (0.2%) was believed to have been caused by disease.

Across Project elements, the majority (85.3%) of all fatalities were of resident species. The highest number of fatalities of migrants was found along the Gen-tie Line, where migratory species accounted for 21.5% of all fatalities. Seasonal variation was apparent in the pattern of fatalities found in both the arrays and along the Gen-tie Line. Fatalities found in the arrays peaked in the winter, whereas Gen-tie Line fatalities peaked in the late summer and fall.

For both carcass-persistence and searcher-efficiency trials, data were grouped over the entire postconstruction period to create a more robust sample size for the purposes of using the Fatality Estimator. One specimen was placed for each persistence or searcher efficiency trial. Between 15 October 2012 and 11 March 2014, we conducted carcass-persistence trials with 206 specimens. Eleven trial carcasses were excluded because the persistence data collected were insufficient (i.e., carcasses were collected by staff after the initial scavenging event), leaving an effective sample size of 195 carcasses. The carcass-persistence trials included 96 small carcasses and 99 large carcasses. Assuming conservatively that carcasses would not persist past the 6-week trial period, mean carcass persistence over the entire year was 9.3 days for small carcasses and 22.2 days for large carcasses.

In total, we planted 434 fatalities for searcher-efficiency trials. Three fatality plants were removed by scavengers, leaving an effective sample size of 431 (113 small and 98 large feather spots and 113 small and 107 large carcasses). Overall searcher efficiency was 50.8%, but varied from 57.3% to 44.5% in easy and moderate-visibility areas, respectively. Searcher efficiency also varied by size and fatality type: 72.9% of all large carcasses were found and 41.6% of all small carcasses were found, whereas 65.3% of all large feather spots were found and only 26.5% of all small feather spots were found.

During the period of 7 November 2013 to 6 November 2014 (the period used in the Fatality Estimator, representing one full year where weekly fatality searches occurred across all Project elements), there were an estimated 126 fatalities from known causes that occurred on the Project site (90% confidence interval: 106–155). There were not enough fatalities with known or suspected causes of death in the arrays to run a fatality estimate reflecting cause of death (N=2), but the estimate of fatalities per tracker in the arrays, for fatalities with unknown or natural causes of death, was 2.24 (90% confidence interval: 1.83–2.87). In the control plots, this estimate was 1.72 (90% confidence interval: 1.05–2.68).

For this same period, we estimated the mean background-adjusted per-tracker fatality rate to be 0.51 (90% confidence interval:-0.83-1.81) for one full year. The mean annual background-adjusted fatality estimate within arrays encompassing approximately 1176 acres at the CVSR project containing 1032 tracker units for the period of 7 November 2013 to 6 November 2014 was 526 fatalities (0.51 fatalities per tracker unit x 1032 tracker units).

Recommendations

During the course of this fatality monitoring study, we have identified areas where further research is needed to guide the design of future fatality monitoring studies at utility-scale solar facilities. The following recommendations outline research areas and measures that we believe are important.

- Background mortality should be assessed using a spatially balanced study employing control plots similar in size, layout, and overall total area to the developed project site.
- Focused research on the causes of feather spots and the average number of feather spots created from a single fatality should be considered.

- If site-wide fatality monitoring is deemed necessary, monitoring should start once the full project becomes operational and for at least one year. Fatality monitoring survey design, including spatial coverage requirements and survey frequency can be optimized after the collection of preliminary data.
- Intensive daily repeat fatality surveys are not necessary to conduct fatality estimates and are only recommended when required to link timing of fatalities to specific events (e.g., weather patterns or operational changes).
- Avian use studies should consider bird census techniques that are potentially more effective in documenting species richness and relative abundance of birds in project areas that will be covered by arrays, such as line transect methods.
- Projects incorporating high-tension powerlines should assess whether the project site is located in an important route for migratory songbirds.
- To assess fatalities along linear project features such as powerlines, study designs should incorporate linear controls, to provide background mortality rates for such features.
- To the extent practicable, powerlines should not be placed over wetland features, where large numbers of birds may roost and nest.
- We recommend that necropsies be performed on a subsample of carcasses to provide confirmation of the cause of the fatality.
- The use of scent dogs should be considered to increase the likelihood of detecting rare events and increase the accuracy and narrow the confidence level of fatality estimates, especially in areas with high density vegetation.
- Feather spots should be incorporated into bias-trial protocols to produce more robust fatality estimates and to provide more comparable industry-wide fatality estimates, especially for studies with longer search intervals.

Section 1.0 Introduction

On 19 April 2011, through adoption of Resolution #2011-119, the Board of Supervisors of San Luis Obispo County (the County) approved the California Valley Solar Ranch Project (CVSR Project) Conditional Use Permit (DRC 2008-00097). The CVSR Project is a 250-megawatt solar photovoltaic energy facility located within an approximately 4685-acre site (Project site) in eastern San Luis Obispo County, California (Figure 1). The facility is owned and operated by High Plains Ranch II, LLC (HPR II).

Before construction of the Project, there were concerns about the anticipated impacts that the Project might have on birds and bats. In particular, it was predicted that obligate waterbirds may mistake the panels for water and be attracted to the solar arrays; waterbirds are sometimes found in black-top parking lots or on roads, and some solar facilities have reported finding waterbird fatalities (Horvath et al. 2009; Grippo et al. 2014; Kagan et al. 2014). There was also concern that birds and bats could collide with panels (McCrary et al. 1986; Grippo et al. 2014). Although bird and bat mortality has been well documented at wind energy projects (Arnett et al. 2008; Baerwald and Barclay 2009), the level of CVSR's probable impacts was not certain. Therefore, H. T. Harvey & Associates (HTH) developed an Avian and Bat Protection Plan (ABPP) (HTH 2011) for the Project as required by the County as part of its Conditions of Approval (COAs), set forth in Exhibit 6 attached to the Resolution. As elements of the Project became operational, and continuing after the full completion of construction, HTH ecologists have implemented the *Avian and Bat Fatality Monitoring Plan for the California Valley Solar Ranch* (Fatality Monitoring Plan) (Appendix A in HTH 2011), conducting weekly fatality searches and additional searches to document impacts on birds and bats.

As required in COA #58, HTH, on behalf of HPR II, has submitted one annual report and eight quarterly reports detailing all Project-related bird or bat deaths or injuries detected during the monitoring study defined by the Fatality Monitoring Plan. This document represents the final fatality report for the Project. As required in the Fatality Monitoring Plan, this Final Postconstruction Fatality Report documents the results of postconstruction monitoring for 1 full year after completion of the Project. It summarizes the results of fatalities found since the end of the first annual reporting period (15 August 2013), integrating results from the most recent quarter of monitoring, and discusses the complete study period for the Project, where appropriate.

One of the main goals of the monitoring effort was to estimate the numbers of fatalities associated with different Project elements. In addition to performing regular weekly searches, we conducted searcher-efficiency trials to estimate the percentage of fatalities of different sizes found by searchers in both short and tall vegetation. To calculate the persistence of fatalities in the environment, we also conducted carcass-persistence trials. The values we derived from both types of trial were used in tandem with the results of the weekly searches to estimate ranges of fatalities associated with different Project elements. Additionally, to obtain an estimate of background mortality levels, we conducted controlled searches in control plots located on onsite Conservation Lands. We calculated levels of fatalities associated with various Project elements, using the Fatality Estimator (Huso 2011) to extrapolate from our survey data to the entire Project. The date range for all fatality estimates is based on one full year where weekly fatality searches occurred across all Project elements, from 7 November 2013 to 6 November 2014.

California Valley Solar Ranch
ABPP Final Postconstruction Fatality Report

Figure 1. Project Site with Gen-tie Line, MVOH Line, Evaporation Pond, Arrays, and Control Plots

This Final Postconstruction Fatality Report is organized as follows:

- Section 2 describes our field and statistical methods.
- Section 3 presents the results of weekly and repeat fatality searches, describes trends and patterns in the monitoring results; and provides estimates of fatalities by Project element and cause of death.
- Section 4 draws comparisons between our results and the results of fatality searches conducted in other regions and industries.
- Section 5 lists recommendations for future studies.
- Section 6 lists the references cited in this report.
- Appendices A and B list avian species used in the searcher-efficiency and carcass-persistence trials.
- Appendix C presents data from weekly fatality searches for the period of 16 August 2013 to 17 November 2014.
- Appendices D and E present data from repeat searches for the period of 16 August 2013 to 31 December 2013 (after which repeat searches were discontinued).
- Appendix F lists fatalities that were incidentally observed in the period of 16 August 2013 to 17 November 2014.
- Appendix G includes errata for data reported in the first annual postconstruction fatality report (HTH 2014a); revisions were made to correct errors, erroneous omissions, or any other changes that were made to the dataset. Notes are included summarizing the reason for the change.

Section 2.0 Methods

This section presents the methods we used to conduct weekly and repeat fatality searches, collect data from incidental observations, and perform carcass-removal and searcher-efficiency trials. Project elements searched as part of this study were the Generation-tie (Gen-tie) Line; the Medium-voltage Overhead (MVOH) Line; Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11; the array perimeter fences; control plots; and the Evaporation Pond.

2.1 Field Methods

2.1.1 Weekly Fatality Searches

To estimate the total number of fatalities associated with different Project elements, we conducted a series of weekly fatality searches on different Project elements. Because the construction of different Project elements was completed at different times, fatality searches began at varying times of year, depending on the Project element searched (Table 1).

2.1.1.1 Field Search Methods

Weekly fatality searches were performed for the Gen-tie Line; MVOH Line; Evaporation Pond; Arrays 1, 2, 4, 5, 6, 7, 8, 9, and 11; and the associated control plots and fences for each array. The study design involved sampling 100% of the Gen-tie Line, MVOH Line, and Evaporation Pond. Twenty percent of Arrays 4, 5, 6, 7, 8, 9, and 11 were sampled, as was 20% of their respective fences. Arrays 1 and 2 and their associated fences were searched at 100% for the first year of fatality searches, after which (beginning in January 2014) they were searched at 20%, and four control plots were removed to reflect the decreased search effort in these areas. Each week, we selected random start locations for each Project element using a random number generator. Random selection was based on tower numbers (for the Gen-tie Line), line segment (for the MVOH Line), numbered array corners (for the solar arrays), and numbered fence corners (for the array perimeter fences).

A team of two biologists searched a 30-meter (m)-wide transect centered under the complete length of the Gen-tie Line. Because of the relatively shorter height of the MVOH Line, it was assumed that carcasses would have less potential to distribute over a wide area (HTH 2011); therefore, the transect area along the entire length of the MVOH Line was only 18 m wide. Each person searched half the transect width and half the tower or pole radial areas for both the Gen-tie and MVOH Lines. On the Gen-tie Line, each person searched a 15-m-wide transect for large birds and a 6-m-wide transect for small birds and bats. On the MVOH Line, each person searched a 9-m-wide transect for small and large birds.

Table 1. Fatality Search Commencement Dates by Project Element

Project Element	Date Fatality Searches Began
Gen-tie Line	6 June 2012
Array 1[1]	20 September 2012
Array 2 (Serengeti portion only)[2]	25 September 2012
Array 1 and 2 fence[1]	25 September 2012
Array 2 control plots	30 October 2012
Array 1 control plot	1 November 2012
Array 2 North (including Serengeti) and South[1, 2]	27 November 2012
Array 8 (20% sample)	7 January 2013
Array 4 (20% sample)	9 January 2013
Array 5 and fence (20% sample)	9 January 2013
Array 4 fence (20% sample)	16 January 2013
MVOH Line	30 January 2013
Array 8 control plots	4 February 2013
Array 4 control plots	6 February 2013
Array 8 fence (20% sample)	20 May 2013
Array 6 and fence (20% sample) and control plots	30 September 2013
Array 7 and fence (20% sample) and control plots	10 October 2013
Array 9 and fence (20% sample)	6 November 2013
Array 11 and fence (20% sample), and control plots	6 November 2013
Evaporation Pond	11 November 2013

Notes:
[1] Sampling reduced to 20% of total array area (starting 2 January and 7 January 2014 for Arrays 2 and 1, respectively).
[2] The Serengeti portion of Array 2 was searched separately only until 27 November 2012 (3 days).

In the arrays, biologists searched tracker units in teams of two. In each tracker unit, biologists walked into every other row of panels and visually scanned both the row walked and each adjacent row. To avoid crossing the drive arms of the tracker units, searchers turned around upon reaching the drive arm, and continued to scan the next row as they proceeded out of the row. Thus, although searchers walked only every other row, they visually scanned adjacent rows to ensure full coverage (Figure 2).

Control plots were randomly placed in adjacent onsite Conservation Lands to measure the level of background mortality. Control plots were designed specifically for comparing background fatality rates to fatality rates within arrays by making them equivalent to the size of a typical SunPower Oasis tracker unit (i.e., equivalent to 18 rows of solar panels, with 40 panels to a row), which measures approximately 79.9 m by 42.8 m (3416 m^2). Six aggregated tracker units comprise a typical tracker block that generates 1.5 megawatts. We used pin flags or wooden stakes to delineate mock panel trackers on the control plots, and searchers followed the same pattern and procedure used for searching the arrays. We did not establish control plots for the 20% sample of Arrays 5, 6, and 9 because the 20% search area for these arrays contained too few trackers to meet the control plot establishment guidelines set forth in the Fatality Monitoring Plan (Appendix A in HTH 2011; the guideline is one control plot [defined in the plan as having the same spatial scale as 2 aggregated tracker blocks, or 12 tracker units] for every 16 tracker blocks [96 tracker units] searched).

Twenty percent of the total fence length was surveyed by one biologist. Each week, the biologist walked the inside portion of the fence while scanning a 6-m-wide belt centered on the fence. In some cases, the fences were not completely built until after weekly searches had already commenced. In these instances, fences were included as part of the regular search routine only after they were completely installed.

Because searches were conducted only on designated days as a part of the search protocol, make-up searches were not conducted if the search day was missed because of inclement weather, holidays, or maintenance work. In estimating the total number of fatalities, the fatality model accounted for search intervals of different lengths due to missed searches (e.g., if a weekly search day was cancelled because of rain, the search effort would resume the following week, and for that search, the interval was 14 days, not 7 days).

Figure 2: Fatality Search Pattern

2.1.1.2 Data Collection

We documented a fatality event each time a carcass or a feather spot was found. We considered a feather spot a fatality if it had at least two or more primary flight feathers, five or more tail feathers, or ten or more feathers of any type concentrated together in an area 1 square meter (m^2) or smaller (Smallwood 2007). We defined the number of feathers required to constitute a fatality using definitions employed in other fatality studies at wind farms (e.g., Gruver et al. 2009; Erickson 2009; Smallwood et al. 2010). Additionally, feather spots not meeting these requirements but containing flesh, blood, or bone were also considered fatalities.

During fatality searches, we occasionally encountered avian roost areas where signs of preening and molting were evident. Preening and molting spots typically have fewer feathers and are more spread out than feather spots associated with fatalities. Also, roosting areas rarely contain primary or secondary feathers, but are often dotted with droppings. In the solar arrays, we regularly observed flocks of mourning doves (*Zenaida macroura*) and horned larks (*Eremophila alpestris*) roosting. Mourning doves exhibit a complex molt strategy that can occur year-round and includes preformative, prealternate, and definitive prebasic molts (Otis et al. 2008). Likewise, horned lark adults and first-year birds undergo a definitive prebasic molt at the end of the breeding season (typically the end of July) (Beason 1995). Searchers used their biological knowledge to determine whether or not feathers from mourning doves, horned larks, or other species known to be in a molt period should be recorded as a fatality. No data were taken on molt or roost-spot feathers.

When a fatality was detected, we assigned the fatality a unique incident number and recorded data on the fatality and the substrate in which it was found. Incident numbers were written as follows: YYYYMMDD-##, consisting of the year, month, day, and a unique number assigned to each searcher. Each searcher recorded a unique set of numbers, so data can be traced back to individual searchers. To verify species identifications, we took photographs of each fatality and, when necessary, consulted Scott and McFarland's *Bird Feathers: A Guide to North American Species* (2010). We also consulted our feather reference collection, prepared from positively identified fatalities collected on the site over the course of Project monitoring. For each fatality, we recorded location (using Universal Transverse Mercator [UTM] coordinates), time found, taxon, four-letter alpha code, carcass condition, parts found, number and types of feathers, suspected cause of death, and estimated time since death. Whenever possible, we recorded information about the age and sex of the fatality, as well as scavenger type. Additionally, we gathered information on the size and spread of the feather spot and the surrounding substrate, vegetation height, and percent vegetation cover, as well as whether the fatality occurred in an array row walked by a searcher, or in a neighboring row (for fatalities found in the arrays). All carcasses and feather spots discovered by regular weekly searchers were removed.

The suspected cause of death was assessed for all fatalities and assigned to one of the following classes: collision, electrocution, predation, disease, or unknown. It was then further assigned a "Level of Certainty for Suspected Cause" category, as defined in the Migratory Bird Special Purpose Utility Salvage Permit (SPUT) for the Project (issued by the U.S. Fish and Wildlife Service [USFWS] on 10 March 2014 [permit number MB02733B-0]). Level of certainty was assigned as follows: Observed = 100%; Valid = >90%; Probable = >50%; Possible = <50%; or

Unknown/Not Applicable. To make the assessment, searchers examined all carcasses for signs of injury or illness, and assigned a cause of death using the following assumptions:

- Possible solar panel or powerline collision: If fatalities were found in arrays or under powerlines, we assigned collision as the cause of death with >90% certainty if carcasses had injuries consistent with an impact. We assigned collision as the cause of death with >50% certainty if feather spots or carcasses had no noticeable injuries but were found within 10 feet of powerlines. In arrays, we assigned collision as the cause of death with <50% certainty if feathers or flesh were stuck to solar panels, or if smudge marks or imprints, as from an impact, were observed on a panel.

- Electrocution: For fatalities near the MVOH Line, we assigned electrocution as the cause of death with >90% certainty if carcasses had visible injuries consistent with electrocution (e.g., singed feathers, burns on feet, or curled leg scales). Likewise, we assigned the same cause of death and level of certainty to a few fatalities based on circumstantial evidence (e.g., a breaker tripped during a recent rain event for an unknown reason, and a bird nesting on an overhead wire pole was found dead shortly afterward).

- Predation: We assigned predation as the cause of death with >90% certainty if birds were found impaled on tumbleweeds, fence lines or other structures. For decapitated carcasses found in any Project element, we assigned predation as the cause of death with <50% certainty. Fatalities found at sites regularly used by predators (e.g., at a plucking post), as indicated by old remains, were assumed to be predated with >50% certainty.

- Disease: We assigned this cause of death with >50% certainty if a carcass was emaciated or otherwise appeared unhealthy (e.g., if it had growths typical of avian pox).

- Unknown: Fatalities were assigned the designation of unknown cause of death when there was no compelling evidence to indicate how these fatalities occurred (e.g., carcasses had no obvious signs of injuries or illness, or body parts or entrails were present on solar panels but there were no visible imprints or smudge marks that allowed us to distinguish between predation and collision).

2.1.2 Repeat Searches

A series of repeat searches was designed to provide a verification of the results of weekly searches. Repeat searches were designed to create a shorter search interval that would allow carcasses with a short scavenging time to be more readily found and identified. Because repeat searches were intensive, they covered less area than the regular weekly searches. After the first annual report, it became apparent that avian fatalities, particularly long-lasting feather spots, accounted for the bulk of the findings. Likewise, the low number of trackers that were searched during each 5-day repeat search caused confidence intervals on these independent fatality estimates to be greatly inflated, compared to the estimates produced using weekly search data. For these reasons, the utility of repeat searches was greatly reduced, and the decision was made to cease all repeat searches (both 5-day and 1-day repeat searches) from 1 January 2014 onward. The methods used for the repeat searches, conducted before 1 January 2014, are summarized below.

2.1.2.1 5-Day Repeat Searches

Five-day repeats were conducted on all Project elements subject to regular weekly searches, with the exception of the Gen-tie Line, which was not included in the 5-day repeat searches because small birds and bats were assumed to be unlikely to strike high-tension powerlines. All other Project elements were subjected to 5-day repeat searches once every 4 weeks.

During each 5-day repeat search period, searchers covered a quarter of the total area covered during regular weekly searches (i.e., 25% of Arrays 1, 2, and the MVOH Line, and 5% of Arrays 4, 5, 6, 7, 8, 9, and 11), and the same areas were searched for 5 consecutive days. Because of the small size of the Evaporation Pond, searchers walked the entire perimeter of the pond during repeat searches. However, due to the large size of Array 2, 5-day repeat searches of Array 2 Serengeti were conducted separately from those of Array 2 North and South.

When possible, 5-day repeat searches were conducted in areas separate from regular weekly searches, to keep the search interval at a constant span of 7 days for all weekly search areas. In Arrays 1 and 2, however, overlapping search areas were unavoidable because weekly searches encompassed 100% of the arrays.

The first day of each 5-day repeat search was treated as a clearance search, and all fatalities found on the first day were removed from further analysis. Data for fatalities was collected in the same way as weekly search data, with the following exception: feather spots and scavenged carcasses were monitored throughout the search period, and notes were made regarding persistence. All remaining feather spots were collected on the fifth day of the 5-day repeats. For intact carcasses, cameras traps were placed near the carcasses to monitor persistence past the 5-day span of the repeat searches, with the intention of collecting additional data for carcass-persistence trials; however, due to technical issues, camera traps did not function properly during these trials and the data could not be incorporated.

2.1.2.2 1-Day Repeat Searches

One-day repeat searches covered a randomly selected block representing 25% of all elements (i.e., arrays, fences, and control plots) searched in the original weekly or 5-day repeat searches. Blocks were searched on the day following regular weekly searches, every other week (semimonthly), and after each 5-day repeat search, on either the last day of the 5-day search or 1 day after its completion.

2.1.3 Incidental Fatalities

Fatalities were sometimes found outside of regularly searched areas, both by CVSR Project personnel and HTH biologists. When this happened, fatality data were recorded and the fatality was collected in the same manner as if it were found during a weekly search. These fatalities could not be included in the site-wide fatality estimate, however, because the lack of a regular search interval made it impossible to accurately quantify the search effort for the area and the probability of finding the fatality. Nonetheless, all incidental fatalities are reported here, in the SPUT reports, and in reports for other Project salvage collection permits.

2.1.4 Carcass-persistence Trials

Carcasses decompose at rates that are influenced by environmental conditions, and carcasses and feather spots are also moved and dispersed by wind and scavengers. To calculate the number of fatalities that might be available for searchers to find in a given period, it is necessary to estimate the total persistence rates of carcasses. Scavenger species and density vary by region, so site-specific carcass-persistence trials must be conducted to accurately estimate fatality rates.

For our carcass-persistence trials, we acquired avian carcasses from the onsite fatality searches and a local wildlife rehabilitation center. We also collected them opportunistically (e.g., we collected road-killed birds) under State and federal salvage permits. Whenever possible, we used species that naturally occur on the site or in the surrounding area, and limited the handling of carcasses to reduce transfer of foreign scents. We categorized all carcasses into one of two sizes: small (≤100 grams [g]) and large (>100 g). For the purposes of the descriptive statistics and fatality estimates provided in this report, trial data from the first year and second year (between 15 October 2012 and 11 March 2014) are grouped together to provide a more robust fatality estimate. Of the 206 carcasses that we placed for carcass-persistence trials, 101 were large and 105 were small (Appendix B).

To avoid “scavenger swamping” (saturating our study area with more carcasses than resident scavengers are able to remove) (Smallwood et al. 2010), we limited the number of carcasses present in a search area at one time to four. We dropped carcasses from shoulder height and allowed them to fall naturally to the ground. We recorded each carcass location with a Global Positioning System (GPS) unit, and noted the direction and distance to the nearest tower (when carcasses were placed along the Gen-tie Line) or tracker number (when carcasses were placed in arrays). We placed Bushnell Trophy Cameras (Model 119436) within 1–1.5 m of the carcass on a t-post, facing north to avoid allowing sunlight to shine directly into the camera lens. We programmed cameras to take three date- and time-stamped photographs in quick succession after each trigger event; each camera had a 1-second refractory period between pictures.

We checked each carcass and the camera batteries and memory storage cards at least once per week, for up to 6 weeks or until the carcass was scavenged. We classified the carcass as “removed” if the carcass could not be located, or if there were fewer than ten feathers of any type or fewer than two primary feathers remaining. To classify feather spots, we used criteria similar to those used by the regular weekly searchers. Therefore, we classified the scavenging outcome as “not removed” if there were ten or more feathers of any type, two or more primary feathers, or any flesh or bone remaining. If the carcass was no longer in front of the camera and was not readily apparent, we searched the surrounding area using a spiral search pattern. We started the search at the camera’s location and spiraled out to 30 m from the camera. If the carcass had been moved to a new location within the search area, but was intact, we repositioned the camera on the carcass in its new location.

During the first year of our study, we collected all remaining feathers and signs of the carcass after the initial scavenging event. However, after the first annual report, it became apparent that, because of the high proportion of feather spots found on site, it was necessary to estimate the full persistence time for carcasses, rather than the time to scavenging (in this report, use of the term *carcass persistence* rather than *carcass removal* reflects this broader focus). Therefore, in this document we report the time to scavenging as the time to the last scavenging event, and for scavenger species, we report the scavenger that resulted in the carcass's removal or conversion to a feather spot. In nine trials, carcasses were collected after the initial scavenging event, when partial or nearly whole carcasses remained behind. We exclude the results of these trials because they lack complete persistence data and we have no basis for estimating the time to the last scavenging event. Additionally, to accurately estimate total persistence, we conducted 30 feather spot persistence trials, in different vegetation heights, to determine appropriate adjustment factors to add to the persistence time of carcasses that were scavenged but left feather spots behind. We monitored each feather spot on a weekly basis for up to 4 weeks. To calculate the adjustment factor, we took the midpoint from the time between the last check when the feather spot was present and the first check when the feather spot was absent. We averaged these persistence times by vegetation class and added them to the total persistence time for all carcasses that left feather spots behind after scavenging.

For 28 of the carcasses that were removed and left no feather spot, the time of scavenging was not captured on camera. For the purpose of our descriptive statistics, we calculated the midpoint between the last photograph in which the carcass was present and the first photograph in which it was absent, and used that as the time of scavenging, to yield the total persistence time.

2.1.5 Searcher-efficiency Trials

Not all fatalities deposited in a search area are observed by searchers because detection is inherently imperfect, being influenced by topography, vegetation, fatality size and type, and the number of fatalities removed by scavengers (Thompson 1994). To determine how efficient searchers are at detecting fatalities, we conducted a series of searcher-efficiency trials, in which we placed trial fatalities (*fatality plants*) throughout the fatality search areas and calculated the average number of trial fatalities found by searchers.

For the purposes of the descriptive statistics and fatality estimates provided in this report, trials from the first year and second year are grouped together to provide a more robust fatality estimate. Therefore, we report on a total of 52 days of searcher-efficiency trials, starting 5 September 2012 and ending 31 July 2014, and representing the entire postconstruction study period.

We used both carcasses and feather spots in various amounts of vegetation cover throughout the year to characterize separate rates of searcher efficiency for fatality size (large or small), fatality type (carcass or feather spot), and visibility. Trial fatalities included specimens of common species found on the CVSR Project site and suitable proxy specimens salvaged from a local wildlife rehabilitation center (Appendix A). To avoid harming scavengers, euthanized specimens were not used for bias trials. In total, we planted 434 fatalities for searcher efficiency trials. Three fatality plants were removed by scavengers, leaving an effective sample size of 431 (113 small and 98 large feather spots, and 113 small and 107 large carcasses).

We assigned each species of carcass to one of two sizes (small or large) based on weight (i.e., small = ≤100 g; large = >100 g), as defined in *The Sibley Guide to Birds* (Sibley 2000). We also assigned a size to each feather spot based on spread of feathers. A small feather spot was defined as feathers from a small or large bird, scattered in a ≤20-square-centimeter (cm^2) area; a large feather spot was defined as feathers from a small or large bird scattered in an area >20 cm^2. In total, we classified all fatality plants into one of four size classes: (small feather spot, large feather spot, small carcass, or large carcass).

We originally categorized visibility into one of three classes: Easy, Moderate, or Difficult, based on a combination of vegetation height and percent vegetation cover (Table 2; Figure 3) within a 1-m^2 area surrounding each fatality plant. However, because the Difficult visibility class was rarely present (N=5), for all analyses, we lumped Moderate and Difficult visibility classes together in the High vegetation height category.

Table 2. Visibility Classifications Assigned to Categories of Vegetation Height and Percent Cover

Vegetation Height (Low <25 cm, Medium 25-50 cm, High >50)	Vegetation Cover (%)	Visibility Classification
Low	0–50	**Easy**
Low	50–100	**Moderate**
Medium	0–25	**Easy**
Medium	25–100	**Moderate**
High	0–50	**Moderate**
High	50–100	**Difficult**

In the field, we used a combination of haphazard and random, stratified sampling to determine the placement of each fatality plant. Haphazard sampling was incorporated to ensure that a representative number of trial fatalities were placed in all visibility classifications. We marked each fatality plant discreetly with tape or flagging so that searchers would know to report their findings as part of the controlled searcher-efficiency trial. We arrived approximately 1 hour in advance of the searchers so that we could set out fatality plants without alerting searchers that they were being tested. We recorded a GPS point for each fatality plant, and assigned it to a visibility group. Searchers contacted the efficiency-trial biologist as they discovered trial plants, and all plants were removed from the field once the fatality search was completed.

a) Easy Visibility **b) Moderate Visibility**

Figure 3. Photographic Examples of Easy (a) and Moderate (b) Visibility Classes for Feather Spots (Top Two Panels) and Carcasses (Bottom Two Panels), Based on Vegetation Height and Percent Cover

2.2 Statistical Methods

Animals die at an unknown rate, which must be inferred from regular searches of a site. Secondly, fatalities persist for varying amounts of time and are imperfectly detected by searchers. For these reasons, it is often inappropriate to draw conclusions based on the raw number of fatalities in an open system. The need to accurately estimate fatalities given these variables has driven the development of several fatality estimation statistical methods (e.g., see Johnson et al. 2003; Smallwood 2007; and Huso 2011). All of these fatality estimation models are based around several common themes; in particular, all such models are designed to infer information about the total number of fatalities or total fatality "population" based on fatalities that are found. In an open system, the true total number of fatalities is unknown and cannot be determined, but fatality estimators use information based on average scavenging times and average searcher efficiency to form a number range (confidence interval) that likely contains the true number of total fatalities for a given site. The interval can be broadened or constrained based on the level of confidence desired. For this report, we use 90% confidence intervals for all fatality estimates. This means there is a 90% probability, based on our sample size that the true number of fatalities falls within our estimated range.

Because fatality estimates are based on the total number of fatalities found, there is an inherent bias when low numbers of fatalities are discovered. This is often referred to as *sampling bias*; it refers to the fact that small sample sizes may include outliers that are not representative of the wider population (in this case, the total number of fatalities that occur). As the number of fatalities found grows larger, the number, size, and species of fatalities should become more representative of the population, and fatality estimates become more accurate. Throughout this report, we urge caution in the interpretation of estimates based on small sample sizes; also, we did not calculate estimates based on data representing fewer than five fatalities.

As mentioned above, fatality estimation methods share a similar underlying premise. Generally, the fatality estimation formula for a given site may be written as:

$$F = C/rp,$$

where the number of fatalities, F, is the quotient of the number of carcasses found, C, over the product of carcasses left unscavenged, r, and the proportion that an observer sees, p (Huso 2011).

The inputs for r and p are estimated in subgroups of covariates that influence the detectability and persistence of each carcass, such as carcass size, vegetation height, and stage of decay or scavenging (i.e., feather spot versus carcass). Given the tendency for many fatality estimation models to underestimate site-wide fatalities, we chose to use a fatality estimator written by Huso (2011), which was shown to outperform previously developed models by more accurately accounting for imperfect detectability. This model, the Fatality Estimator, was developed to estimate fatalities primarily for wind energy projects; however, it can be applied to other types of sites, including powerlines and solar projects (Huso 2011). The Fatality Estimator uses the conceptual framework of fatalities, combined with bootstrapping from models of r and p, to calculate variances and confidence intervals for the estimate of total fatalities. (*Bootstrapping* is a statistical method used to create a distribution to assign measures of variance to estimates when the underlying distribution of data is either unknown or cannot be represented algebraically (Efron and Tibshirani 1986)—bootstrapping resamples the data, by taking a subsample of the entire data set several thousand times to create a distribution that may be used to infer information about the sample mean).

2.2.1 Estimating Carcass-persistence Rates

Measurements of carcass-persistence rates, r, typically include one or more censoring values. A *censoring value* is used in statistics when a value is only partially known. For example, if a carcass was checked on day 7 and was present, and was checked again on day 10, but was found to be missing, then the date of scavenging is unknown, and an interval censor would be used. Because we used camera traps, the majority of scavenging times were known precisely, and the data were not censored. However, when cameras failed to record the moment of scavenging, we applied interval censoring. Likewise, because feather spots were collected after scavenging events, a right censor was applied to trial carcasses that resulted in feather spots (right censors are typically used when the carcass or feather spot is collected prior to the end of the trial). Finally, owing to camera malfunctions, no photographs were taken of some carcasses prior to scavenging. In these cases, the carcasses and all evidence of the fatalities were removed before the first field observation. The time to scavenging and total persistence time for these carcasses was calculated as the midpoint from the time of placement to the time of the first field check, and a left censor was applied in the model.

There are four commonly used survival model distributions that can be used in the Fatality Estimator for a value of *r:* exponential, Weibull, loglogistic, and lognormal. These four distributions have different rates and shapes of decay curves that attempt to model the survival of carcasses over a given search interval. Because the time of death for detected fatalities is usually unknown, the probability of persistence cannot be calculated exactly for each carcass, but it can be estimated from the selected survival model and bootstrapped to obtain a range of estimates of *r* for each carcass.

We modeled our data using a series of models based on each of these four distributions. For each distribution, we compared models with and without explanatory variables. (An *explanatory variable* is any data set of interest that may have an influential relationship on the dependent variable, or measured outcome, of a study.) Specifically, for each distribution, we compared the following possible models: the null model, which contains no explanatory variables, a model controlling for season as an explanatory variable, a model controlling for size as an explanatory variable, and a model controlling for both season and size as explanatory variables. This resulted in four models for each distribution, for a total of 16 models.

To rank the fit of each survival model to our carcass-persistence trial data, we used Akaike's Information Criterion adjusted for sample size (AICc) (Akaike 1973). AIC and AICc are typically used to compare the relative fit of different models to a dataset. Although the absolute value of AICc may vary, the difference in AICc values among models provides information about which model is most statistically supported. The model with the lowest AICc value is typically held to be most supported by the data, but any model with a change in AICc values of less than 2 from the "best model" is considered to have strong evidence supporting it (Burnham and Anderson 2004).

2.2.2 Estimating Searcher-efficiency Rates

Searcher efficiency, or the proportion of fatalities that an observer sees, *p*, is represented most simply by the following equation:

$$p = \frac{NumberObserved}{NumberAvailable}$$

We compared four models for this dataset: the null model, a model containing size class as an explanatory variable, a model containing visibility class as an explanatory variable, and a model containing both size class and visibility class as explanatory variables.

2.2.3 Estimating Fatalities on the Project Site

The Fatality Estimator bootstrapping procedure calculates an adjusted fatality value for every fatality found based on the search interval, searcher efficiency, and carcass persistence. Because fatalities of different species and different-size feather spots are found in different vegetation heights and percent cover, fatality estimates based on different data sets with the same number of total fatalities can yield very different results. Fatalities found in tall grass, for example, are considered more difficult to find, based on the searcher-efficiency rates calculated at the CVSR Project. Therefore, fatalities found in tall grass are weighted more heavily in the overall estimate.

Within the Fatality Estimator, the bootstrapped values are automatically summed, and a total estimate and 90% confidence intervals are calculated for the Project element and each covariate combination assigned. The Fatality Estimator was developed for wind energy projects, and used individual wind turbines as the sample unit of replication. To apply this tool to the CVSR Project, we used tracker units instead of turbines as the sample unit. For the overhead lines, for which the entire length was sampled, we set the entire feature as the sample unit. For the fences, we made an estimate from the 6411.2-m length searched during weekly fatality searches as a unit, and extrapolated from the estimate to represent the total fence length of 32056 m.

Although the majority of fatalities were included in the fatality estimates, some did not meet the underlying assumptions of the fatality estimate model. Fatalities deemed older than the search interval (i.e., fatalities missed during previous searches) were not included in the Fatality Estimator because rates of imperfect efficiency (i.e., <100%) are already accounted for in the model, and including these old fatalities would falsely inflate estimates. Likewise, incidental fatalities were not included in the Fatality Estimator because they were found outside the defined search effort. Clearance fatalities more than 1 day old (>24 hours) were also excluded from estimates because time since death could not be reliably established.

When possible, we calculated fatality estimates by fatality class [a size designation of small ≤100g, or large >100 g. based on average size of species as defined in *The Sibley Guide to Birds* (Sibley 2000)], season, and cause of death; however, small sample sizes (N<5) sometimes did not allow for estimates to be calculated for all of these explanatory variables.

The date range for all fatality estimates is based on one full year where weekly fatality searches occurred across all Project elements, from 7 November 2013 to 6 November 2014. Although Arrays 1 and 2 were searched at 100% until the end of December 2013, fatalities found in trackers outside the 20% area that was established in January 2014 were excluded from all estimates.

2.2.4 Applying Control Plot Data to Adjust Fatality Rates

If we assume that control plots adequately represent background mortality that could be expected if the CVSR Project did not exist, then we should be able to estimate the mortality rates related to the presence of the Project as the difference between rates within the arrays and rates in the control plots within Conservation Lands. Any such evaluation requires that fatality rates between array areas and Conservation Lands be evaluated and applied on the same spatial and temporal scale. Control plots were designed specifically for this purpose by making them equivalent to the size of a typical tracker unit. This allowed us to calculate a per-tracker unit fatality rate for array areas, and a per-control plot fatality rate for Conservation Lands that represents the same spatial scale. Because the focus of the fatality survey effort was to develop an overall fatality rate for the Project with a certain level of precision, more effort was spent surveying tracker units within arrays than control plots within Conservation Lands. Approximately one control plot was established for every eight tracker units surveyed within the arrays. The larger sample size of tracker-unit sized plots within the arrays versus those in Conservation Lands resulted in higher precision in estimating fatality rates in the array areas as compared to Conservation Lands.

To estimate the fatality rate related to the CVSR Project, we used bootstrap methods and the results from the Fatality Estimator to estimate the mean and 90% confidence intervals of the difference between per-tracker fatality rates within array areas and per-control plot fatality rates within Conservation Lands.. In an attempt to account for differences in sample sizes between array areas and Conservation Lands, we subsampled array areas at a sample size equal to the number of control plots. By applying this method to the results from the Fatality Estimator, we adjusted the individual fatalities to account for imperfect detection due to searcher efficiency and carcass persistence rates.

Definitions:

N_C = Total number of control plots within Conservation Lands that were surveyed for the entire study period,
N_T = Total number of tracker units surveyed within array areas during the study period,
n_c = number of randomly sampled control plots,
n_t = number of randomly sampled tracker units,
F_C = Total estimated fatalities across all n_c over the study period,
F_T = Total estimated fatalities across all n_t over the study period,
F_{con} = estimated background fatality rate based upon control plots over the study period,
F_{trac} = estimated per-tracker unit fatality rate within arrays over the study period,
$F_{b.adj}$ = estimated per-tracker unit fatality rate that is adjusted by subtracting background fatality rates, and
m = the number of bootstrap iterations.
Note that $n_c = n_t = N_C$.

The bootstrap process proceeded as follows:

1. Randomly sample n_c control plots, with replacement, from the N_C control plots at the study site. Note that because we are sampling with replacement, an individual control plot may be represented more than once.
2. Based on the new random sample of n_c control plots, estimate the total fatality rate for control plots, F_C, using the Fatality Estimator .
3. Estimate the per-control plot fatality rate, which equates in spatial scale to the per-tracker unit fatality rate: $F_{con} = F_C / N_C$.
4. Randomly sample n_t tracker units, with replacement, from the N_T tracker units in the study area.
5. Based on the new random sample of n_t tracker units, estimate the total fatality rate for tracker units sampled, F_T, using the Fatality Estimator. Note that we are estimating total fatalities for N_C number of tracker units, and not for the entire facility or the N_T number of tracker units surveyed.
6. Estimate the per-tracker fatality rate: $F_{trac} = F_T / N_C$.
7. Calculate the adjusted, per-tracker fatality rate as the difference between the per-control plot fatality rates and the per-tracker fatality rates from 3 and 6, above ($F_{b.adj} = F_{trac} - F_{con}$).
8. Do this m number of times, yielding m values of $F_{b.adj}$. ($m = 2000$).
9. Estimate the adjusted, per-tracker fatality rate as the mean of the m values of $F_{b.adj}$, and the 90% confidence intervals as the 0.05 and 0.95 quantiles of those values.

Sampling only N_C trackers from the much larger N_T trackers that were actually surveyed at the site is intended to simulate a balanced paired design, as if we had sampled an equal amount of area in the arrays and within the onsite Conservation Lands. If we had not done so, our degree of confidence in the mean per-tracker unit fatality rate for array areas would be much higher than the mean control plot fatality rate in Conservation Lands due to the relatively low sample size of control plots, which could result in biased estimates. It should be noted that when we applied this analysis to results from the Fatality Estimator, we did not account for uncertainty in searcher efficiency and carcass persistence sub-models; and therefore, we invoke an assumption that the parameters of those models are known without error. Consequently, the results of this bootstrap analysis only represent error associated with the random and incomplete sampling of tracker units within arrays and control plots within onsite Conservation Lands (i.e., sampling error).

Section 3.0 Results

3.1 Weekly Searches

A total of 360 avian fatalities were found during weekly fatality searches of Project elements and control plots between 16 August 2013 and 17 November 2014 (Figures 4–11; Appendix C). An additional four clearance fatalities were also found during weekly searches. However, because time since death cannot be reliably established, we do not include clearance fatalities in any further discussion in this section. No bat fatalities were found during the current reporting period.

Of the 360 fatalities found during weekly searches, the majority (65%) was found in arrays, and 307 (85%) fatalities were year-round avian residents (Table 3).

Table 3. Number of Fatalities Found at Each Project Element, by Residency Status

	Migrant	Resident	Winter Resident	Unknown[1]	Total
Arrays	5	217	9	3	234
Control plots	1	16	0	0	17
Evaporation Pond	0	4	0	0	4
Fences	0	11	1	2	14
Gen-tie Line	14	38	11	2	65
MVOH Line	0	21	2	3	26
Total	20	307	23	10	360

Note:
[1] Unidentified species among the fatalities were grouped as having Unknown residency status.

To assess the effect of season on fatalities, we excluded fatalities from Arrays 1 and 2 that were detected outside the reduced 20% search areas before January 2014. Additionally, one fatality found in a control plot was excluded; this control plot was removed in January 2014 to coincide with the reduced search effort in Arrays 1 and 2. Inclusion of these data would inflate seasonal numbers for these areas, because a greater search effort occurred before January. However, we excluded these data only for the analysis presented here, in Section 3.1. All subsequent sections include all available data from this reporting period.

There was seasonal variation in fatalities across the different Project elements (Table 4; Figures 12-16). The arrays and Gen-tie Line showed the most variation in the numbers of fatalities found across seasons (Figures 12 and 15). The largest number of fatalities in the arrays occurred in winter, accounting for 48.3% of all array fatalities (Table 4). There was a steady decline in fatalities in the arrays after winter, and this decline carried into fall 2014. Also, array fatalities were lower in fall 2014 compared with fall 2013. The largest number of fatalities along the Gen-tie Line occurred in fall 2013, accounting for 39.06% of all Gen-tie Line fatalities. Gen-tie Line fatalities declined after fall 2013 but remained fairly constant. Like array fatalities, Gen-tie Line fatalities in fall 2014 were lower than in fall 2013. There was also a slight spike in fatalities in the winter along the MVOH Line, but overall numbers for this Project element were too low to establish trends. Likewise, fatalities found along the fences and at the Evaporation Pond and control plots were too few to establish trends.

3.2 Repeat Searches

This section presents the results of all repeat searches, which (in the final year of monitoring) were conducted from 16 August through 31 December 2013. For reasons discussed in Section 2.1.2, we did not calculate fatality estimates based on the results of the 5-day repeat searches or the 1-day repeat searches in 5-day search areas for this report. However, because the 1-day repeat searches of weekly search areas affected the search interval for weekly searches and occurred in overlapping areas, these results were included in total fatality estimates (consistent with the first annual report [HTH 2014a]).

In total, 54 fatalities were detected during repeat searches across all Project elements and control plots. Eighteen of these fatalities were clearance fatalities and are not discussed further, for reasons described earlier. Therefore, the effective sample size for repeat searches was 36 fatalities. Combining the results of all repeat searches, the largest percentage (83.3%) of fatalities was found in the arrays. Details of fatalities found during each type of repeat search are presented below.

3.2.1 5-Day Repeat Searches

Nineteen fatalities were found during 5-day repeat searches between 16 August and 31 December 2013. An additional 18 clearance fatalities were found but not used in any analyses. One of these fatalities was found directly under the MVOH Line, suggesting collision as the cause of death (>50% certainty, or Probable). The cause of death for the remainder of fatalities was unknown.

3.2.2 1-Day Repeat Searches of Weekly Search Areas

Fifteen fatalities were found during 1-day repeat searches of weekly search areas during this annual reporting period. Two feather spots were found directly under the Gen-tie Line and were considered to have >50% probability of death by collision (Probable). The carcass of a mourning dove was found in Array 2. This carcass had bruising on its right foot and signs of trauma to its right shoulder and chest, suggesting that collision was a Valid (>90% certainty) cause of death. The cause of death for the remainder of fatalities was unknown.

3.2.3 1-Day Repeat Searches of 5-Day Repeat Search Areas

Two fatalities were found during 1-day repeat searches of 5-day repeat search areas between 16 August and 31 December 2013. One was the feather spot of a mourning dove, found along the fence in Array 8 on 18 October. The second was the feather spot of a common raven (*Corvus corax*), found in Array 9 on 8 November. The causes of death could not be discerned for these fatalities.

3.3 Incidental Fatalities

Thirty-five incidental fatalities were found between 16 August 2013 and 17 November 2014. This number includes two fatalities that were found in onsite Conservation Lands. Of the total number of fatalities found incidentally, 46.8% were found in arrays. Only one fatality was found and reported by CVSR Project staff.

Two ravens were found in separate events and both were suspected to have died from electrocution. A pied-billed grebe (*Podilymbus podiceps*) was observed being consumed by a coyote (*Canis latrans*), but because grebes are obligate waterbirds, collision was assigned as the cause of death. A mourning dove was also assumed to have died from collision after a smudge mark was discovered on an otherwise clean panel above a feather spot.

3.4 Trends in Total Fatalities

The subsections that follow present combined counts of fatalities found during weekly searches, repeat searches, and incidental detections. The purpose of combining these counts is to use all available data to help illustrate possible trends associated with Project elements and species.

Overall, 453 fatalities were found during weekly and repeat searches of Project elements, and incidentally. Twenty two of these fatalities were clearance fatalities, and 2 of the incidentally discovered fatalities were found on onsite Conservation Lands. In this section, we do not include any further discussion of clearance fatalities or fatalities found on Conservation Lands outside of control plots. Therefore, the effective sample size discussed for all Project elements in this section is 429 fatalities. The majority of these fatalities were found in arrays (Figure 17).

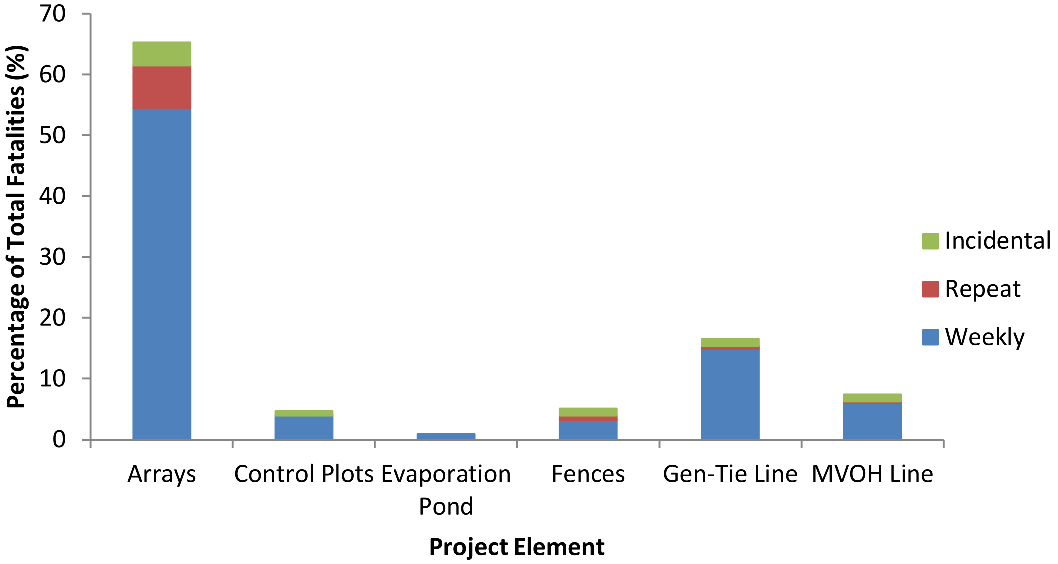

Figure 17. Percentage of Total Fatalities Found during Weekly Searches, Repeat Searches, and Incidentally at All Project Elements (N=429)

Note: Incidental fatalities found in onsite Conservation Lands, and clearance fatalities, are not included.

3.4.1 Cause of Death

Of the 429 fatalities found in Project elements and control plots, the cause of death for the majority (80.9%) could not be reliably discerned. Seventy-three (17.0%) were believed to have died as a result of a collision (50 on the Gen-tie Line, 15 on the MVOH Line, 7 with solar panels, and 1 with a perimeter fence). Two fatalities were believed to be electrocuted (0.5%). Six (1.4%) were believed to have been killed by predators, and one (0.2%) was believed to have died from disease.

Both electrocution deaths occurred along the MVOH Line (Figure 18). Although none of the fatalities found in control plots had a known cause of death, >45% of the fatalities found along the Gen-tie Line and MVOH Line were believed to be the result of collision. This determination was based primarily on the location of fatalities directly or nearly directly under the lines. Only eight fatalities found in arrays were linked to known causes of death (seven panel collisions and one predation event), and the remaining 97.1% of fatalities found in arrays were assigned an unknown cause of death.

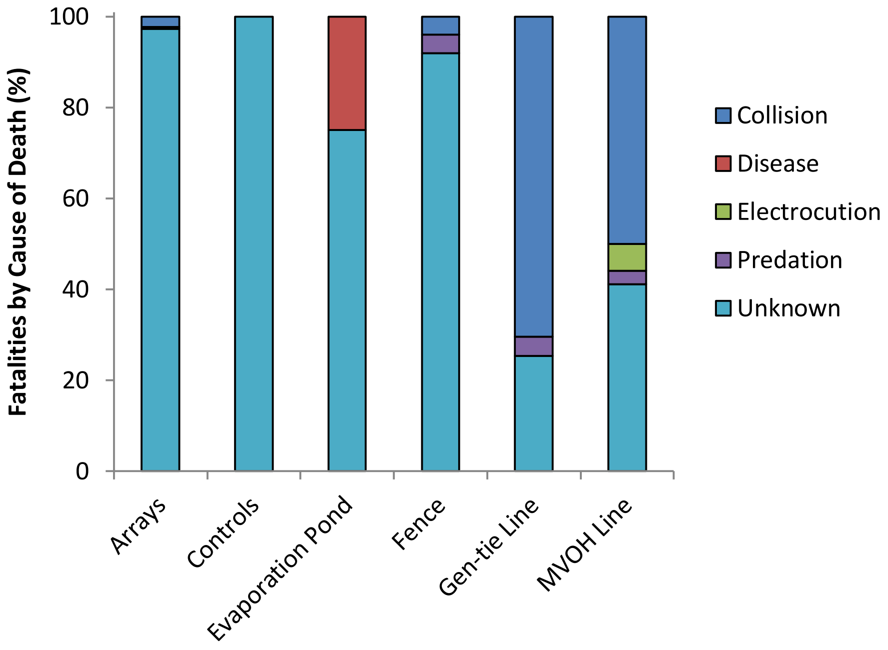

Figure 18. Cause of Death by Project Element

3.4.2 Fatalities by Species

In total, we found fatalities from 36 known avian species and 5 fatalities that did not provide enough information to assign them to a species (Table 5). With the exception of two American coots (*Fulica americana*) found in Arrays 4 and 5, and one pied-billed grebe found in Array 7, all known fatalities were terrestrial avian species.

Mourning doves accounted for the greatest percentage of fatalities (38.9%) found, with horned larks and house finches (*Carpodacus mexicanus*) composing the second (13.5%) and third (13.1%) most frequently observed fatalities, respectively. Fatalities from three special-status species, burrowing owl (*Athene cunicularia*), loggerhead shrike (*Lanius ludovicianus*), and yellow warblers (*Setophaga petechial*) were detected during weekly searches, but combined, these fatalities accounted for only about 3% of the total number of fatalities found during weekly searches.

Table 5. Number of Fatalities Found, by Species

Species	Scientific Name	AOU Code[4]	Fatalities Recorded
Mourning dove[2]	*Zenaida macroura*	MODO	167
Horned lark[1]	*Eremophila alpestris*	HOLA	58
House finch[1]	*Haemorhous mexicanus*	HOFI	56
Western meadowlark[1]	*Sturnella neglecta*	WEME	30

Wilson's warbler[1]	*Wilsonia pusilla*	WIWA	1
Total			**429**

Notes:

[1] Denotes species modeled as small birds in the Fatality Estimator.

[2] Denotes species modeled as large birds in the Fatality Estimator.

[3] These unidentifiable species were examined and determined to be large or small birds for the purposes of the Fatality Estimator on a case-by-case basis.

[4] Codes designated by the American Ornithologists' Union (AOU) Check-list of North American Birds (AOU 2015). Codes for unknown species are not designated by the AOU. For purposes of this report, unidentifiable large birds, small birds, raptors, or passerines are designated as UNKN. Unidentifiable warblers are designated as UNWA.

3.4.3 Fatalities by Residency Group

When comparing migrants (transient species traveling between summer breeding grounds and wintering grounds), residents (species living in the region year-round), and winter residents (species present in the region only in the winter), across all Project elements, residents accounted for the highest proportion of fatalities in arrays (70.46%), compared with all other Project elements (Table 6). Migrants and winter residents accounted for the highest number of fatalities along the Gen-tie Line (63.64% and 51.85%, respectively), compared with all other Project elements.

Table 6. Percent of Residency Group Fatalities across Project Elements (N=429)

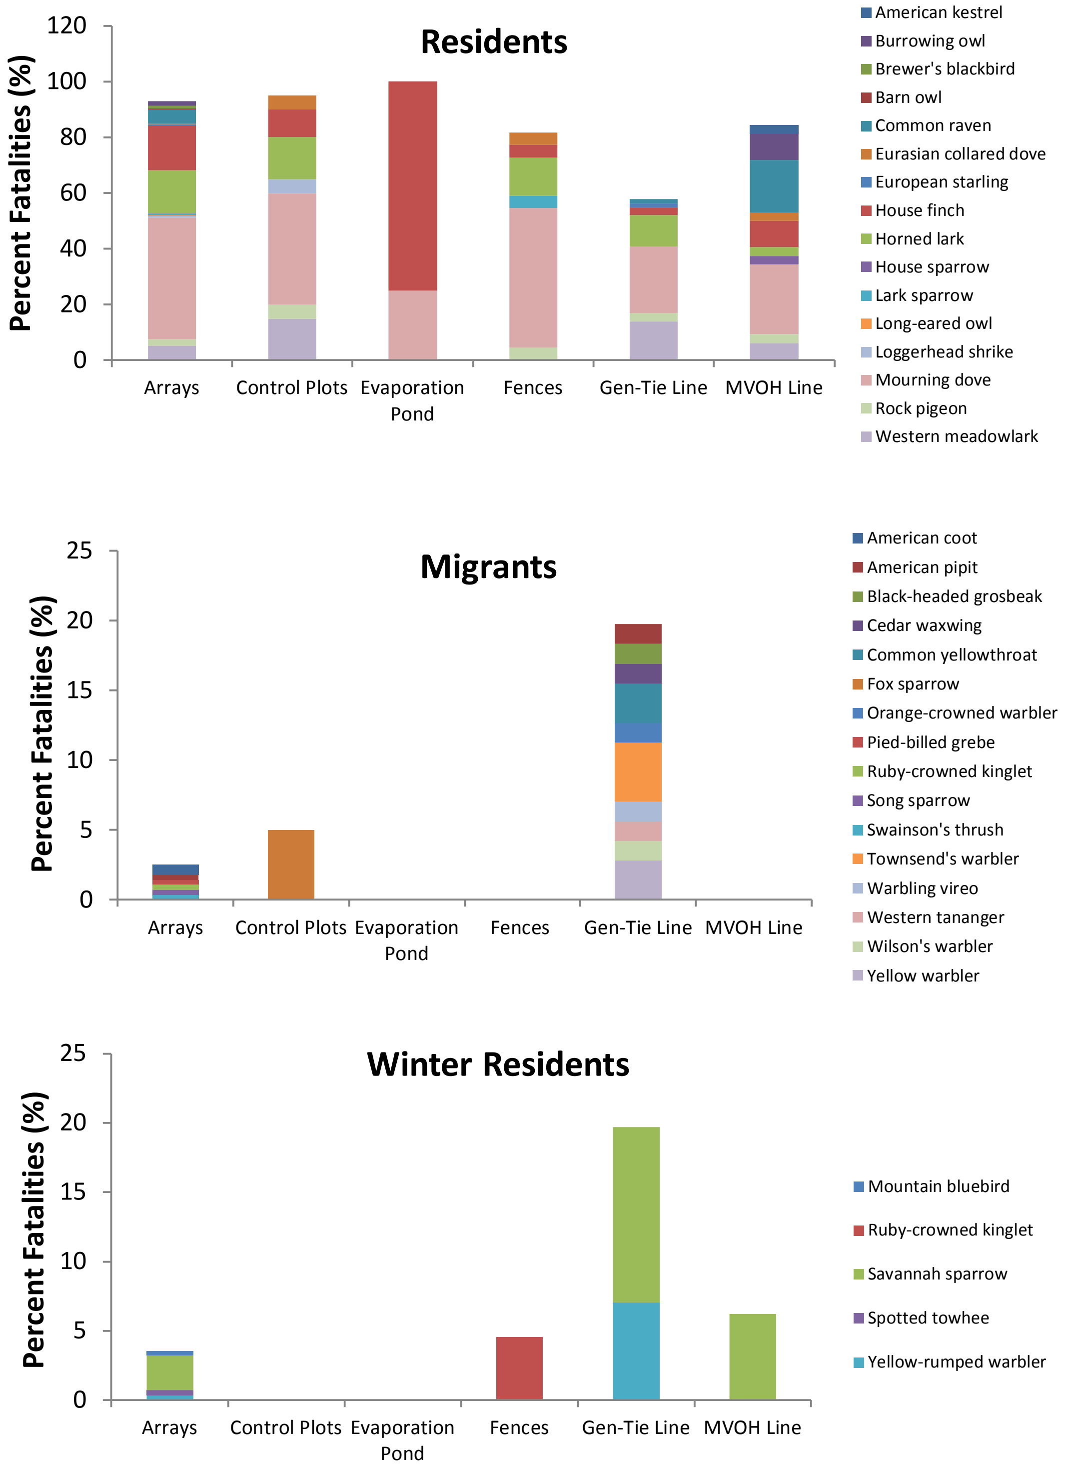
	Percent (%) of Fatalities			
Project Element	**Migrant**	**Resident**	**Winter Resident**	**Unknown**
Arrays	31.82	70.46	37.04	27.27
Control plots	4.55	5.15	0.00	0.00
Evaporation Pond	0.00	1.08	0.00	0.00
Fences	0.00	4.88	3.70	27.27
Gen-Tie Line	63.64	11.11	51.85	18.18
MVOH Line	0.00	7.32	7.41	27.27
Residency Group Total	100	100	100	100

Within each Project element, avian resident fatalities accounted for the highest percentage of fatalities (Table 7, Figure 19). Migrant and winter resident fatalities accounted for the second highest percentage of fatalities (19.72% and 19.72%), but only with the Gen-tie Line.

Table 7. Percent of Residency Group Fatalities within Project Elements (N=429)

	Percent (%) of Fatalities in Each Project Element				
Project Element	**Migrant**	**Resident**	**Winter Resident**	**Unknown**	**Total Percent Fatalities**
Arrays	2.50	92.86	3.57	1.07	100
Control plots	5.00	95.00	0.00	0.00	100
Evaporation Pond	0.00	100.00	0.00	0.00	100
Fences	0.00	81.82	4.55	13.64	100
Gen-tie Line	19.72	57.75	19.72	2.82	100
MVOH Line	0.00	84.38	6.25	9.38	100

Within each Project element, the highest species richness of fatalities was found in the arrays and along the Gen-tie Line, but the overall species composition of fatalities for these Project elements differed. The MVOH line had the third highest species richness of fatalities. In contrast, no migratory species fatalities were found along the MVOH line. The lowest species richness of fatalities was found in control plots, fences and the Evaporation Pond.



Notes: Residency status is based on knowledge of species typically found on the Project site at different times of the year. Unknown species (N=11) are not included in this figure.

Figure 19. Fatalities, by Species and Residency Group, as Percentages of the Total Fatalities in Each Project Element (N=418)

3.4.4 Gen-tie Line Trends by Elevation

Both overhead lines (the Gen-tie and the MVOH Lines) had a high percentage of fatalities with known causes of death. However, the seasonal graphs of the Gen-tie Line monitoring results demonstrate peaks that could be associated with migratory activity, whereas the MVOH Line data did not. The Gen-tie Line is unique among the other Project elements in several ways: it is the only Project element that has a variety of elevations along its length, it crosses over a tamarisk wetland in the area north of State Route 58, and the powerlines are higher above the ground than those associated with the MVOH Line.

To help determine what factor had the largest effect on the differences in fatality rates and species richness of fatalities found along the two lines, we assessed the numbers of fatalities along the Gen-tie Line by elevation. Although elevation consistently increases as the tower numbers increase from the substation (Tower 1) to the Caliente switching station (Tower 23), the number of fatalities found between towers does not indicate a pattern (Figure 20). Similarly, the number of species found at different areas along the Gen-tie Line did not increase with elevation, and did not cluster around the tamarisk wetland located between Gen-tie Line towers 17 and 18 (Figure 21).

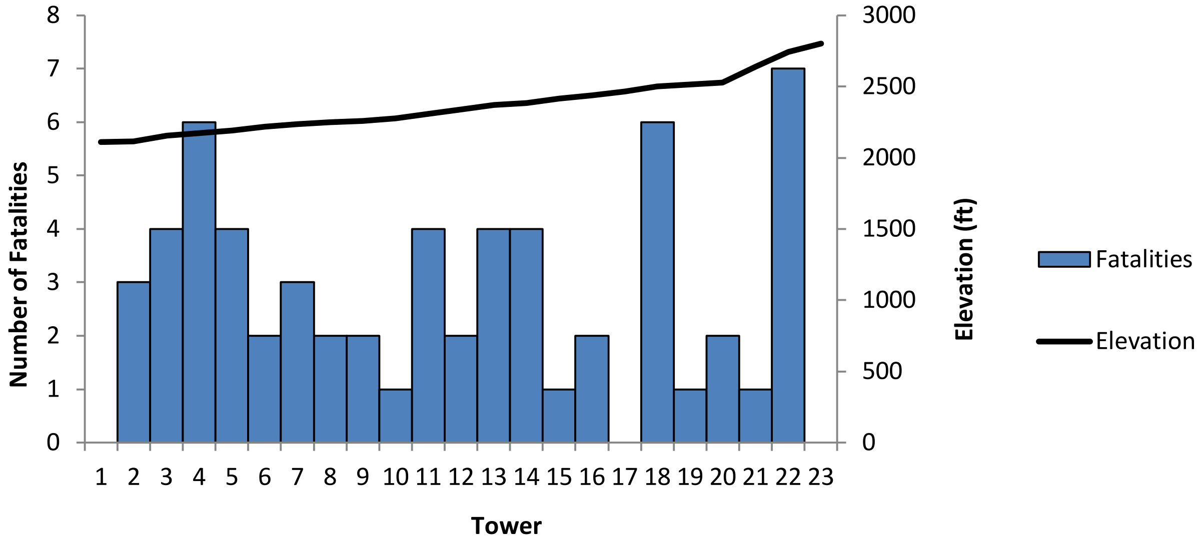


Figure 20. Number of Fatalities along the Gen-tie Line, by Elevation and Tower Number

Note: Fatalities are grouped from tower to tower (e.g., all fatalities found between the substation and Tower 1 are graphed under Tower 1).

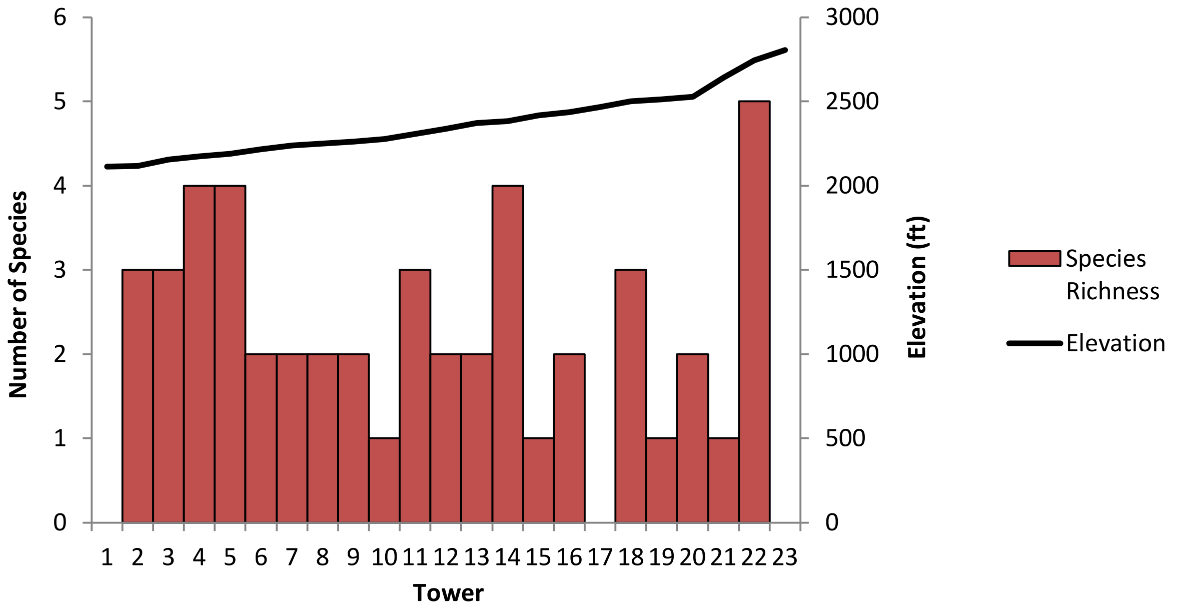

Figure 21. Species Richness of Fatalities Found along the Gen-tie Line, by Elevation and Tower Number

Note: Fatalities are grouped from tower to tower (e.g., all fatalities found between the substation and Tower 1 are graphed under Tower 1. The tamarisk wetland is located between Towers 17 and 18).

3.5 Fatality Estimates

3.5.1 Carcass-persistence Rates

3.5.1.1 Overall Project Site Persistence Rates

Between 15 October 2012 and 11 March 2014, we conducted carcass-persistence trials using 206 fatality plants. Eleven fatality plants were excluded because full persistence data were not collected (i.e., carcasses were collected by staff after the initial scavenging event). One-hundred and five carcasses were placed after the first annual reporting period, but because the results of both years were used to inform persistence times in the Fatality Estimator, the results of all trials are presented here.

From our 30 feather spot persistence trials, we calculated that feather spots persisted an average of 18 days on bare ground, 35 days in low grass (≤25 cm), and 45 days in medium or high grass (>25 cm). We applied these values as adjustment factors for all feather spots that persisted after scavenging, and these are the values we report below, unless otherwise noted. Feather spots that were left on low grass with <50% cover in a 1-m^2 area were assigned the same adjustment factor as those on bare ground.

3.5.1.2 Persistence Rates by Explanatory Variables

Observed scavenger species included common ravens, which scavenged 46.2% of all planted fatalities; San Joaquin kit foxes (*Vulpes macrotis mutica)*, which scavenged 22.1% of all planted fatalities; coyotes, which scavenged 5.6% of all planted fatalities; and one of each of the following: a turkey vulture (*Cathartes aura*), a prairie falcon

(*Falco mexicanus*), and a red-tailed hawk (*Buteo jamaicensis*) (Figure 22). Two planted carcasses, a great horned owl (*Bubo virginianus*) and a red-tailed hawk, remained mostly intact for the full 6-week monitoring period, so no final scavenger species was assigned to these carcasses. Unknown scavengers accounted for 23.6% of all scavenging events.

After 7 days, only 10.8% of all small carcasses remained unscavenged. However, 25.0% of all small carcasses and resultant feather spots remained in place (Figure 23). This effect was even more dramatic for large carcasses: whereas only 25.3% of all carcasses remained after a week, more than half (65.7%) of all large carcasses either remained in place or left feather spots behind.

Figure 22. Scavenger Species Documented in Carcass-persistence Trials

Notes: Clockwise from top left, recorded scavenger species were as follows: common raven, San Joaquin kit fox, turkey vulture, red-tailed hawk, prairie falcon, and a coyote.

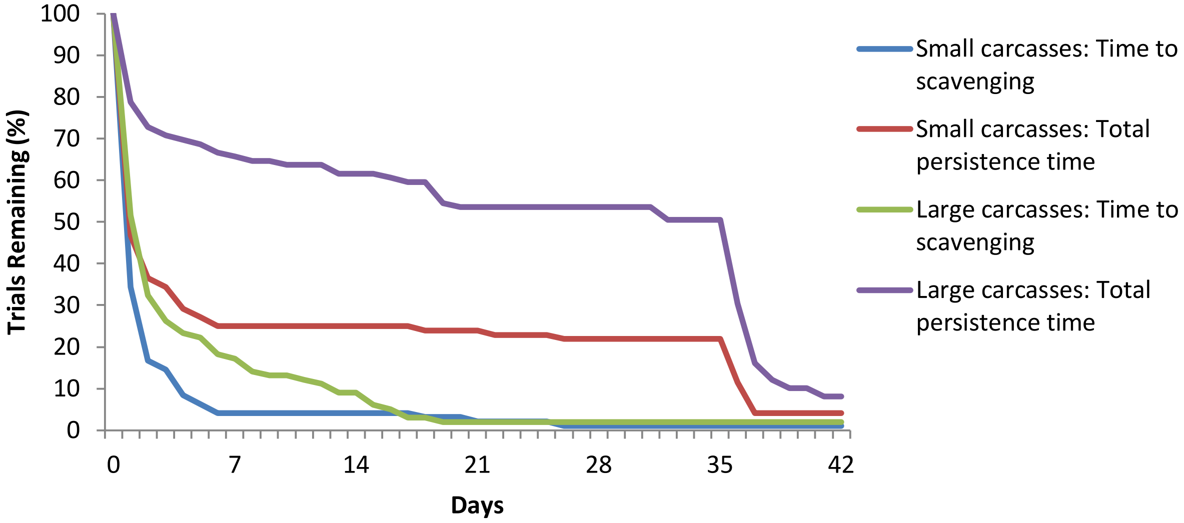

Figure 23. Percent of All Carcasses and Resultant Feather Spots Remaining Over Time (N=195)

Time to scavenging was longest for both large and small carcasses in the winter. Assuming conservatively that carcasses would not persist past the 6-week trial period, mean carcass persistence over the entire year was 9.3 days for small carcasses and 22.2 days for large carcasses. Total persistence times did not exhibit a clear seasonal pattern, but clearly varied by carcass size (Table 8).

Table 8. Average Time to Scavenging and Average Total Persistence, by Size and Season

Season	Carcass Size	N	Average Time to Scavenging (days)	Average Total Persistence (days)
Fall	Small	29	1.52	11.91
	Large	28	2.77	17.80
Winter	Small	29	3.56	9.87
	Large	30	5.16	17.27
Spring	Small	22	1.62	4.30
	Large	28	4.03	30.51
Summer	Small	16	1.08	12.02
	Large	13	2.53	27.34

3.5.1.3 Model Selection for Carcass-persistence Decay Curve

Based on the carcass-persistence data, we compared 16 possible models. The model with the lowest AICc had a lognormal distribution and controlled for carcass size but not season (Table 9). Because the ΔAICc is >2 between this model and the next ranked model, this model alone has substantial support, and we used this model in the fatality estimates.

Table 9. AICc Values for Each of 16 Models of Carcass Persistence

Distribution	Model Formula	AICc	Shape
Exponential	Null	1012.0	1.0
Exponential	Season	1010.7	1.0
Exponential	Size	946.6	1.0
Exponential	Season + Size	949.4	1.0
Loglogistic	Null	680.1	2.41
Loglogistic	Season	684.1	2.39
Loglogistic	Size	637.2	2.06
Loglogistic	Season + Size	639.8	2.04
Lognormal	Null	671.7	3.92
Lognormal	Season	675.7	3.89
Lognormal	**Size**	**631.8**	**3.45**
Lognormal	Season + Size	634.4	3.41
Weibull	Null	699.3	3.21
Weibull	Season	702.3	3.19
Weibull	Size	659.2	2.96
Weibull	Season + Size	663.1	2.95

Notes: AICc = Akaike's Information Criterion, adjusted for sample size. Lognormal model in **bold** is best supported. "Null" indicates models with no explanatory variables.

3.5.2 Searcher-efficiency Rates

Between 5 September 2012 and 31 July 2014, we conducted 434 searcher-efficiency trials in all operational Project elements throughout the site. Three trial specimens (two large carcasses and one small carcass) were removed by scavengers and not used in analysis. Therefore, we used a total of 431 fatality trial specimens: 113 small and 98 large feather spots, and 113 small and 107 large carcasses. Fatality plants were placed in areas with various combinations of vegetation height and percent cover.

Overall searcher efficiency was 50.8% (Table 10). When accounting for size and visibility class, each on their own, searchers were most effective at detecting large carcasses, large feather spots, and fatality plants placed in the Easy visibility class. When accounting for size and visibility class together, searcher efficiency for large carcasses and large feather spots in the Easy visibility class was 80% and 77.1%, respectively. Searcher efficiency was slightly lower for large carcasses in the Moderate visibility class, at 66.7%, and was 50.9% for small carcasses in the Easy visibility class. At 25.5%, searchers were least effective at finding small feather spots in the Moderate visibility class.

Table 10. Results from Searcher-efficiency Trials, September 2012 through July 2014

Category	Detection Rate (%)	N
Overall	50.8	431
Size Class		
Large carcass	72.9	107
Small carcass	41.6	113
Large feather spot	65.3	98
Small feather spot	26.5	113
Visibility Class		
Easy visibility	57.3	211
Moderate visibility	44.5	220
Size Class and Visibility Class		
Large carcass, Easy visibility	80.0	50
Large carcass, Moderate visibility	66.7	57
Small carcass, Easy visibility	50.9	55
Small carcass, Moderate visibility	32.8	58
Large feather spot, Easy visibility	77.1	48
Large feather spot, Moderate visibility	54.0	50
Small feather spot, Easy visibility	27.6	58
Small feather spot, Moderate visibility	25.5	55

3.5.2.1 Model Selection

Based on the searcher-efficiency trial data, we compared four possible models. The model with the lowest AICc controlled for both visibility class and size class (Table 11). Because the ΔAICc is >2 between this model and the next ranked model, this model alone has substantial support, and we used this model in the fatality estimates.

Table 11. AICc Ranking of Searcher-efficiency Models

Model	AICc
Null	599.39
Visibility	594.33
Size Class	543.89
Size Class + Visibility	**536.23**

Notes: AICc = Akaike's Information Criterion, adjusted for sample size.
Model in **bold** is best supported.

3.5.3 Fatality Estimates for Known Causes

After determining the proper model structure for both searcher-efficiency and carcass-persistence trials, we ran a series of fatality estimates. We report fatality estimates only for areas and categories in which more than five fatality detections occurred, because using the Fatality Estimator with five or fewer detections produces highly biased values due to the small sample size.

Fatality estimates were calculated separately for each Project element, with the exception of the Evaporation Pond, where a low sample size precluded running a fatality estimate. Estimates are first provided for fatalities where the cause of death was determined based on direct evidence of collision or electrocution. Following these estimates, we provide estimates for fatalities where the cause of death could not be determined or was natural (i.e., cause of death was disease or predation) (Section 3.5.4).

3.5.3.1 Total Fatality Estimates for Known Causes

Of the 53 fatalities for which the cause of death could be determined, 40 were included in the fatality estimate models (Table 12). Two from the arrays were excluded from the model but then added, unadjusted, to the estimator output, to produce the total fatality estimate for known causes. Eleven fatalities with evidence of electrocution or collision were not included in the fatality estimates: four were excluded because they were found incidentally, five were excluded because they were older than the search interval, and two were excluded because they were found in Array 1 and 2 outside of the 20% search areas established in January 2014.

Table 12. Number of Detections Based on Known Causes in Each Project Element, and Number Included in Fatality Estimates, 7 November 2013 to 6 November 2014

	Fatalities Detected		
Project Element	**Number Included**	**Number Excluded**	**Total Found**
Arrays	0	6[1,2]	6
Control plots	0	0	0
Evaporation Pond	0	0	0
Fences	0	0	0
Gen-tie Line	29	5[3]	34
MVOH Line	11	2[4]	13
Total	**40**	**13**	**53**

Notes:
[1] Two fatalities were excluded because they were incidentals and two fatalities were excluded because they were found outside of the 20% areas for Array 1 and 2 prior to January 2014.
[2] No estimate was provided for this element because of the low sample size; the remaining two fatalities (see Note 1) were added unadjusted to the overall estimator output.
[3] Five fatalities were excluded because they were older than the search interval.
[4] Two electrocuted fatalities were excluded because they were found incidentally.

During the period of 7 November 2013 to 6 November 2014, an estimated 126 birds died from electrocution- or collision-related causes (90% confidence interval: 106–155) at the Project site (Table 13).

Table 13. Estimates of Total Fatalities with Known Causes, 7 November 2013 to 6 November 2014

Project Element	Number of Fatalities Included in Model	Estimate of Fatalities (with Lower and Upper 90% Confidence Limits)
Arrays	0	n/a[1]
Control plots	0	n/a[2]
Evaporation Pond	0	n/a[2]
Fences	0	n/a[2]
Gen-tie Line	29	99 (83, 123)
MVOH Line	11	25 (21, 30)
Total for Project site[1]	**40**	**126 (106, 155)[1]**

Notes:
[1] The two fatalities in the arrays were added unadjusted to the total fatality estimate for the site.
[2] n/a = not applicable; no fatalities caused by electrocution or collision were found in these elements.

3.5.3.2 Fatality Estimates by Project Element

No fatalities that were found in control plots, at the Evaporation Pond, or along fences provided direct evidence of electrocution or collision, so we do not provide a fatality estimate for known causes based on fatalities found in these project elements. Likewise, due to the low number of fatalities found with known causes of death in the array areas, we do not provide a fatality estimate for the array areas.

The overhead powerlines were the only areas for which we estimated the number of fatalities caused by collision or electrocution. Ninety-nine fatalities were estimated to have occurred as a result of collision along the Gen-tie Line (90% confidence interval: 83–123; Table 14). Seasonal estimates were not made for the Gen-tie Line by cause of death because very few fatalities were found in the winter (N=4).

Table 14. Fatality Estimates for the Gen-tie Line, by Cause of Death (Electrocution or Collision), and Fatality Class, 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimated Total Number of Fatalities[1]	Lower and Upper 90% Confidence Limits
Cause of Death			
Electrocution	0	0	n/a[1,2]
Collision	29	99	83, 123
Fatality Class			
Large	7	19	15, 24
Small	22	81	65, 104

Notes:

[1] The bootstrap methods used to produce the fatality estimate produce estimates for the entire dataset that differ slightly from the sum of estimates for constituent subgroups of the data.
[2] n/a= not applicable; no electrocution-related fatalities were found in the Gen-tie Line area.

An estimated 25 fatalities occurred along the MVOH Line as a result of collision between 7 November 2013 and 6 November 2014 (90% confidence interval: 21–30; Table 15). Seasonal estimates for the MVOH Line were not calculated due to low sample sizes in the summer, fall, and winter (N=1, N=2, and N=2, respectively). Estimates by size also were not calculated, because of a low sample size for small birds (N=2).

Table 15. Fatality Estimates for the MVOH Line by Cause of Death (Electrocution or Collision), 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimated Total Number of Fatalities	Lower and Upper 90% Confidence Limits
Cause of Death			
Electrocution	0[1]	0	n/a[2]
Collision	11	25	21, 30

Notes:
[1] Two electrocution-related fatalities were excluded from the model because they were found incidentally.
[2] n/a = not applicable; no electrocution-related fatalities found along the MVOH Line were included in the model.

3.5.4 Fatality Estimates for Unknown and Natural Causes of Death

For the purposes of these estimates, fatalities with suspected natural causes of death (i.e., predation or disease) are included in this section, along with fatalities for which cause of death could not be determined. We did not calculate separate estimates for predation or disease; instead, these fatalities are grouped in with the total estimates for fatalities with unknown causes of death. Of the 251 fatalities for which the cause of death was natural or could not be determined, 186 were included in the fatality estimate models (Table 16). Of the excluded fatalities, four each from the Evaporation Pond and Gen-tie Line were later added unadjusted to the estimator output, to produce the total fatality estimate for unknown causes. There were 65 fatalities with an unknown or natural cause of death that were not included in the fatality estimates; 20 were excluded because they were found incidentally, 9 were excluded because they were older than the search interval, 1 was excluded because it was found in a control plot that was removed in January 2014 when the search areas for Arrays 1 and 2 were reduced to 20%, and 27 were excluded because they were found in Array 1 and 2 outside of the 20% search areas established in January 2014.

Table 16. Number of Unknown-cause and Natural Fatalities Detected in Each Project Element, and Number Included in Fatality Estimates, 7 November 2013 to 6 November 2014

	Fatalities Detected		
Project Element	**Number Included**	**Number Excluded**	**Total Found**
Arrays	150	45[1]	195
Control plots	14	4[2]	18
Evaporation Pond	0	4[3]	4
Fences	11	4[4]	15
Gen-tie Line	0	4[5]	4
MVOH Line	11	4[6]	15
Total	**186**	**65**	**251**

Notes:

[1] Seven fatalities were excluded because they were older than the search period, 11 fatalities were excluded because they were found incidentally, and 27 were excluded because they were found outside of the 20% search areas for Arrays 1 and 2 prior to January 2014.

[2] Three fatalities were excluded because they were found incidentally, and one fatality was excluded because it was in a control plot that was removed when the search areas for Array 1 and 2 were reduced to 20%.

[3] No estimate was provided for these elements because of the low sample size; however, these detections were later added unadjusted to the estimator output.

[4] Three fatalities were excluded because they were found incidentally, and one fatality was excluded because it was older than the search interval.

[5] No estimate was provided for these elements because of the low sample size; however, these detections were later added unadjusted to the estimator output.

[6] Three fatalities were excluded because they were found incidentally, and one fatality was excluded because it was older than the search interval.

During the period of 7 November 2013 to 6 November 2014, an estimated 2597 birds died from unknown causes (90% confidence interval: 2116-3334) at the Project site (Table 17).

Table 17. Estimates of Unknown-cause and Natural Fatalities, 7 November 2013 to 6 November 2014

Project Element	Number of Fatalities Included in Model	Estimate of Fatalities (with Lower and Upper 90% Confidence Limits)
Arrays	150	2314 (1890, 2965)
Control plots	14	52 (31, 81)
Evaporation Pond	0[1]	n/a[2]
Fences	11	185 (155, 230)
Gen-tie Line	0[1]	n/a[2]
MVOH Line	11	39 (32, 50)
Total for Project site[1]	**186**	**2598 (2116, 3334)**[1]

Notes:

[1] In total, eight fatalities with unknown or natural causes of death were found in the Evaporation Pond area and the Gen-tie Line area. These were added, unadjusted, to the total fatality estimate for the site.

[2] n/a = not applicable; there were fewer than five fatalities in this group. However, the unadjusted numbers were added to the fatality estimates and confidence intervals.

3.5.4.1 Fatality Estimates by Project Element

Because few fatalities were found in the Evaporation Pond and few with unknown causes of death were found along the Gen-tie Line, we do not provide fatality estimates for these fatalities here.

An estimated 2314 fatalities (90% confidence interval: 1890–2965) occurred in the arrays from unknown or natural causes in the year 7 November 2013 to 6 November 2014 (Table 18). The estimated number of fatalities per tracker in the arrays was 2.24 (90% confidence interval: 1.83–2.87), whereas in the control plots it was 1.72 (90% confidence interval: 1.05–2.68; Table 19).

Table 18. Fatality Estimates for the Arrays, by Cause of Death (Unknown), Fatality Class and Season, 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimate of Fatalities per Tracker[1]	Lower and Upper 90% Confidence Limits	Estimated Total Number of Fatalities[1]	Lower and Upper 90% Confidence Limits
Cause of Death					
Unknown	150	2.24	1.83, 2.87	2314	1890, 2965
Fatality Class					
Large	84	0.89	0.69, 1.17	920	712, 1209
Small	66	1.34	0.97, 1.89	1385	1002, 1953
Season					
Fall	28	0.32	0.2, 0.46	331	206, 476
Winter	85	1.24	0.94, 1.69	1281	971, 1746

Spring	27	0.47	0.27, 0.77	486	278, 796
Summer	10	0.21	0.07, 0.42	217	72, 434

Note:
[1] The bootstrap methods used to produce the fatality estimate produce estimates for the entire dataset that differ slightly from the sum of estimates for constituent subgroups of the data.

Table 19. Fatality Estimates for the Control Plots, by Cause of Death (Unknown), Fatality Class, and Season, 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimate of Fatalities per Tracker[1]	Lower and Upper 90% Confidence Limits	Estimated Total Number of Fatalities[1,2]	Lower and Upper 90% Confidence Limits
Cause of Death					
Unknown	14	1.72	1.05, 2.68	52	31, 81
Fatality Class					
Large	6	0.66	0.27, 1.23	20	8, 37
Small	8	1.06	0.33, 2.0	32	9, 60

Notes:
[1] The bootstrap methods used to produce the fatality estimate produce estimates for the entire dataset that differ slightly from the sum of estimates for constituent subgroups of the data.
[2] Estimated total is for 30 control plots.

An estimated 185 fatalities (90% confidence interval range: 155–230; Table 20) occurred along the fenceline between the dates of 7 November 2013 to 6 November 2014. An estimated 39 fatalities occurred (90% confidence interval range: 32–50) along the MVOH Line that could be attributed to unknown or natural causes (Table 21).

Table 20. Fatality Estimates for the Fences[1], by Cause of Death (Unknown) and Fatality Class, 7 November 2013 to 6 November 2014

	Number of Fatalities Included in Model	Estimated Total Number of Fatalities[2]	Lower and Upper 90% Confidence Limits
Cause of Death			
Unknown	11	185	155, 230
Fatality Class			
Large	6	85	65, 105
Small	5	105	80, 135

Notes:
[1] Estimates were made from 6411.2-m area searched during regular fatality searches and extrapolated to represent total fence area of 32,056 m.
[2] Bootstrap methods used to produce the fatality estimate produce estimates for the entire dataset that differ slightly from the sum of estimates for constituent subgroups of the data.

Table 21. Fatality Estimates for the MVOH Line, by Cause of Death (Unknown), 7 November 2013 to 6 November 2014

	Number of Detections Included in Model	Estimated Total Number of Fatalities	90% Confidence Intervals
Cause of Death			
Unknown	11	39	32, 50

3.6 Annual Background-Adjusted per-Tracker Unit Fatality Rates

The mean annual per-tracker unit fatality rate within arrays (F_{trac}), and per-control plot fatality rate within Conservation Lands (F_{con}), based on bootstrap samples were 2.24 (90% confidence interval range: 1.32 – 3.28) and 1.73 (90% confidence interval range: 0.86 – 2.74), respectively. Note that these bootstrapped estimates and confidence intervals differ slightly from those of the observed data, and are only presented here to give context for the background-adjusted estimate. The mean annual background-adjusted per-tracker unit fatality rate ($F_{b.adj}$) was 0.51 (90% confidence interval range: -0.83-1.81). The mean annual background-adjusted estimate of the number of fatalities within arrays was 526 for the period of 7 November 2013 to 6 November 2014.

Table 22. Resampled Fatality Estimates for the Control Plots, Project Plots, and Background Adjusted Fatality Estimates, 7 November 2013 to 6 November 2014. Based on 2000 iterations

Site	Mean Bootstrapped Fatality/Plot Estimate	Lower and Upper 90% Confidence Limits
Array Tracker Unit Plots	2.24	1.32, 3.28
Control Plots	1.73	0.86, 2.74
Adjusted Fatality Estimate	0.51	-0.83, 1.81[1]

[1] Negative values occur when control plot estimates exceed array tracker unit plot estimates.

Section 4.0 Discussion

This section discusses the patterns observed through monitoring, provides descriptive statistics of trends, and relates these patterns and trends to avian use of the site, and current and future research on comparable topics.

4.1 Patterns Observed in Fatality Detection Efforts

4.1.1 Avian Abundance

Fatalities in the arrays and Gen-tie Line exhibited the most seasonal variation, with definitive spikes in winter and fall 2013, respectively. Overall fatality trends in the arrays from fall 2013 through fall 2014 appear to parallel avian abundance during the same period, which was quantified during avian activity surveys conducted throughout the site and in adjacent offsite areas, as part of ABPP implementation. Avian abundance was moderately low in fall 2013, increased in winter 2013, and then steadily declined from spring to summer, with a small spike again in fall 2014 (HTH 2015). Although we cannot say definitively what the cause of death was for many of the array avian fatalities, it appears that these fatalities mirror trends in abundance; in other words, when birds are more abundant, so are array fatalities. For instance, Columbid activity (i.e., mourning doves) showed a strong seasonal pattern, with average detection rates during point counts highest in winter (HTH 2015). In contrast, although there was a spike in fatalities in fall 2013 along the Gen-tie Line, fatalities there did not parallel avian abundance seasonally in the region.

As defined by the National Drought Monitor (National Drought Mitigation Center 2014), the onset of prolonged drought translated to moderate drought conditions in the Project area by January 2013, extreme drought conditions by January 2014, and exceptional drought conditions by the end of 2014. The results of fatality monitoring may have been influenced by the three-year drought that the Project site is experiencing. The annual average precipitation at the Project site is 10.11 inches, and the site received 8.44 inches in 2011-2012, 4.01 inches in 2012-2013, and 3.43 inches in 2013-2014 (San Luis Obispo County Public Works 2014). Drought conditions were responsible for low vegetative cover in 2014 at areas within the Project site that had been revegetated, as well as undisturbed reference sites (HTH 2014b). Lower vegetative cover likely resulted in decreased food abundance, and may have contributed to declines in overall avian abundance in the Project vicinity. Therefore, overall fatality counts should be interpreted with caution, as they could differ under non-drought conditions.

4.1.2 Utility of Repeat Searches

Repeat searches were originally designed to capture higher numbers of fatalities, especially taxa like bats that are less likely to leave sign behind after scavenging, and to provide verification of the results found in weekly searches. Because it was not practical to conduct repeat searches for any more than 5% of most arrays and 5% of the fences, repeat data from these small areas sampled from our previous year resulted in large sampling bias when extrapolated to the much larger Project elements. Furthermore, after conducting fatality searches for more than a year, it became apparent that avian fatalities accounted for >99% of all fatality finds, and that a sufficient proportion of fatalities (22.6% of all small carcasses and 63.6% of all large carcasses) persisted past the weekly search interval. Together, these reasons led to the decision to cease repeat searches at the CVSR Project.

Despite our decision to stop repeat searches at CVSR, short-interval searches could potentially play an important role in areas with higher scavenging rates and at sites where a large proportion of animals could be scavenged without leaving sign. Also, at sites with higher rates of fatalities, a lower number of searched trackers may be sufficient for accurately estimating site-wide fatalities. However, this method should be implemented only after assessing fatality rates through reconnaissance searches.

4.1.3 Utility of Incidental Detections

Of the 35 fatalities found during this reporting period, only one was found by CVSR operations staff. Fatalities were rarely found in high-traffic areas such as roads, suggesting that data gathered from future incidental reporting will be very limited for analytical purposes. On their own, incidental detections are unlikely to provide enough data to allow tracking of trends in species found, seasonal variations, or trends across Project elements. Despite this limitation, ongoing reporting of these detections may yet assist in identifying and remediating major wildlife hazards on the Project site. The fatality that was discovered by CVSR Project staff during this reporting period was likely caused by electrocution, highlighting the role of the incidental detection protocol.

4.2 Fatality Trends: Cause of Death by Project Element

4.2.1 Fatalities by Cause of Death

4.2.1.1 Arrays

Among avian species expected to be affected by development of the Project, waterbirds were of particular concern. Because waterbirds are sometimes attracted to black-top parking lots or roads, and some solar facilities have reported finding high proportions of waterbirds (Horvath et al. 2009; Grippo et al. 2014; Kagan et al. 2014), obligate waterbirds could potentially be at risk at and near solar arrays. However, during the current year reporting period, only three waterbirds were detected in arrays at CVSR.

It is difficult to discern if waterbird fatalities were low because waterbirds were less attracted to the region during the drought, the birds didn't perceive the arrays as water, or for some other reason. Extreme drought conditions have led to longer-than-normal dry lake conditions in Soda Lake, approximately 2 miles (3 km) south of the Project site. This dry lake supports standing water only during wet years, when it is a major attractant for waterbirds to the region.

Except for the Evaporation Pond (where several waterbird species have been observed by HTH biologists), the Project site lacks aquatic habitats suitable for waterbirds. Therefore, the three waterbirds likely had confused the arrays for water bodies and either collided with a panel or landed in the array. Pied-billed grebes are obligate waterbirds and have difficulty taking flight from land because of the posterior position of their feet (Miller 1942;

Johnsgard 1987). American coots also spend a majority of their lives in water, but they are also capable of making short-distance movements on land. Considering the life history of these species and the lack of suitable habitat on site, the three fatalities were considered collisions; these individuals may have died from predation after they landed in the arrays and were unable to take off, or died from trauma stemming from collision.

A total of ten carcasses were found in the arrays during this reporting period. Of these, the probable cause of death could be established for only three. Previous studies of birds that have died from window collisions suggest that birds rarely have broken necks or other visible skeletal fractures, but intercranial hemorrhaging is almost always present (Klem 1991). Because we did not perform necropsies on whole carcasses found in the field, we were not able to definitively rule out collision as a possible cause of death. Cause of death determinations are further complicated by the possibility that survivors of collisions may be temporarily stunned, and made more susceptible to predation. Given these factors, the cause of death for whole carcasses found without signs of injury or disease were categorized as unknown.

4.2.1.2 Gen-tie Line and MVOH Line

The majority of fatalities found along the Gen-tie and MVOH Lines were located directly or nearly directly under these lines. This pattern suggests that many of these fatalities were caused by powerline collisions, and that the remains were indicative of scavenging, rather than predation. Brown and Drewien (1995) and many others have documented that high-tension powerlines contribute to avian mortality, and especially to the mortality of larger birds such as waterfowl. However, few large carcasses were detected during fatality searches of the Gen-tie and MVOH Lines. Instead, the majority of fatalities found were passerines, possibly reflecting the greater proportion of passerines that occur on the site. Nevertheless, these results suggest that the avian flight diverters installed on the Gen-tie Line may greatly reduce the risk of collisions with larger birds, but are not effective at diverting smaller birds.

In contrast to the fatalities found along the MVOH Line, fatalities found along the Gen-tie Line showed strong seasonal peaks in fall and late spring. Also, Gen-tie Line fatalities included migrant passerines not typically observed on the Project site or expected in the area. The Gen-tie Line and MVOH Line differ from each other in several respects: the Gen-tie Line follows a large elevational change, the lines are higher above the ground than the MVOH Line, and several bird species breed at a pond with tamarisk trees located directly below the Gen-tie Line. To help determine potential differences in fatality patterns between the two types of overhead lines, we produced graphs relating fatality number and species richness to tower number and elevation. These graphs did not suggest any clear linear trends or clustering near the tamarisk pond; fatalities were more or less equally distributed along the Gen-tie Line. Therefore, the differences in height between these two structures may be the main factor effecting differences in fatality rates and species richness of fatalities. The avian flight diverters on the Gen-tie Line appear to be largely ineffective in deterring these migrant and winter resident passerines, possibly because these birds are less apt to see overhead lines during nocturnal movements.

The tamarisk pond was not searched directly for the full year, to avoid disturbing nesting birds during the breeding season. In the fall, dense saltbush (*Atriplex* sp.) made some areas between the pond and Tower 17 impassable. Although the lack of fatality clustering on towers to either side of the tamarisk pond suggests that the higher avian use at the tamarisk pond does not result in a detectable increase in collision in the vicinity of the pond.

It is difficult to study how the mortality of large and small birds along the overhead lines compares with background mortality rates without having a linear control in the landscape. We know of no studies that control for background mortality rates along a linear corridor without an actual linear structure. Instead, most avian mortality studies of high-tension powerlines typically compare fatality rates of powerlines with or without avian flight-diverting structures (Brown and Drewien 1995; Janss and Ferrer 1998). Given that more passerine fatalities were documented along the CVSR Project powerlines than expected, and very few raptor fatalities were documented, a linear control would be useful in understanding how these fatality rates compare with background fatality rates for large and small avian groups in the Project area.

4.2.1.3 Control Plots

The control plots were designed as a way to quantify background levels of mortality on the Project site. All fatalities found in control plots were assigned an unknown cause of death, and all of these fatalities were included in a total fatality estimate that was used to define an adjustment factor for the site. For other research sites where preconstruction surveys are not a viable option, on-site control plots may provide similar data that could not otherwise be obtained. At CVSR, cause of death could not be determined for most array fatalities, so data from the control plots was useful in elucidating what percentage of array fatalities may be assigned to background (natural) causes, rather than indirect or direct Project-related causes.

4.2.1.4 Evaporation Pond

The Evaporation Pond represented a concern because evaporation ponds in xeric environments can attract birds and exposethem to elevated selenium and toxic salt levels. Additionally, the perimeter fence surrounding the pond was considered to represent a collision risk. However, the Evaporation Pond had the lowest number of fatalities during this reporting period, and all fatalities were found on the same day.

The only bird considered to have died from disease during this reporting period was found along the fence of the Evaporation Pond. Because this bird was extremely emaciated, disease seemed to be the plausible cause of death.

During the entire postconstruction monitoring period, Evaporation Pond levels were relatively low. Nonetheless, passerines and waterbirds were occasionally observed in and around the pond before searchers conducted fatality searches. As part of CVSR operations, a bird deterrence protocol (hazing and use of automated deterrence devices) was in place at the Evaporation Pond throughout the designated shorebird nesting season (February through July). These efforts likely resulted in less use of the pond by birds. Given that so few fatalities were detected at the pond, especially during time periods were active deterrence devices were not in use, risk of fatalities occurring at the pond appears to be low.

4.2.1.5 Fences

Few fatalities were detected along array perimeter fences, and only one was attributed to collision. Given the low number of fatalities found at this Project element, risk of fence collision as a whole appears to be low.

4.3 Fatality Estimates

4.3.1 Estimated Fatalities on the CVSR Project Site

During the period of 7 November 2013 to 6 November 2014 (the period used in the Fatality Estimator), there were an estimated 126 fatalities from known causes that occurred on the Project site (90% confidence interval: 106–155).

There were an estimated 2.24 fatalities per tracker (90% confidence interval: 1.83–2.87) from unknown or natural causes of death in the arrays. In control plots, there were an estimated 1.72 fatalities per control plot (90% confidence interval: 1.05–2.68). The confidence intervals for controls are considerably wider in part because fewer trackers were searched in control areas than in array areas for the year.

The confidence interval is much smaller this year, compared to the confidence interval of 3.09 fatalities per tracker reported last year, when we provided a fatality estimate for just Array 1 from nearly 1 year of data. Because we grouped all of the arrays' data, thus creating a larger sample size for a single fatality estimate, we more accurately estimated a fatality rate for the site as a whole. Additionally, by combining 2 years of carcass-persistence and searcher-efficiency data, we decreased the amount of uncertainty in our modeling parameters, which in turn decreased the amount of uncertainty in the fatality estimate as a whole.

Large-scale fatality searches at solar facilities have been a subject of interest since as early as the 1980s (e.g., Wagner et al. 1983), but the methods still vary in search intensity and regularity, fatality estimation methods used, and methods used for determining cause of death (e.g., Althouse and Meade 2014; HTH 2014a). Because of the differences among studies, comparison among rates of fatalities reported remains difficult. Although fatality rates per megawatt are often reported as a useful tool to compare rates among industrial sites and across energy types (Arnett et al. 2008; Smallwood 2013), it is easy to draw incorrect conclusions if the underlying methods differ and if different panel technologies are involved (e.g., a tracker unit generating 0.5 megawatts more than an alternative type may only be 7% larger).

4.3.2 Adjusting Fatality Rates on the CVSR Project Site

Observed fatalities within arrays that could be attributed to collision were limited (N=6 in 2013-2014); thus, fatality estimates at CVSR are primarily based upon fatalities where the cause of death or injury could not be determined. Adjusting these avian fatality rates by background fatality rates measured within control plots substantially reduced the estimated fatality rate that may be related to the CVSR Project. Whether placed within the context of per-acre of arrays or per-acre of tracker units, an annual mean background-adjusted fatality estimate of 526 fatalities indicates that there may be one fatality per 2.3 acres per year that cannot currently be explained by background fatality rates as measured in control plots.. These could be fatalities resulting from collision that leave no evidence of collision (or are moved away from the site of collision by scavengers), or increased fatality rates due to differential rates of avian use and/or predation within the arrays compared to the control plots.

We observed an increase of some avian species within the arrays. Mourning doves were the most common fatality in solar arrays, followed by horned larks and house finches, which combined accounted for 66% of all fatalities. During the first year of study, there were 44 point count detections of seven species perched on the developing arrays of solar panels. After the second year of study, the numbers had increased to 210 total detections of 13 species, including a merlin (*Falco columbarius*). After the third year of study, the numbers had increased to 578 total detections of 15 species; however, 81% of the tally consisted of house finches and mourning doves. Observations of horned larks during avian use surveys averaged higher in the array and Gen-tie survey areas than in the offsite survey areas throughout the study period, especially in winter (HTH 2015).

Modeling results indicated that activity rates for mourning doves increased in construction areas and remained high as the Project moved into the operational phase, suggesting a lasting attraction for these species (HTH 2015). Ninety-nine percent of the observations of mourning doves within the solar generation facility occurred in the arrays, either on the ground or perched on array structures (HTH 2015). Mourning doves are among the most widespread and abundant species in the country; Seamans and Sanders (2014) estimated that there are approximately 275 million mourning doves in the country, and their abundance appears to be stable in the West.

Surveyors at the CVSR Project documented use by scavenger/ predatory birds and mammals (San Joaquin kit fox [*Vulpes macrotis mutica*] and coyote [*Canis latrans*]). A merlin was observed perching and hunting in the developed solar arrays; also observed were a foraging red-tailed hawk and a foraging ferruginous hawk (*Buteo regalis*). Merlins eat mostly sparrow-sized to dove-sized birds (Warkentin et al. 2005) often specializing on hunting a couple of the most abundant species in an area, which would include horned larks, house finches, and mourning doves in the Project area. Each merlin can prey on 2.2 to 2.5 birds per day (Page and Whitacre 1975; Warkentin et al. 2005). They are known to flush flocks to take advantage of the confusion, which surveyors at CVSR have hypothesized may result in strikes with array infrastructure. Differential use of the arrays by avian species combined with predation by raptors, foxes, and coyotes could explain the current estimated difference between fatality rates within arrays and control plots.

We should point out that the sample size for control plots is low, and the number of fatalities within those control plots is even lower. Low sample size can easily lead to biases due to sampling error. Conducting bootstrap analysis on observed data inherently invokes an assumption that the observed data adequately represents the true state of the system. For example, in this case we must assume that the 14 fatalities detected in the 30 control plots (for the 2013/14 survey period) adequately represent fatality rates across all onsite Conservation Lands. Since the 30 control plots only cover a very small fraction of Conservation Lands, this assumption is tenuous. Furthermore, even though N_C trackers are sampled for each bootstrap iteration, they are drawn from the much larger N_T "population" of surveyed trackers (which represents approximately 20% of all trackers). As a result, we effectively sampled a large portion of the total number of trackers over the many bootstrap iterations, but the area over which we sampled control plots remains fixed and small. Therefore, some bias and imbalance remains in the bootstrapped results. We believe that these methods make the best use of the available data to control for background fatality in estimating fatality rates attributable to the CVSR Project and quantifying the uncertainty in those estimates.

In addition to the imbalance in sample area between control and array plots, there are several other factors that may influence these results. The proximity of control plots to arrays should be advantageous because we are comparing similar underlying habitats. However it is possible that fatality rates in lands immediately adjacent to the Project could be affected by their proximity to the Project, and thus would not adequately represent the background fatality rate of the area if the Project was absent all together. The large difference in estimated fatality rates between this year, and the 2013 annual report likely represents a reduction in avian use as continued drought widely impacted bird populations and nesting behavior (Section 4.1.1). Noting this difference among years stresses the importance of comparing fatality rates during the same time periods over successive years, because changes in bird population abundance and behavior may greatly affect analysis results.

More research is needed to address the issue of background fatality rates versus fatality rates attributable to solar photovoltaic projects. Study designs that include avian use studies within arrays and control plots, and studies that balance sample sizes within arrays and control plots would address many of the limitations of this analysis.

4.3.3 Carcass-persistence Rates

Although previous studies have monitored the overall persistence of carcass sign (e.g., feather spots), the practice has not been universally adopted (Balcomb 1986; Hager et al. 2012). Nevertheless, we chose to focus on overall persistence times, rather than time to scavenging alone, because feather spots represent an important source of data for fatality searches. Although some information is lost after scavenging, feather spots may still provide some degree of certainty about cause of death, by their location (e.g., directly under a powerline) and species identification (e.g., feather spots from waterbirds species may lend credibility to the idea that individuals of the species mistake the arrays for water). The results of our carcass-persistence trials revealed that, whereas average scavenging times were less than a week for both small and large carcasses across seasons, average persistence times ranged from 5 days to 30 days. The results also suggest that, although season has a strong influence on scavenging time, it has considerably less influence on overall persistence time. Instead, size seems to have a strong impact on persistence time: small carcasses are much more likely to be removed completely during scavenging, whereas large carcasses tend to leave feather spots behind.

In our study, we were careful to avoid scavenger swamping. Although some previous studies (e.g., Wagner et al. 1983, Ponce et al. 2010, and Derby et al. 2007) likely overloaded the capacity of local scavengers to effectively dispose of placed carcasses (Smallwood et al. 2010), the smaller numbers of carcasses we placed each week helped to ensure that we recorded accurate scavenging times. Still, several carcasses were visited several times before they were scavenged. Kit foxes are one of the few scavenger species present in the area that is capable of food caching (Clark pers. comm.), but they too sometimes visited carcasses without attempting to remove them. Because we made a concerted effort to use fresh carcasses, we feel that this pattern simply highlights the highly opportunistic nature of scavenging.

Our results suggest that, although scavenging times may differ by 1–2 days by season, persistence time of feather spots is most affected by the vegetation height and density where the carcass is placed. Although this may seem self-evident, the effects of vegetation height on carcass persistence has received limited attention in previous studies of carcass persistence or fatality estimates, and it may have significant implications for fatality estimates at sites where ground vegetation is cleared or purposely kept short, particularly when search intervals are longer than a week.

4.3.4 Searcher-efficiency Rates

Overall searcher-efficiency rates between 2012 and 2014 were comparable to efficiency rates at other wind and solar energy facilities, where rates have ranged from 32% to 67% (Nicholson et al. 2005; Derby et al. 2007; Leslie et al. 2012; Johnston et al. 2013; Martin et al. 2013).

Our study incorporated feather spots along with carcasses in the searcher-efficiency trial design. Feather spots are rarely incorporated into fatality studies, but many fatality studies report a majority of fatalities from feather spots (Derby et al. 2007; WEST 2004; Johnston et al. 2013; Martin et al. 2013; Althouse and Meade 2014), either because scavenging is rapid or because there are longer search intervals. Thus, visibility associated with the condition of the fatality is rarely representative of true conditions and could affect fatality estimates. In our study, fatality searchers were most effective at finding large carcasses and large feather spots in easy visibility conditions, and least effective at finding small feather spots in both easy and moderate visibility conditions, and at finding small carcasses in moderate visibility conditions. When attempting to recover a missed trial specimen in one of the latter three classes, and even when standing within a few feet of the specimen, searchers often had difficulty visually locating it. Undoubtedly, these fatality types were difficult to detect because they blend in with vegetation, even when vegetation height is low. The large differences in detectability between carcasses and feather spots point to the importance of incorporating feather spots into studies, to yield more robust fatality estimates.

Section 5.0 Recommendations

During the course of this fatality monitoring study, we have identified areas where further research is needed to guide the design of future fatality monitoring studies at utility-scale solar facilities. The following recommendations outline research areas and measures that we believe are important.

- Projects covering large amounts of area may have a significant portion of fatalities from natural background mortality. To determine the contribution of background mortality, a spatially balanced study employing control plots similar in size, layout, and overall total area, should be used to estimate background fatality rates with comparable accuracy to the developed project site.

- Focused research on the causes of feather spots and the average number of feather spots created from a single fatality should be considered.

- If site-wide fatality monitoring is deemed necessary and the primary goal is to determine annual operational fatality rates, then site-wide fatality monitoring should be started once the full project becomes operational and for at least one year. Fatality searches phased in as portions of the project become operational can be used to document fatalities prior to site-wide searches, and to conduct searcher efficiency and carcass persistence trials to develop the survey design. Fatality monitoring survey design, including spatial coverage requirements and survey frequency can be optimized after the collection of preliminary data.

- Intensive daily repeat fatality surveys are not necessary to conduct fatality estimates. The reduced spatial and temporal coverage of these intensive surveys may lead to less precise estimates when extrapolated to obtain site-wide annual estimates, and are only recommended when required to link timing of fatalities to specific events (e.g., weather patterns or operational changes).

- Avian use studies should consider bird census techniques that are potentially more effective in documenting species richness and relative abundance of birds in project areas that will be covered by arrays. Typical point count study designs may not be effective at detecting birds that tend to remain concealed under panels during counts. Line transect methods may provide a better index of avian use before and after construction. Birds under panels will likely be more visible from line transects oriented perpendicular to the array tracker rows than they would be from fixed-location point count sites located outside the arrays. If possible, line transect survey intervals should mirror fatality search intervals, to assess whether fatality rates correspond with bird activity levels. If survey intervals cannot mirror fatality search intervals, we recommend a minimum of monthly avian activity searches using line transects to determine relative abundance and trends in populations during periods of avian fatality monitoring.

- Projects incorporating high-tension powerlines should assess whether the project site is located in an important route for migratory songbirds. Because many migratory songbirds fly at night, typical deterrence devices that have been successful with raptors may not be as effective at preventing collisions by songbirds.

- To assess fatalities along linear project features such as powerlines, study designs should incorporate linear controls, to provide background mortality rates for such features.

- To the extent practicable, powerlines should not be placed over wetland features, where large numbers of birds may roost and nest. Wetland features, such as the tamarisk wetland along the Gen-tie Line, provide habitat for common and sensitive species, such as the tricolored blackbird (*Agelaius tricolor*), now emergency-listed under the California Endangered Species Act.

- We recommend that necropsies be performed on a subset of carcasses when practicable, especially when external injuries are not present; birds that have died because of collisions may not have external signs of injury, but typically exhibit intercranial hemorrhaging that can be identified during a necropsy. Performing necropsies on a subsample of carcasses may lead to more information about the cause of death.

- The use of scent dogs in fatality monitoring efforts should be considered to increase the accuracy and narrow the confidence level of fatality estimates, especially in areas with high density vegetation. Scent dogs have been shown to be more efficient at detecting some fatality classes than human searchers and have a higher likelihood of detecting rare events than humans, given equal levels of survey effort (HTH, unpublished data). Studies on sites with varying topography, complex habitat features, and dense vegetation may benefit from scent dog searches because the dogs rely on olfactory, rather than visual, cues.

- Feather spots should be incorporated into bias-trial protocols to produce more robust fatality estimates and to provide more comparable industry-wide fatality estimates, especially for studies with longer search intervals.

Appendix A. Avian Species Used in Searcher-efficiency Trials, September 2012 to November 2014 (N = 434)

Species	Carcass Size	Number of Fatality Plants Placed[1]
Acorn woodpecker (*Melanerpes formicivorus*)	Large	1[2]
America coot (*Fulica americana*)	Large	9
American crow (*Corvus brachyrhynchos*)	Large	11
American kestrel (*Falco sparverius*)	Large	1
Band-tailed pigeon (*Patagioenas fasciata*)	Large	6
Barn owl (*Tyto alba*)	Large	5
Black-crowned night heron (*Nycticorax nycticorax*)	Large	1
Black-headed grosbeak (*Pheucticus melanocephalus*)	Small	1
Brewer's blackbird (*Euphagus cyanocephalus*)	Small	4
Brown-headed cowbird (*Molothrus ater*)	Small	6
Burrowing owl (*Athene cunicularia*)	Large	1
California quail (*Callipepla californica*)	Large	12
California towhee (*Melozone crissalis*)	Small	1
Cedar waxwing (*Bombycilla cedrorum*)	Small	1
Chestnut-backed chickadee (*Poecile rufescens*)	Small	1
Cliff swallow (*Petrochelidon pyrrhonota*)	Small	8[2]
Common raven (*Corvus corax*)	Large	16
Common yellowthroat (*Geothylpis trichas*)	Small	1
Cooper's hawk (*Accipiter cooperii*)	Large	12
Eared grebe (*Podiceps nigricollis*)	Large	1
Eurasian collared-dove (*Streptopelia decaocto*)	Large	7
European starling (*Sturnus vulgaris*)	Small	2
Great horned owl (*Bubo virginianus*)	Large	16
Greater roadrunner (*Geococcyx californianus*)	Large	4
Green heron (*Butorides virescens*)	Large	2
Horned lark (*Eremophila alpestris*)	Small	36
House finch (*Carpodacus mexicanus*)	Small	53
House sparrow (*Passer domesticus*)	Small	17
Lark sparrow (*Chondestes grammacus*)	Small	2
Lesser goldfinch (*Spinus psaltria*)	Small	1
Lincoln sparrow (*Melospiza lincolnii*)	Small	3
Long-eared owl (*Asio otus*)	Large	3
Mourning dove (*Zenaida macroura*)	Large	70
Red-shouldered hawk (Buteo lineatus)	Large	30[2]
Red-tailed hawk (*Buteo jamaicensis*)	Large	2
Rock pigeon (*Columba livia*)	Large	15

Species	Carcass Size	Number of Fatality Plants Placed[1]
Savannah sparrow (*Passerculus sandwichensis*)	Small	7
Sharp-shinned hawk (*Accipiter striatus*)	Large	1
Short-eared owl (*Asio flammeus*)	Large	1
Swainson's thrush (*Catharus ustulatus*)	Small	2
Unknown small	Small	3
Unknown large	Large	1
Unknown raptor	Large	3
Unknown songbird	Small	3
Varied thrush (*Ixoreus naevius*)	Small	1
Warbling vireo (*Vireo gilvus*)	Small	1
Western meadowlark (*Sturnella neglecta*)	Small	25
Western scrub-jay (*Aphelocoma californica*)	Small	2
White-crowned sparrow	Small	2
White-tailed kite (*Elanus leucurus*)	Large	1
Yellow warbler (*Setophaga petechia*)	Small	9
Yellow-billed magpie (*Pica nuttalli*)	Large	7
Yellow-rumped warbler (*Dendroica coronata*)	Small	3

Notes:
[1] Numbers represent both carcasses and feather spots placed
[2] One individual was removed by a scavenger

Appendix B. Avian Species Used in Carcass-persistence Trials (N=206)

Species	Carcass Size	Number Placed
Acorn woodpecker (*Melanerpes formicivorus*)	Small	6
American coot (*Fulica americana*)	Large	4
American crow (*Corvus brachyrhynchos*)	Large	18†
American goldfinch (*Spinus tristis*)	Small	2
American kestrel (*Falco sparverius*)	Large	3
American robin (*Turdus migratorius*)	Large	3
Anna's hummingbird (*Calypte anna*)	Small	3
Band-tailed pigeon (*Patagioenas fasciata*)	Large	3†
Barn owl (*Tyto alba*)	Large	5†
Black turnstone (*Arenaria melanocephala*)	Large	1
Brewer's blackbird (*Euphagus cyanocephalus*)	Small	6
Blackbird sp.	Small	1
Bullock's oriole (*Icterus bullockii*)	Small	1
Bushtit (*Psaltriparus minimus*)	Small	2
California gull (*Larus californicus*)	Large	1
California thrasher (*Toxostoma redivivum*)	Small	1
California quail (*Callipepla californica*)	Large	2*
California towhee (*Melozone crissalis*)	Small	4
Cedar waxwing (*Bombycilla cedrorum*)	Small	2
Cliff swallow (*Petrochelidon pyrrhonota*)	Small	4
Common raven (*Corvus corax*)	Large	2
Cooper's hawk (*Accipiter cooperii*)	Large	1
Eurasian collared-dove (*Streptopelia decaocto*)	Large	7
European starling (*Sturnus vulgaris*)	Small	4
Great horned owl (*Bubo virginianus*)	Large	9
Greater roadrunner (*Geococcyx californianus*)	Large	2
Hermit thrush (*Catharus guttatus*)	Small	1
Horned grebe (*Podiceps auritus*)	Large	2
Horned lark (*Eremophila alpestris*)	Small	3
House finch (*Haemorhous mexicanus*)	Small	16
House sparrow (*Passer domesticus*)	Small	6†
House wren (*Troglodytes aedon*)	Small	2
Lesser goldfinch (*Spinus psaltria*)	Small	2
Lincoln's sparrow (*Melospiza lincolnii*)	Small	1
Mourning dove (*Zenaida macroura*)	Large	11*
Northern flicker (*Colaptes auratus*)	Large	2
Northern fulmar (*Fulmarus glacialis*)	Large	1
Northern mockingbird (*Mimus polyglottos*)	Small	5

Species	Carcass Size	Number Placed
Nuttall's woodpecker (*Picoides nuttallii*)	Small	3
Peregrine falcon (*Falco peregrinus*)	Large	1
Pine siskin (*Spinus pinus*)	Small	1
Red-necked phalarope (*Phalaropus lobatus*)	Small	1†
Red-shouldered hawk (*Buteo lineatus*)	Large	7†
Red-tailed hawk (*Buteo jamaicensis)*	Large	9†
Red-winged blackbird (*Agelaius phoeniceus*)	Small	2
Rock dove/pigeon (*Columba livia*)	Large	4
Ruby-crowned kinglet (*Regulus calendulai*)	Small	1
Savannah sparrow (*Passerculus sandwichensis*)	Small	2
Sharp-shinned hawk (*Accipiter striatus*)	Large	1†
Song sparrow (*Melospiza melodia*)	Small	1
Western bluebird (*Sialia mexicana*)	Small	1
Western meadowlark (*Sturnella neglecta*)	Large	1
Western screech-owl (*Megascops kennicottii*)	Large	5
Western scrub-jay (*Aphelocoma californica*)	Small	9
White-crowned sparrow (*Zonotrichia leucophrys*)	Small	4
White-tailed kite (*Elanus leucurus*)	Large	2†
Yellow-rumped warbler (*Setophaga coronata*)	Small	2

Notes:
* = Reclassified:
- One California quail was a nestling and was classified as a small carcass.
- Two mourning doves were juveniles and were classified as small carcasses.

† Excluded from analysis:
- Two American crows were excluded from analysis because full persistence data were lacking.
- One band-tailed pigeon was excluded from analysis because full persistence data were lacking.
- One barn owl was excluded from analysis because full persistence data were lacking.
- One house sparrow was excluded from analysis due to removal by biologist prior to scavenging.
- One red-necked phalarope was excluded from analysis due to camera malfunctioning.
- One red-shouldered hawk was excluded from analysis because full persistence data were lacking.
- Two red-tailed hawks were excluded from analysis because full persistence data were lacking.
- One sharp-shinned hawk was excluded from analysis because full persistence data were lacking.
- One white-tailed kite was excluded from analysis because full persistence data were lacking.

Appendix C. Weekly Fatality Search Results: 16 August 2013 to 17 November 2014

Incident ID	Site	Search Date	AOU Code[1]	Observation Details	Cause of Death[2]	% Certainty	UTM Zone	Easting	Northing
20130828-41	34.5kV Line	8/28/2013	UNWA	Feather spot: 16 primaries and secondaries, four tail, and 40+ contour feathers from unknown warbler.	C	>50	11S	236786	3913033
20131002-51	34.5kV Line	10/2/2013	SAVS	Whole carcass: no obvious sign of injury but feathers falling out of chest from possible collision point.	C	>90	11S	234643	3913250
20131023-46	34.5kV Line	10/23/2013	AMKE	Feather spot: all feather types. At least >100 body feathers and >12 wing and tail feathers.	C	>50	11S	233929	3913261
20131113-41	34.5kV Line	11/13/2013	MODO	Feather spot: 5-6 contours in clumps	U	n/a	11S	238157	3912540
20131113-106	34.5kV Line	11/13/2013	MODO	Feather spot: 50 body and 3 primary feathers.	C	>50	11S	234646	3913264
20131113-107	34.5kV Line	11/13/2013	CORA	Feather spot: 30 body feathers.	U	n/a	11S	234458	3913361
20131120-91	34.5kV Line	11/20/2013	MODO	Feather spot: 3 Tail feathers. 9 body feathers found clumped	U	n/a	11S	234645	3913250
20131204-26	34.5kV Line	12/4/2013	BUOW	Feather spot: 50+ body feathers	U	n/a	11S	238214	3912029
20131211-41	34.5kV Line	12/11/2013	WEME	Feather spot: Three flight feathers (all tail) and 15 to 20 body feathers.	C	>50	11S	238150	3912327
20140108-124	34.5kV Line	1/8/2014	BUOW	Feather spot: 10+ flight and body feathers.	U	n/a	11S	234808	3912884
20140108-125	34.5kV Line	1/8/2014	MODO	Feather spot: 100+ body and flight feathers.	U	n/a	11S	238146	3912249

Notes: UTM = Universal Transverse Mercator.

[1] Codes are designated by the American Ornithologists' Union (AOU) Check-list of North American Birds, and are defined in Table 5. Codes for unknown species are not designated by the AOU. For purposes of this report, unknown large bird, small bird, raptor, or passerine are designated as UNKN. Unknown warblers are designated as UNWA.

[2] Causes of death: C = collision; D = disease; E = electrocution; P = predation; U = unknown.

* = Clearance fatality

[1] Codes are designated by the American Ornithologists' Union (AOU) Check-list of North American Birds, and are defined in Table 5. Codes for unknown species are not designated by the AOU. For purposes of this report, unknown large bird, small bird, raptor, or passerine are designated as UNKN. Unknown warblers are designated as UNWA.

[2] Causes of death: C = collision; D = disease; E = electrocution; P = predation; U = unknown.

* = Clearance fatality

Appendix G. Fatality Data Errata for CVSR ABPP Annual Postconstruction Fatality Report, 16 August 2012 to 15 August 2013

Incident ID	Site	Search Date	Species Code[1]	UTM Zone	Easting	Northing	Observation Details	Errata Notes
20120927-1	Array 1	9/27/2012	MODO	11S	233981	3915723	Feather spot: >10 body feathers	Later determined to be feathers from roosting and preening mourning doves. Remove from the record.
20121127-103	Array 2 North	11/27/2012	MODO	11S	234496	3915315	Feather spot: Ten body feathers	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-104	Array 2 North	11/27/2012	HOLA	11S	234475	3915069	Feather spot: Ten+ body, five secondary, eight covert, and six primary feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-102	Array 2 North	11/27/2012	MODO	11S	234372	3915321	Feather spot: ten + body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-101	Array 2 North	11/27/2012	MODO	11S	234368	3915324	Feather spot: Body feathers	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-1	Array 2 North	11/27/2012	LEOW	11S	234062	3915269	Feather spot: ten + body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-300	Array 2 North	11/27/2012	HOLA	11S	234407	3914929	Feather spot: ten primary and ten+ body feathers	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-200	Array 2 North	11/27/2012	WEME	11S	234484	3915273	Feather spot: ten+ body and four primary feathers	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-201	Array 2 North	11/27/2012	HOLA	11S	234384	3915103	Feather spot: approximately 25 flight feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-11	Array 2 South	11/27/2012	MODO	11S	233636	3914428	Feather spot: two tail feathers and several body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.

Note:

[1] Codes are designated by the American Ornithologists' Union Check-list of North American Birds, and are defined in Table 5. Codes for unknown species are not designated by the AOU. For purposes of this report, unknown large bird, small bird, raptor, or passerine are designated as UNKN.

Incident ID	Site	Search Date	Species Code[1]	UTM Zone	Easting	Northing	Observation Details	Errata Notes
20121127-3	Array 2 South	11/27/2012	MODO	11S	234115	3914603	Feather spot: >10 body feathers	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-2	Array 2 South	11/27/2012	MODO	11S	233967	3914604	Feather spot: >10 body feathers	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-6	Array 2 South	11/27/2012	MODO	11S	234182	3914887	Feather spot: >10 body feathers	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-7	Array 2 South	11/27/2012	MODO	11S	234166	3914885	Feather spot: >10 body feathers	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-8	Array 2 South	11/27/2012	UNKN	11S	234174	3914646	Feather spot: two primary feathers and approximately ten body feathers from unknown RODO-sized bird.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121127-9	Array 2 South	11/27/2012	MODO	11S	234071	3914509	Feather spot: body feathers and three primaries	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121204-16	Array 2 South	12/4/2012	MODO	11S	233692	3914434	Feather spot: 15+ body and two tail feathers, and one secondary feather,	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121204-21	Array 2 South	12/4/2012	MODO	11S	234074	3914506	Feather spot: two flight and 50+ body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121204-13	Array 2 South	12/4/2012	CORA	11S	234245	3914577	Feather spot: two flight feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20121204-3	Array 2 South	12/4/2012	UNKN	11S	233883	3914885	Feather spot: two primary feathers with a few body feathers from unknown large bird.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130107-1	Array 8 Circuit 2	1/7/2013	HOLA	11S	233519	3912284	Feather spot: ten+ primary and 20+ body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130107-20	Array 8 Circuit 2	1/7/2013	MODO	11S	233740	3912137	Feather spot: Few tertiary and 20 body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130107-21	Array 8 Circuit 2	1/7/2013	MODO	11S	233986	3911832	Feather spot: three primary, two secondary, and one body feather.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.

Note:

[1] Codes are designated by the American Ornithologists' Union Check-list of North American Birds, and are defined in Table 5. Codes for unknown species are not designated by the AOU. For purposes of this report, unknown large bird, small bird, raptor, or passerine are designated as UNKN.

Incident ID	Site	Search Date	Species Code[1]	UTM Zone	Easting	Northing	Observation Details	Errata Notes
20130107-11	Array 8 Circuit 2	1/7/2013	MODO	11S	234117	3911957	Feather spot: 15+ body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-44	Array 4	1/9/2013	MODO	11S	235594	3912563	Feather spot: Six retrices and 20 contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-45	Array 4	1/9/2013	EUST	11S	235610	3912878	Feather spot: ten primary, nine secondary, two tertials, and ten contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-6	Array 4	1/9/2013	MODO	11S	235905	3912709	Feather spot: seven secondary and 40+ contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-7	Array 4	1/9/2013	MODO	11S	235609	3912839	Feather spot: eight retrices and ten+ contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-31	Array 4	1/9/2013	MODO	11S	235608	3912813	Feather spot: seven primary, ten secondary, and 50+ contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-32	Array 4	1/9/2013	MODO	11S	235568	3912818	Feather spot: four tail, two secondary, and seven contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-26	Array 4	1/9/2013	MODO	11S	235603	3913901	Feather spot: seven retrices and 20+ contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-41	Array 4	1/9/2013	MODO	11S	235601	3913521	Feather spot: two retrices and 25+ contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-8	Array 5	1/9/2013	MODO	11S	236647	3915788	Feather spot: four retrices and five contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-27	Array 5	1/9/2013	MODO	11S	236668	3913775	Feather spot: five retrices, one secondary, three wing coverts, and two primary feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130109-46	Array 5	1/9/2013	MODO	11S	236702	3913640	Feather spot: four retrices two secondary and 20+ contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.

Note:

[1] Codes are designated by the American Ornithologists' Union Check-list of North American Birds, and are defined in Table 5. Codes for unknown species are not designated by the AOU. For purposes of this report, unknown large bird, small bird, raptor, or passerine are designated as UNKN.

Incident ID	Site	Search Date	Species Code[1]	UTM Zone	Easting	Northing	Observation Details	Errata Notes
20130114-1	Array 8 Circuit 2	1/14/2013	MODO	11S	233450	3912428	Feather spot: four wing coverts, 50 contour, and three primary feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130116-11	Array 4	1/16/2013	MODO	11S	235677	3912709	Feather spot: two retrices, two secondary, and 15 breast feathers.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130123-	Array 4	1/23/2013	MODO	11S	235639	3913403	Feather spot: four tail, four primary, two secondary, and 40 contour feathers.	Incidental fatality was not reported in 2012-2013 report. Include in the record.
20130123-46	Gen-tie Line	1/23/2013	LASP	11S	234390	3917813	Feather spot: two fresh primaries. Found in wetland area.	Species was incorrectly identified as LOSH, but was later correctly identified as a LASP. Revise species to lark sparrow in the record.
20130214-6	Array 1	2/14/2013	WEME	11S	234022	3915705	Feather spot: 20+ flight feathers and over 100 body feathers.	UTM coordinates were incorrect. Coordinates are correct herein.
20130220-46	34.5kV Line	2/20/2013	MODO	11S	234612	3913242	Feather spot: five+ tail and 30+ body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130508-36	34.5kV Line	5/8/2013	UNKN	11S	233833	3911676	Feather spot: approximately 15 body feathers and one flight feather from unknown small bird.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130508-82	Array 4	5/8/2013	HOFI	11S	235724	3913524	Feather spot: seven wing feathers still attached and one secondary feather.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130508-6	Gen-tie Line	5/8/2013	WAVI	11S	234450	3914310	Whole carcass: possible broken neck and possible power line collision.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130509-56	Array 1	5/9/2013	HOLA	11S	234156	3915632	Feather spot: mostly body feathers, some primary feathers.	Fatality was not reported in 2012-2013 annual report. Include in the record.

Note:

[1] Codes are designated by the American Ornithologists' Union Check-list of North American Birds, and are defined in Table 5. Codes for unknown species are not designated by the AOU. For purposes of this report, unknown large bird, small bird, raptor, or passerine are designated as UNKN.

Incident ID	Site	Search Date	Species Code[1]	UTM Zone	Easting	Northing	Observation Details	Errata Notes
20130514-56	Array 2 North	5/14/2013	UNKN	11S	234342	3915286	Feather spot: cranium/skull covered by feathers from unknown small bird.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130515-57	Gen-tie Line	5/15/2013	HOFI	11S	234582	3914702	Partial carcass: Top half of wing.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130515-58	Gen-tie Line	5/15/2013	YRWA	11S	234424	3917882	Feather spot: approximately 10 flight feathers and 30 body feathers.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130515-56	Gen-tie Line	5/15/2013	UNKN	11S	234707	3915476	Feather spot: body and primary feathers from unknown small bird.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130529-72	Gen-tie Line	5/29/2013	YEWA	11S	234265	3917142	Feather spot: approximately 100 body feathers and 15 flight feathers.	Species was incorrectly identified as YRWA, but was later correctly identified as YEWA. Revise species to YEWA in the record.
20130529-28	Gen-tie Line	5/29/2013	YRWA	11S	234296	3917715	Feather spot: 12 flight and 30 body feathers. Found directly under the powerline.	Species was identified as warbler sp., but later correctly identified as YRWA. Revise to YRWA in the record.
20130604-46	Array 2 South	6/4/2013	CORA	11S	234368	3914685	Feather spot: approximately 35 body feathers.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130613-41	Array 1	6/13/2013	EUST	11S	234294	3915204	Partial carcass: two primaries, clump of body feathers, and part of wing.	Fatality was not reported in 2012-2013 annual report. Include in the record.
20130619-41	34.5kV Line	6/19/2013	HOSP	11S	235931	3912655	Feather spot: five flight and 15 contour feathers found directly under the powerline.	UTM Coordinates incorrect in 2012-2013 annual report. Coordinates should be revised as 11S 235931 m E 3912655 m N in the record.
20130626-46	Conservation Lands	6/26/2013	BUOW	11S	234199	3912839	Feather spot: approximately 20 pin feathers.	Incidental fatality was not reported in 2012-2013 annual report. Include in the record.
20130708-21	Array 6	7/8/2013	HOFI	11S	237194	3913141	Feather spot: Single distinct clump of 15+ body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.

Note:

[1] Codes are designated by the American Ornithologists' Union Check-list of North American Birds, and are defined in Table 5. Codes for unknown species are not designated by the AOU. For purposes of this report, unknown large bird, small bird, raptor, or passerine are designated as UNKN.

Incident ID	Site	Search Date	Species Code[1]	UTM Zone	Easting	Northing	Observation Details	Errata Notes
20130708-22	Array 6	7/8/2013	CORA	11S	237101	3912945	Feather Spot, Skin: ten primary and secondary feathers, 20-30 single contour feathers, three+ clumps of body feathers, and some skin fragments.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130708-23	Array 6	7/8/2013	HOLA	11S	237752	3912687	Feather spot: 100+ body feathers, eight flight feathers (primaries and secondaries), one leg, half of beak with attached lore and malar feathers, bone and skin fragments including eye socket.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130708-71	Array 6	7/8/2013	LASP	11S	234028	3911758	Feather spot: 100+ body feathers and about 12 flight feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130708-26	Array 6	7/8/2013	ROPI	11S	237689	3912612	Feather spot: 30 contour feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130708-27	Array 6	7/8/2013	BRBL	11S	237691	3912611	Feather spot: 100+ body feathers and 20 flight feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.
20130709-61	Array 7	7/9/2013	HOLA	11S	237689	3912656	Feather spot: approximately three flight feathers, two tail feathers and 40 body feathers.	Clearance fatality was not reported in 2012-2013 annual report. Include in the record.

Note:
[1] Codes are designated by the American Ornithologists' Union Check-list of North American Birds, and are defined in Table 5. Codes for unknown species are not designated by the AOU. For purposes of this report, unknown large bird, small bird, raptor, or passerine are designated as UNKN.

VP FOSSIL AND SOLAR OPERATIONS

9. TYPE OF PERMIT
MIGRATORY BIRD SPECIAL PURPOSE UTILITY PERMIT - SOLAR

10. LOCATION WHERE AUTHORIZED ACTIVITY MAY BE CONDUCTED

Records Location: 44810 Kaiser Road, Desert Center, CA 92239
Carcasses Collection Location: T4S,R15E, Sections 9, 10, 13, 14, 15, 22, 23, 24.
Carcasses Stored: In freezer on site at collection location.

11. CONDITIONS AND AUTHORIZATIONS:

A. GENERAL CONDITIONS SET OUT IN SUBPART D OF 50 CFR 13, AND SPECIFIC CONDITIONS CONTAINED IN FEDERAL REGULATIONS CITED IN BLOCK #2 ABOVE, ARE HEREBY MADE A PART OF THIS PERMIT. ALL ACTIVITIES AUTHORIZED HEREIN MUST BE CARRIED OUT IN ACCORD WITH AND FOR THE PURPOSES DESCRIBED IN THE APPLICATION SUBMITTED. CONTINUED VALIDITY, OR RENEWAL, OF THIS PERMIT IS SUBJECT TO COMPLETE AND TIMELY COMPLIANCE WITH ALL APPLICABLE CONDITIONS, INCLUDING THE FILING OF ALL REQUIRED INFORMATION AND REPORTS.

B. THE VALIDITY OF THIS PERMIT IS ALSO CONDITIONED UPON STRICT OBSERVANCE OF ALL APPLICABLE FOREIGN, STATE, LOCAL, TRIBAL, OR OTHER FEDERAL LAW.

C. VALID FOR USE BY PERMITTEE NAMED ABOVE.

This permit does not supersede any State Requirements. You are responsible for ensuring that you are in compliance with all State laws, including but not limited to California Fish and Game Code 3511 (fully protected species) 3503.5 and 3513. For additional information on State requirements please contact: California Department of Fish and Wildlife, Magdalena Rodriguez, 909-945-3294.

D. **Possession and transport.**

1) You and subpermittees are authorized to collect, transport and temporarily possess carcasses and partial remains of birds protected under the Migratory Bird Treaty Act, **except Bald Eagles and Golden Eagles (Eagles)** and species listed as **Threatened or Endangered** under the U.S Endangered Species Act (see 50 CFR § 17.11), found at the location/property specified in Block 10 for monitoring bird mortality associated with operation of the wind facility. To accurately determine species fatality rates, the monitoring study must include standardized carcass searches, searcher efficiency trials, and carcass removal by scavenger trials. For **Eagles and federally listed Threatened or Endangered Species** you must call a U.S. Fish and Wildlife Service (Service), Office of Law Enforcement (OLE) special agent for instructions and approval before collecting or moving the carcass or its parts. It may be necessary to preserve the carcass or its parts onsite until an agent or other Service or State representative arrives to collect it.

☒ ADDITIONAL CONDITIONS AND AUTHORIZATIONS ALSO APPLY

12. REPORTING REQUIREMENTS

ANNUAL REPORT DUE: 01/31
You must submit an annual report to your Regional Migratory Bird Permit Office each year, even if you had no activity. Form: www.fws.gov/forms/3-202-17.pdf.

ISSUED BY

TITLE
MIGRATORY BIRD PERMIT SPECIALIST

DATE
03/18/2015

Your OLE contact phone number is. **Your OLE point-of-contact is Special Agent (SA) Michael Clark, Michael_Clark@fws.gov, (702) 281-9071.**

2) Except for take caused by your infrastructure and operations, you may not collect or disturb and must immediately report to OLE any dead migratory birds that appear to have been poisoned, shot, or otherwise killed or injured as the result of potential criminal activity.

3) With prior approval from your Migratory Bird Permit Office, you are authorized to receive lawfully acquired carcasses and parts to use for standardized carcass searches, searcher efficiency trials, and carcass removal by scavenger trials from federally permitted rehabilitation centers or other lawful sources. You must maintain records of all acquisitions, including source (name of permittee and permit number), species, description (carcass or type of part), date of receipt, and final disposition.

E. **Data Collection.**

Mortality monitoring data should be compiled in the attached Excel spreadsheet and submitted to the Service on a monthly basis until directed differently by permit official. It includes but is not limited to the collection of the following information:

1) All relevant and applicable data associated with each carcass or part collection, or injured bird, should be recorded, including the information below. Required data are designated with an asterisk (*).

    a) discovery date*
    b) collection date*
    c) species*
    d) sex and age (juvenile/adult), if known
    e) condition of bird (alive or dead) *
    f) condition of carcass (entire, partial, scavenged)*
    g) description of carcass (e.g., intact, feather spot, headless, wing sheared, blood in mouth, entanglement)*
    h) interval since last search*
    i) observer*
    j) search method used, including opportunistic discovery of carcasses*
    k) weather conditions at likely time of death, if known*
    l) identifying information for the infrastructure element, e.g. solar panel, evaporation pond, fencing, building
    m) the GPS coordinates in decimal degrees for the location where carcass/part found*
    n) ground distance of carcass from pole, line, panel, or other structure (e.g pond or building)
    o) azimuth of carcass from solar panel or infrastructure (including GPS coordinates in decimal degrees), if known
    p) apparent cause of mortality/injury (collision, electrocution, drowned, other) *
    q) estimated date of mortality or estimate of time since death (e.g., <1 day, 1 day, 2-3 days)*
    r) habitat surrounding carcass (*e.g.*, desert, grassland, rural, urban, cropland, bare ground, tall grass)
    s) information on carcass or injured bird disposition*
    t) any special notes or additional information

2) All carcasses and partial remains collected should be digitally photographed, bagged, and labeled with the following information:

    1) date collected
    2) a unique specimen number
    3) the information listed in E(1)(l and m) above
    4) facility name

3) Migratory birds, **other than Eagles and federally listed Threatened or Endangered Species**, may be used for searcher efficiency trials and carcass removal trials AFTER a mortality report has been submitted to Regional Migratory Bird Permit Office per condition H(1)(e) documenting their death, all data collected in condition E(2), and the unique specimen number assigned to that carcass in condition E(3) above.

F. **Injured birds.** Injured migratory birds, including **eagles and federally listed threatened or endangered species,** must be transferred to a federally permitted migratory bird rehabilitator or a licensed veterinarian for care. Rehabilitation and/or veterinary costs are the utility's responsibility. See condition H for reporting instructions.

G. **Take and collection of live, non-injured migratory birds, eggs, or nests is not authorized by this permit.** In addition, this permit does not authorize the take, capture, harassment or disturbance of **eagles or federally listed endangered or threatened species** (see 50 CFR 17.11).

H. **Reporting.**

1) You must report bird injuries and deaths in accordance with the time frames specified below (a-c).

a. You must submit a written report of avian mortality and injury **monthly** to OLE, the Regional Migratory Bird Permit Office (RMBPO), the Ecological Service's Field Office (Field Office) and California Department of Fish and Wildlife (CDFW). Your report must include as much of the data listed in condition E above that is available for each incident. In addition, we request that you voluntarily report bat injury and mortality information.

- OLE RAC: Erin Dean, (erin_dean@fws.gov, phone: 310-328-1516)
- RMBPO: Heather Beeler (heather_beeler@fws.gov, phone: 916-414-6651)
- Field Office-Palm Springs: (jody_fraser@fws.gov , phone: 760-322-2070)
- CDFW: Email to CDFW at: (armand.gonzales@wildlife.ca.gov and magdalena.rodriguez@wildlife.ca.gov)

b. In addition to the monthly reports, you must report any **bald eagle or golden eagle or threatened or endangered species** found dead or injured to the OLE and each contact listed in H(1)(a) immediately if possible, but no later than **24 hours after discovery.** Your report must include as much of the information from condition E that is available for each incident. A written mortality or injury report specific to the eagle or listed species must be submitted to all contacts listed in condition H(1)(a), to include the data in condition E, no later than **one week (7 days)** from the date of discovery of the carcass.

A list of Threatened and Endangered species by State may be found in the Service's Threatened and Endangered Species System (TESS) database at: *<http://www.fws.gov/endangered>*.

c. In the event that you discover 6 or more migratory birds that have been injured or killed within a 24 hour period, you must report the event to RMBPO and the Field Office listed in condition H(1)(a) above immediately if possible, but no later than the **next business day**. This summary must list the number of events by species. Within 14 days of carcass/injury discovery, a written mortality or injury report specific to the incident must be submitted to your FWS contacts, and should include as much of the data in E above as possible. This reporting requirement is intended to inform the Service of events or other variables that may have contributed to the mortality event.

2) You must submit an **Annual Report** of dead and injured birds, **including Eagles and Threatened and Endangered Species**, discovered and/or collected to your Migratory Bird Permit Office by January 31 following each calendar year in which the permit is in effect. Your written annual report is due by 1/31/14. The report form 3-202-17 is available at *<http://www.fws.gov/forms/3-202-17.pdf>*. Please submit a Special Purpose Utility Excel Data in lieu of using form 3-202-17. All of the information requested on the 3-202-17 form, including the signed certification statement, must be included.

I. **Disposition of Carcasses and Parts.**

1) In accordance with Condition D (1) above, the Service OLE will advise you on disposition of **eagle and threatened or endangered species** specimens. The special agent will advise if they will recover an eagle carcass or if you need to ship the carcass to the Service. With prior written authorization from an OLE special agent, you may ship carcasses directly to the National Eagle Repository (NER) (contact the NER at 303-287-2110 for shipping instructions). The written authorization from the special agent must accompany the eagle if it is shipped to the NER. Disposition must be reported in your final to your migratory bird permit issuing office.

2) Migratory Bird carcasses and parts (**other than eagles and threatened and endangered species**) collected during the duration of this permit must be stored in a freezer at the facilities at the location specified in Block 10. After receiving written permission from OLE and notification to your RMBPO, carcasses may be:
   a) used for searcher efficiency and scavenger removal trials; carcasses used in trials must be reported to the Service as outlined in Condition E(4) and H(1)(d) above. Heavily damaged carcasses should be excluded for use in these trials.
   b) donated to a public scientific or educational institution or to an individual or entity authorized by federal permit to acquire and possess migratory bird specimens.

All dead specimens and parts (except eagles and threatened and endangered species) that you do not transfer to another authorized party must be disposed of as directed by OLE.

J. **Renewal**. In addition to an updated monitoring protocol, any request for renewal of this permit must include information on the fatality rates of affected species or fatality patterns, analysis of those rates/patterns, whether any adjustments or measures were taken to avoid or minimize mortalities, and if so, any preliminary results of those modifications.

K. **Subpermittees.** Any person who is employed by or under contract to the permittee for the activities specified in this permit, or is otherwise designated as a subpermittee in writing by the permittee may exercise the authority of this permit.

L. **Standard Conditions.** You and any subpermittees must comply with the attached **Standard Conditions for Migratory Bird Special Purpose Utility Salvage Permits. These standard conditions are a continuation of your permit conditions and must remain with your permit.**

This permit does not supersede any State Requirements. You are responsible for ensuring that you are in compliance with all State laws, including but not limited to California Fish and Game Code 3511 (fully protected species) 3503.5 and 3513. For additional information on State requirements please contact: California Department of Fish and Wildlife, Deborah Hawk, 760-872-1126.

This permit does not, nor shall it be construed to, authorize lethal take or injury of migratory birds or limit or preclude the U.S. Fish and Wildlife Service from exercising its authority under any law, statute, or regulation, or from taking enforcement action against any individual, company, or agency. This permit is not intended to relieve any individual, company, or agency of its obligations to comply with any applicable Federal, State, Tribal, or local law, statute, or regulation.

This permit may be amended at any time in response to changes in national guidance or take reported.

MIGRATORY BIRD SPECIAL PURPOSE UTILITY PERMIT - SOLAR

10. LOCATION WHERE AUTHORIZED ACTIVITY MAY BE CONDUCTED

Records Location: 44810 Kaiser Road, Desert Center, CA 92239
Carcasses Collection Location: T4S,R15E, Sections 9, 10, 13, 14, 15, 22, 23, 24.
Carcasses Stored: In freezer on site at collection location.

11. CONDITIONS AND AUTHORIZATIONS:

A. GENERAL CONDITIONS SET OUT IN SUBPART D OF 50 CFR 13, AND SPECIFIC CONDITIONS CONTAINED IN FEDERAL REGULATIONS CITED IN BLOCK #2 ABOVE, ARE HEREBY MADE A PART OF THIS PERMIT. ALL ACTIVITIES AUTHORIZED HEREIN MUST BE CARRIED OUT IN ACCORD WITH AND FOR THE PURPOSES DESCRIBED IN THE APPLICATION SUBMITTED. CONTINUED VALIDITY, OR RENEWAL, OF THIS PERMIT IS SUBJECT TO COMPLETE AND TIMELY COMPLIANCE WITH ALL APPLICABLE CONDITIONS, INCLUDING THE FILING OF ALL REQUIRED INFORMATION AND REPORTS.

B. THE VALIDITY OF THIS PERMIT IS ALSO CONDITIONED UPON STRICT OBSERVANCE OF ALL APPLICABLE FOREIGN, STATE, LOCAL, TRIBAL, OR OTHER FEDERAL LAW.

C. VALID FOR USE BY PERMITTEE NAMED ABOVE.

This permit does not supersede any State Requirements. You are responsible for ensuring that you are in compliance with all State laws, including but not limited to California Fish and Game Code 3511 (fully protected species) 3503.5 and 3513. For additional information on State requirements please contact: California Department of Fish and Wildlife, Magdalena Rodriguez, 909-945-3294.

D. **Possession and transport.**

1) You and subpermittees are authorized to collect, transport and temporarily possess carcasses and partial remains of birds protected under the Migratory Bird Treaty Act, **except Bald Eagles and Golden Eagles (Eagles)** and species listed as **Threatened or Endangered** under the U.S Endangered Species Act (see 50 CFR § 17.11), found at the location/property specified in Block 10 for monitoring bird mortality associated with operation of the wind facility. To accurately determine species fatality rates, the monitoring study must include standardized carcass searches, searcher efficiency trials, and carcass removal by scavenger trials. For **Eagles and federally listed Threatened or Endangered Species** you must call a U.S. Fish and Wildlife Service (Service), Office of Law Enforcement (OLE) special agent for instructions and approval before collecting or moving the carcass or its parts. It may be necessary to preserve the carcass or its parts onsite until an agent or other Service or State representative arrives to collect it.

☒ ADDITIONAL CONDITIONS AND AUTHORIZATIONS ALSO APPLY

12. REPORTING REQUIREMENTS

ANNUAL REPORT DUE: 01/31
You must submit an annual report to your Regional Migratory Bird Permit Office each year, even if you had no activity. Form: www.fws.gov/forms/3-202-17.pdf.

ISSUED BY	TITLE	DATE
	MIGRATORY BIRD PERMIT SPECIALIST	03/18/2015

Your OLE contact phone number is. **Your OLE point-of-contact is Special Agent (SA) Michael Clark, Michael_Clark@fws.gov, (702) 281-9071.**

2) Except for take caused by your infrastructure and operations, you may not collect or disturb and must immediately report to OLE any dead migratory birds that appear to have been poisoned, shot, or otherwise killed or injured as the result of potential criminal activity.

3) With prior approval from your Migratory Bird Permit Office, you are authorized to receive lawfully acquired carcasses and parts to use for standardized carcass searches, searcher efficiency trials, and carcass removal by scavenger trials from federally permitted rehabilitation centers or other lawful sources. You must maintain records of all acquisitions, including source (name of permittee and permit number), species, description (carcass or type of part), date of receipt, and final disposition.

E. **Data Collection.**

Mortality monitoring data should be compiled in the attached Excel spreadsheet and submitted to the Service on a monthly basis until directed differently by permit official. It includes but is not limited to the collection of the following information:

1) All relevant and applicable data associated with each carcass or part collection, or injured bird, should be recorded, including the information below. Required data are designated with an asterisk (*).

   a) discovery date*
   b) collection date*
   c) species*
   d) sex and age (juvenile/adult), if known
   e) condition of bird (alive or dead) *
   f) condition of carcass (entire, partial, scavenged)*
   g) description of carcass (e.g., intact, feather spot, headless, wing sheared, blood in mouth, entanglement)*
   h) interval since last search*
   i) observer*
   j) search method used, including opportunistic discovery of carcasses*
   k) weather conditions at likely time of death, if known*
   l) identifying information for the infrastructure element, e.g. solar panel, evaporation pond, fencing, building
   m) the GPS coordinates in decimal degrees for the location where carcass/part found*
   n) ground distance of carcass from pole, line, panel, or other structure (e.g pond or building)
   o) azimuth of carcass from solar panel or infrastructure (including GPS coordinates in decimal degrees), if known
   p) apparent cause of mortality/injury (collision, electrocution, drowned, other) *
   q) estimated date of mortality or estimate of time since death (e.g., <1 day, 1 day, 2-3 days)*
   r) habitat surrounding carcass (*e.g.*, desert, grassland, rural, urban, cropland, bare ground, tall grass)
   s) information on carcass or injured bird disposition*
   t) any special notes or additional information

2) All carcasses and partial remains collected should be digitally photographed, bagged, and labeled with the following information:
   1) date collected
   2) a unique specimen number
   3) the information listed in E(1)(l and m) above
   4) facility name

3) Migratory birds, **other than Eagles and federally listed Threatened or Endangered Species**, may be used for searcher efficiency trials and carcass removal trials AFTER a mortality report has been submitted to Regional Migratory Bird Permit Office per condition H(1)(e) documenting their death, all data collected in condition E(2), and the unique specimen number assigned to that carcass in condition E(3) above.

F. **Injured birds.** Injured migratory birds, including **eagles and federally listed threatened or endangered species,** must be transferred to a federally permitted migratory bird rehabilitator or a licensed veterinarian for care. Rehabilitation and/or veterinary costs are the utility's responsibility. See condition H for reporting instructions.

G. **Take and collection of live, non-injured migratory birds, eggs, or nests is not authorized by this permit.** In addition, this permit does not authorize the take, capture, harassment or disturbance of **eagles or federally listed endangered or threatened species** (see 50 CFR 17.11).

H. **Reporting.**

1) You must report bird injuries and deaths in accordance with the time frames specified below (a-c).

a. You must submit a written report of avian mortality and injury **monthly** to OLE, the Regional Migratory Bird Permit Office (RMBPO), the Ecological Service's Field Office (Field Office) and California Department of Fish and Wildlife (CDFW). Your report must include as much of the data listed in condition E above that is available for each incident. In addition, we request that you voluntarily report bat injury and mortality information.

- OLE RAC: Erin Dean, (erin_dean@fws.gov, phone: 310-328-1516)
- RMBPO: Heather Beeler (heather_beeler@fws.gov, phone: 916-414-6651)
- Field Office-Palm Springs: (jody_fraser@fws.gov , phone: 760-322-2070)
- CDFW: Email to CDFW at: (armand.gonzales@wildlife.ca.gov and magdalena.rodriguez@wildlife.ca.gov)

b. In addition to the monthly reports, you must report any **bald eagle or golden eagle or threatened or endangered species** found dead or injured to the OLE and each contact listed in H(1)(a) immediately if possible, but no later than **24 hours after discovery.** Your report must include as much of the information from condition E that is available for each incident. A written mortality or injury report specific to the eagle or listed species must be submitted to all contacts listed in condition H(1)(a), to include the data in condition E, no later than **one week (7 days)** from the date of discovery of the carcass.

A list of Threatened and Endangered species by State may be found in the Service's Threatened and Endangered Species System (TESS) database at: <*http://www.fws.gov/endangered*>.

c. In the event that you discover 6 or more migratory birds that have been injured or killed within a 24 hour period, you must report the event to RMBPO and the Field Office listed in condition H(1)(a) above immediately if possible, but no later than the **next business day**. This summary must list the number of events by species. Within 14 days of carcass/injury discovery, a written mortality or injury report specific to the incident must be submitted to your FWS contacts, and should include as much of the data in E above as possible. This reporting requirement is intended to inform the Service of events or other variables that may have contributed to the mortality event.

2) You must submit an **Annual Report** of dead and injured birds, **including Eagles and Threatened and Endangered Species**, discovered and/or collected to your Migratory Bird Permit Office by January 31 following each calendar year in which the permit is in effect. Your written annual report is due by 1/31/14. The report form 3-202-17 is available at <*http://www.fws.gov/forms/3-202-17.pdf*>. Please submit a Special Purpose Utility Excel Data in lieu of using form 3-202-17. All of the information requested on the 3-202-17 form, including the signed certification statement, must be included.

I. **Disposition of Carcasses and Parts.**

1) In accordance with Condition D (1) above, the Service OLE will advise you on disposition of **eagle and threatened or endangered species** specimens. The special agent will advise if they will recover an eagle carcass or if you need to ship the carcass to the Service. With prior written authorization from an OLE special agent, you may ship carcasses directly to the National Eagle Repository (NER) (contact the NER at 303-287-2110 for shipping instructions). The written authorization from the special agent must accompany the eagle if it is shipped to the NER. Disposition must be reported in your final to your migratory bird permit issuing office.

2) Migratory Bird carcasses and parts (**other than eagles and threatened and endangered species**) collected during the duration of this permit must be stored in a freezer at the facilities at the location specified in Block 10. After receiving written permission from OLE and notification to your RMBPO, carcasses may be:
   a) used for searcher efficiency and scavenger removal trials; carcasses used in trials must be reported to the Service as outlined in Condition E(4) and H(1)(d) above. Heavily damaged carcasses should be excluded for use in these trials.
   b) donated to a public scientific or educational institution or to an individual or entity authorized by federal permit to acquire and possess migratory bird specimens.

All dead specimens and parts (except eagles and threatened and endangered species) that you do not transfer to another authorized party must be disposed of as directed by OLE.

J. **Renewal**. In addition to an updated monitoring protocol, any request for renewal of this permit must include information on the fatality rates of affected species or fatality patterns, analysis of those rates/patterns, whether any adjustments or measures were taken to avoid or minimize mortalities, and if so, any preliminary results of those modifications.

K. **Subpermittees.** Any person who is employed by or under contract to the permittee for the activities specified in this permit, or is otherwise designated as a subpermittee in writing by the permittee may exercise the authority of this permit.

L. **Standard Conditions.** You and any subpermittees must comply with the attached **Standard Conditions for Migratory Bird Special Purpose Utility Salvage Permits. These standard conditions are a continuation of your permit conditions and must remain with your permit.**

This permit does not supersede any State Requirements. You are responsible for ensuring that you are in compliance with all State laws, including but not limited to California Fish and Game Code 3511 (fully protected species) 3503.5 and 3513. For additional information on State requirements please contact: California Department of Fish and Wildlife, Deborah Hawk, 760-872-1126.

This permit does not, nor shall it be construed to, authorize lethal take or injury of migratory birds or limit or preclude the U.S. Fish and Wildlife Service from exercising its authority under any law, statute, or regulation, or from taking enforcement action against any individual, company, or agency. This permit is not intended to relieve any individual, company, or agency of its obligations to comply with any applicable Federal, State, Tribal, or local law, statute, or regulation.

This permit may be amended at any time in response to changes in national guidance or take reported.

Attachment A. Standard Conditions

Migratory Bird Special Purpose

Utility Salvage Permits
50 CFR 21.27

All of the provisions and conditions of the governing regulations at 50 CFR part 13 and 50 CFR 21.27 are conditions of your permit. Failure to comply with the conditions of your permit could be cause for suspension of the permit. The standard conditions below are a continuation of your permit conditions and must remain with your permit. If you have any questions regarding these conditions, refer to the regulations or, if necessary, contact your migratory bird permit issuing office. For copies of the regulations and forms, or to obtain contact information for your issuing office, visit: http://www.fws.gov/migratorybirds/mbpermits.html.

1. **Personal use.** This permit does not authorize personal use of any migratory birds, parts, nests or eggs salvaged, transported, or temporarily possessed under the authority of this permit.

2. **Banded Birds** (carcasses collected and injured birds) must be reported to the U.S. Geological Survey Bird Banding Laboratory at 1-800-327-2263 or *http://www.reportband.gov*. Information provided must include, as accurately as possible, species of bird, band number, date recovered, recovery location, and name and contact information of the person who recovered the carcass or bird.

3. **Subpermittees.** A subpermittee is an individual to whom you have provided written authorization to conduct some or all of the permitted activities in your absence. Subpermittees must be at least 18 years of age. As the permittee, you are legally responsible for ensuring that anyone conducting activities under your permit is adequately trained and adheres to the terms of your permit. You are responsible for maintaining current records of who you have designated as a subpermittee, including copies of designation letters you have provided.

4. **Carrying your permit.** You and any subpermittees must carry a legible copy of this permit and display it upon request of any duly authorized federal, state or tribal officer whenever exercising its authority. Subpermittees must also carry your written subpermittee designation letter.

5. **Records.** You must maintain complete and accurate records of the activities conducted and the data collected under this permit. You must keep all required records and collected wildlife parts relating to permitted activities at the location you identified in writing to the migratory bird permit issuing office. (50 CFR 13.46 and 21.27)

6. **Site inspections.** Acceptance of this permit authorizes the Director's agent to enter the utility property at any reasonable hour as necessary to inspect the wildlife, records, facilities, property, and associated infrastructure for wildlife impacted by the utility, and for compliance with the terms of this permit and governing regulations. (50 CFR 13.47)

7. **Applicable laws.** You may not conduct the activities authorized by this permit if doing so would violate the laws of the applicable State, county, municipal or tribal government or any other applicable law.

8. **Other permissions.** This permit does not authorize salvage of specimens on Federal, State, tribal, or other public or private property without additional prior written permits or permission from the agency/landowner/custodian.

Monitoring Schedule – Carcass Searches

- Carcass searches
  - Clearance survey (3 – 10 Feb)
  - Winter search (23 Feb to present)
  - Spring – 7 day interval
    - Begin 9 Mar, and continue weekly through May 31st
  - Summer: 21 day interval: June, July, August
  - Fall: Sept 1 – Oct 31
  - Winter: 21 day interval Nov. 1 – Feb 28th

Clearance Survey Results

- One feather spot
  - Common raven
  - Solar field
    - 17-05

Monitoring Schedule -SEEF

- Winter
  - Initial trial this week
  - Small – house sparrows
  - medium – rock pigeons and coturnix quail
  - large – hen pheasants and mallards
- Spring - 3 trials with ~1/3 total sample size for each
  - March
  - April
  - May

Monitoring Schedule – Carcass Persistence Trials

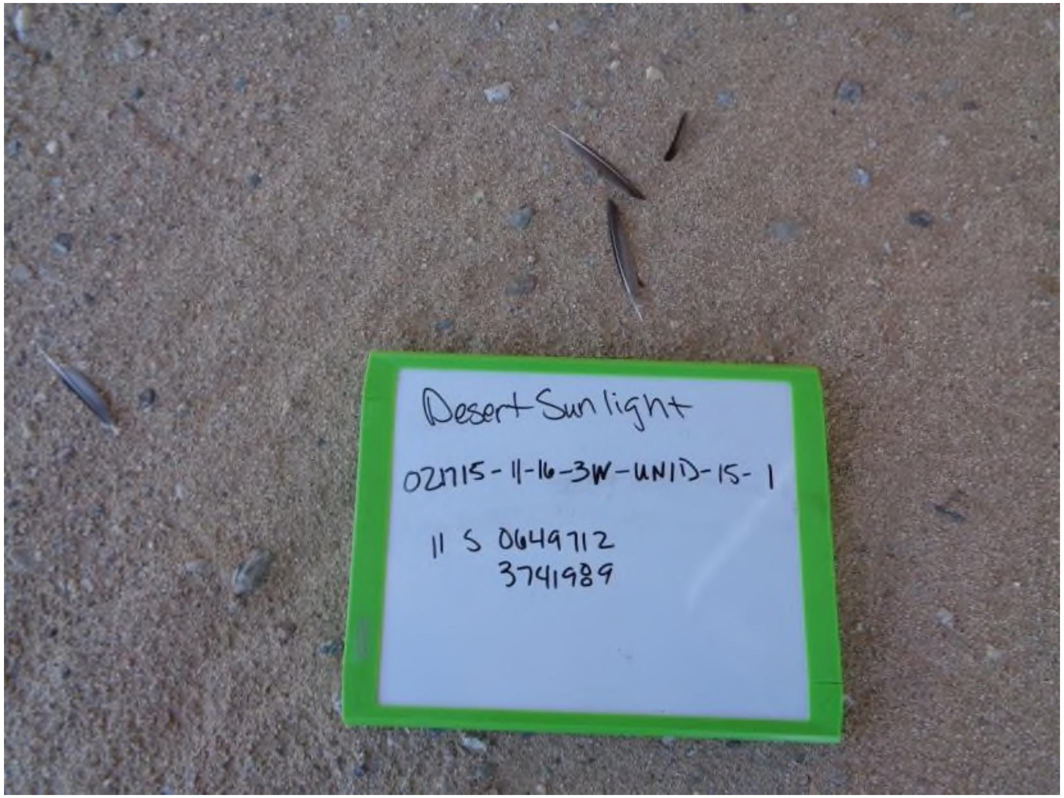
- 1 set of trials along gen-tie
- 1 set of trials within solar field/fence
- Began 17 Feb
- 8 carcasses with cameras (6 solar field/2 fence)
- 22 carcasses without cameras (15 gen-tie, 6 solar field/1 fence)
- N = 30 (1/2 trial)
- Same species as SEEF trials

2/21/2015 7:01 AM
Cuddeback Digital

KLM85 -12151-1
Cuddeback Digital
2/20/2015 1:02 AM

Incidentals

- One feather spot
  - Unknown species
  - Solar field
    - 11-16



Post-Construction Monitoring at the Genesis Solar Energy Project Riverside County, California

2015 Spring Report

Prepared for:

Genesis Solar LLC

700 Universe Blvd.,

Juno Beach, Florida 33408

Prepared by:

Western EcoSystems Technology, Inc.

415 West 17th Street, Suite 2000

Cheyenne, Wyoming

June 30, 2015

EXECUTIVE SUMMARY

Avian and bat monitoring surveys were conducted from March 05 to May 31, 2015 (the spring season) at Genesis Solar Energy Project (Project) in accordance with the Project's Bird and Bat Conservation Strategy (BBCS). Specifically, standardized carcass searches, searcher efficiency trials, and carcass persistence trials were conducted. This report represents the first seasonal report for the first year of monitoring, and summarizes monitoring methods and results for those surveys based on the procedures and requirements specified in the BBCS.

Standardized carcass searches were conducted 1) in the solar field, consisting of a random stratified 30% sample of solar troughs of both Project units, 2) at each evaporation pond, 3) along the perimeter of each power block and beneath each air condensed cooling (ACC) unit, 4) along inner and outer portions of the "fenceline", resulting in 100% of the length of the perimeter fence surveyed, and 5) along 25% of the total length of generation-tie (gen-tie) and distribution lines from the southernmost Project fence to Wiley's Well reststop, which co-occur with the Project access road. Searches were conducted within the spring season at intervals of approximately seven days.

All bird and bat fatalities and injuries that were discovered by observers, referred to as "detections" in this report, including those found incidentally and during standardized carcass searches, were documented. During the reporting period, 53 avian detections (including 2 stranded birds) were made, while there were no detections of bats.

According to specifications of the BBCS, avian detections were categorized by likely diurnal or nocturnal migration behavior, ecological guild (e.g., raptors, songbirds, etc.), facility component, and suspected cause of death. These standardized carcass search results, along with searcher efficiency and carcass persistence rates from bias trials conducted on site, were input into a fatality estimator model (Huso 2010) to provide a preliminary estimate of the number of fatalities that occurred at the Project during the reporting period adjusted for sources of bias. The estimate is considered preliminary because the annual report may pool information from bias trials and other data across seasons which could affect seasonal estimates.

Carcass persistence was influenced by carcass size. Small carcasses (0-100 g) had a 42.4% chance of persisting through the 7-day search interval, medium carcasses (101 – 999 g) had a 72.4% chance, and large carcasses (1000+ g) had an 84.5% chance. Mean removal time for small, medium, and large carcasses was 2.0, 7.3 and 14.6 days, respectively. In the solar field searcher efficiency was 92.3% over all carcass size classes. Along the gen-tie and distribution lines, searcher efficiency was influenced by carcass size: 42.9% for small birds, 100% for medium birds, and 100% for large birds.

Using the Huso (2010) fatality estimator model, during the spring period 2015, there were an estimated total 234 fatalities (90% confidence interval [CI]: 124 - 430) at the Project. Of these, 55 fatalities (23.4%) were estimated for the SCAs, 44 fatalities (18.6%) were estimated for the fence, 9 fatalities (4.0%) were estimated for evaporation ponds, 5 fatalities (2.2%) were estimated for power blocks, and 121 fatalities (51.8%; 90% CI: 32 - 307) were estimated for the gen-tie and distribution lines and project road. An estimated 113 (90% CI: 60 – 188) fatalities (0.065/acre, 0.434/nameplate MW) occurred for all components associated with both solar units (SCAs, power block, evaporation ponds, and along the perimeter fence, combined).

INTRODUCTION

Project Background

The Genesis Solar Energy Project (referred to in this report as "Project") consists of two solar power electrical generating facilities (Units 1 and 2) with a combined net capacity of 250 megawatts. The Project facility consists collectively of two power blocks, power generating equipment (solar collector assemblies [SCAs] of mirrored parabolic troughs [solar troughs or troughs]), support facilities, and evaporation ponds. Linear facilities include a transmission line, distribution line, natural gas pipeline, and a main access road that are mostly co-located for approximately 10.5 km (6.5 miles). The Project comprises approximately 1,800 acres (728 hectares [ha]). The solar field and associated structures comprise 1,727 acres (699 ha) and linear facilities comprise 93 acres (38 ha). The Project is located on land managed by the Bureau of Land Management (BLM) 25 miles (40 kilometers [km]) west of Blythe, in Riverside County, California (Figure 1).

Monitoring Plan Overview and Goals

A Bird and Bat Conservation Strategy (2015; “BBCS”) was prepared by the Project proponent in collaboration with the U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), California Energy Commission (CEC), and Bureau of Land Management (BLM) to guide comprehensive monitoring of impacts to birds and bats associated with operation of the Project. Final agency acceptance of the BBCS occurred in March 2015.

The BBCS details post-construction monitoring to be conducted and the data analysis and reporting processes that will be implemented by Genesis Solar in collaboration with the USFWS, CDFW, CEC, and BLM. As identified in the BBCS, they are:

1. Estimate overall annual avian fatality rate and species composition associated with the Project infrastructure. This estimate will include mortality associated with SCAs, overhead lines including the generation (gen-tie) line, perimeter fence and other features of the Project that may result in injury and fatality.
2. Determine whether there are spatial and temporal/seasonal patterns of mortality associated with project infrastructure (e.g., different fatality rates near SCAs on the edge of the solar field versus the interior area of the solar field).
3. Provide information that will assist the CEC and BLM, in consultation with the USFWS and the CDFW, in understanding which species and potentially which regional populations are at risk.
4. Collect data in such a way that the CEC and BLM, in consultation with the USFWS and CDFW, may make comparisons with other solar sites.

Purpose of This Report

This report represents the first seasonal report for the first year of monitoring summarizing monitoring methods and results for avian and bat fatalities and injuries based on the procedures and requirements specified in the approved BBCS and as required by CEC Condition of Certification BIO-16. This report covers the 2015 spring season, which includes the period from March 01 to May 31, 2015. As stated in the approved BBCS, this seasonal report includes the observed fatality rates broken out by likely diurnal, and likely nocturnal species, and for ecological guilds of interest (e.g., raptors, water-associated birds, passerines), for each of the facility types and suspected causes of death. Species composition of carcasses and the results of the bias trials are also reported. This report presents information related to the spatial distribution of carcasses, but no formal statistical analysis will be conducted until the end of the monitoring year, given the limited data presently available.

METHODS

The BBCS describes the methods by which monitoring and certain analyses, including compilation of the overall fatality estimate, will occur. Below is an abridged description (see BBCS for detailed methods).

Standardized Carcass Searches

This section describes areas surveyed, the timing and frequency of searches, and the methods by which standardized searches were conducted to identify dead/injured birds and bats at the Project. This section also describes the methods for conducting carcass removal and searcher efficiency trials; how data were reported and analyzed; and the methods for producing fatality estimates for the Project.

Areas Surveyed

Standardized carcass searches were conducted at a sample of the solar collector assemblies in each unit; the perimeter of each power block (including the area below each air condensed cooling [ACC] unit; Figures 2 and 3); the "fenceline" defined as the perimeter fences for each unit (100% of the total length of fence; Figures 2 and 3); and the gen-tie and distribution lines (25% of the total length of each line from the Project fence to Wiley's Well rest stop; Figure 4). Table 1 provides the total area of each component as well as the percent of each component that was searched.

To ensure a balanced distribution of plots in solar collector assemblies, each unit was divided into blocks, and each block was sampled using a systematic sample of 30% of pairs of rows with a random starting point. This sampling design ensures that survey plots were not spatially clumped.

Search Frequency and Timing

The spring survey season includes the period from March 01 through May 31, 2015. Standardized searches occurred at 7-day intervals beginning March 05, 2015. All project components included in standardized searches were surveyed 13 times.

The average spring search interval was 6.8 days (median 7 days) for all Project components included in standardized carcass searches. Slight variation in search interval was anticipated due to weather and logistical delays.

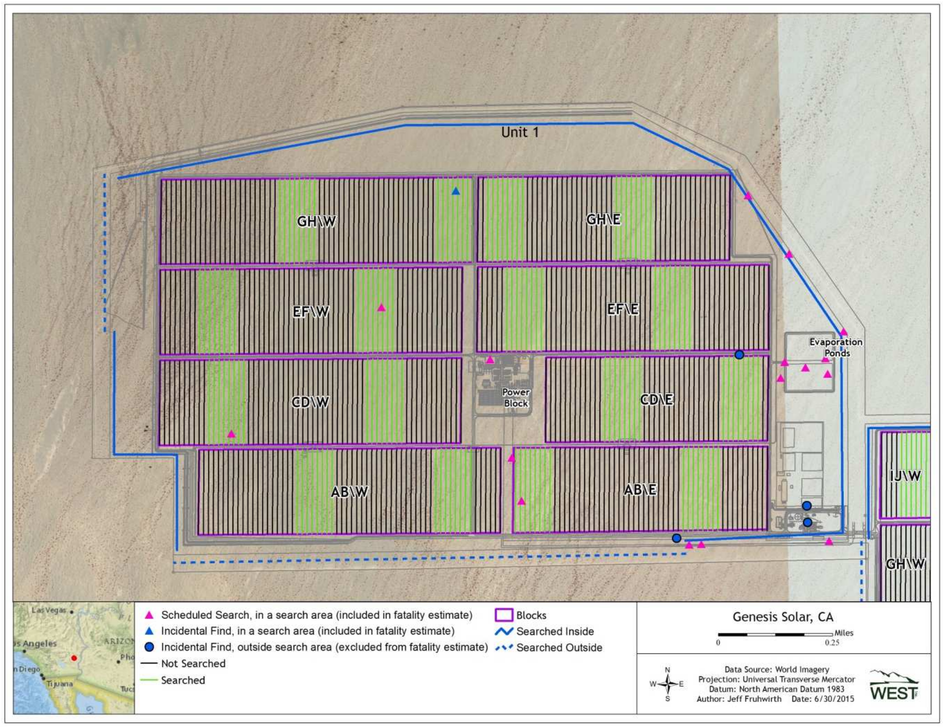

Figure 2. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance) at Unit 1 of the Genesis Solar Energy Project spring 2015.

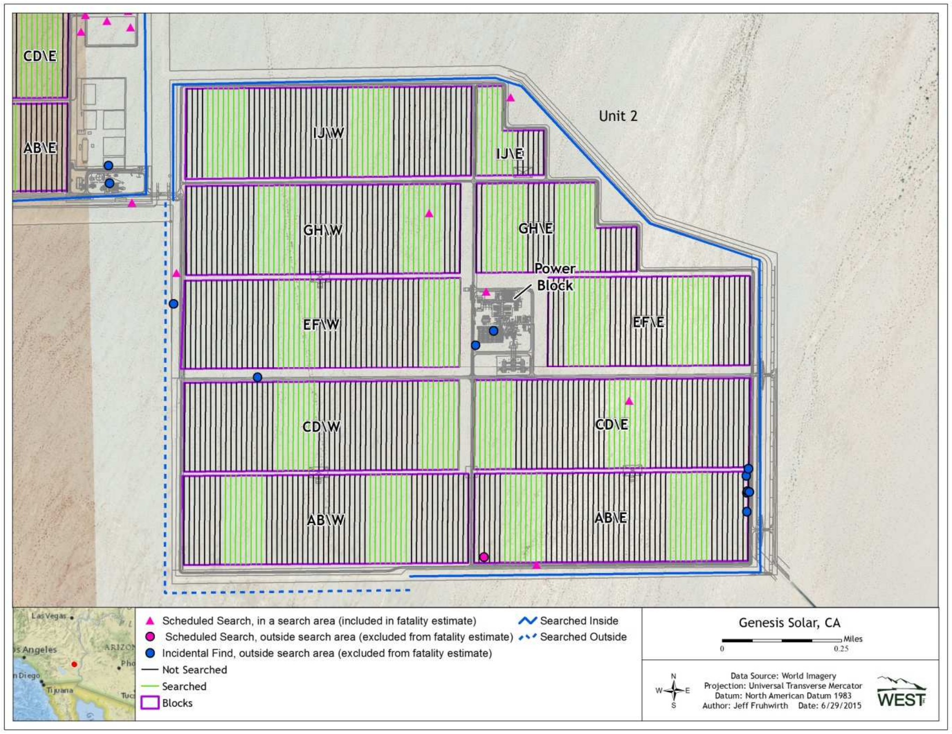

Figure 3. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance) at Unit 2 of the Genesis Solar Energy Project during spring 2015.

Table 1. Areas included in standardized carcass searches at the Genesis Solar Energy Project during spring 2015.

Project Component	**Total Size**	**Units**	**Percent of Component Searched**
SCAs	920	rows of solar troughs	30.4
Unit 1	460	rows of solar troughs	27.8
Unit 2	460	rows of solar troughs	33.0
ACC units	0.9	hectares	100
Power block (perimeter)	0.8	kilometers	100
Evaporation ponds	3.1	hectares	100
Distribution line	8.4	kilometers	25.0
Generation Tie line	8.4	kilometers	25.0
Fence	14.5	kilometers	100

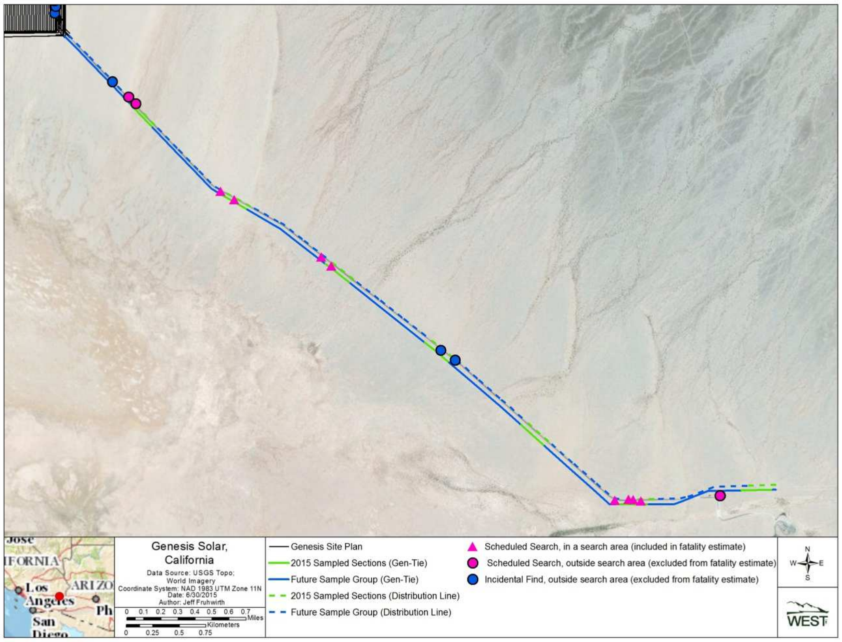

Figure 4. Areas of standardized searches and detections (those made during searches and those made incidental to operations and maintenance activities) along the distribution and generation tie lines and Project access road at the Genesis Solar Energy Project during spring 2015. Detailed maps of detections along both lines and the road are presented in Appendix C.

Search Methods

Standardized carcass searches were performed by CEC and BLM-approved biologists, in accordance with methods outlined in the BBCS.

Within the solar collector assemblies, 280 solar troughs (30.4% of the total number of troughs) were surveyed by vehicle. Biologists slowly drove (≤5 mph) parallel to troughs and centered between rows, searching ahead and to the driver's side of the vehicle for bird and bat carcasses. Biologists scanned out to a perpendicular distance of approximately 30 m, or the ground area encompassing two rows of solar troughs.

At each power block, biologists slowly walked around the entire perimeter looking for dead and injured birds and bats, and used binoculars to scan interior portions of the powerblock. Beneath ACC units, biologists walked four evenly-spaced transects through the gravel. The search area for the power block is defined as the 0.8 km of perimeter of each power block, and the area of the interior power block that was available for visual inspection from the periphery.

At each evaporation pond, biologists walked the entire perimeter looking for dead and injured birds and bats on the ground, in the netting, and in the pond below the netting. Binoculars or a spotting scope were used to scan across the top of the netting and the surface of each pond.

The entire length of fenceline (approximately 12 miles) was searched by vehicle. Biologists searched an approximately 1.5 to 2.5 miles (2.4 km) along drivable sections of the outside of the fence, and the remaining 9.5 to 10.5 miles (16.9 km) were surveyed from the inside of the fence (Figures 2 and 3). Travel speed was below five mph while searching.

The gen-tie and distribution lines were surveyed using a 15-m wide strip transect (i.e., 7.5 m of ground on either side of the overhead line). A 25% sample of both lines from the Project fence to the Project outer gate located near the Wiley's Well Road rest stop were searched for carcasses. Biologists slowly walked every fourth 300-ft segment of each line, scanning for dead or injured birds or bats within 7.5 m (24.6 ft) of the transect line. Given the location of the lines relative to the road, detections found in the strip transects below overhead lines could be caused by collision with an overhead line, vehicles along the road, or some combination of both.

Once a detection was made, suspected cause of death was assigned based on available evidence and proximity of a detection to Project infrastructure. Detections that had evidence of scavenging were assigned as “unknown” because it can’t be determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) had a suspected cause of death attributed to the respective Project component. However,~~m~~ it should be noted that there is substantial uncertainty associated with cause of death assignments because no events were directly observed.

Carcass Persistence Trials

Carcass persistence trials were conducted throughout the spring period. Carcasses from three size classes (small [0-100 g], medium [101-999], and large [1000+ g]) were used for trials. The small size class comprised house sparrows (*Passer domesticus*) and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons (*Columba livia*), and the large size class comprised hen mallard (*Anas platyrhynchos*) and hen ring-necked pheasant (*Phasianus colchicus*).

Carcass Persistence Data Collection

To quantify carcass persistence rates, 15 small, 10 medium, and five large carcasses were randomly placed and monitored within the SCAs (including the fence line), and the same number of each size class were placed along the gen-tie and distribution lines, for a total of 60 carcass persistence trials at Genesis during the spring 2015 season. Fifteen carcasses within the Project fence (within SCAs and along the fence and perimeter of power blocks) and four carcasses along the gen-tie and distribution lines were monitored using motion-triggered digital trail cameras, while the remaining carcasses were visited on foot, for 30 days or until the carcass had deteriorated to a condition at which it would no longer qualify as a documentable fatality. Fewer carcasses along the gen-tie and distribution lines were monitored with cameras because of theft and vandalism concerns. Carcasses without trail cameras were visited and photographed once per day for the first four days, and then every three to five days until the end of the monitoring period. To avoid training scavengers to recognize cameras as “feeding stations”, trail cameras were installed five days before specimens were placed, and fake cameras without bias trial carcasses were also placed (eight within the Project fence, and four along the gen-tie and distribution lines). Periodic ground-based checking of carcasses with trail cameras also occured to guard against misleading indicators of carcass removal, such as wind blowing the carcass out of the camera’s field of view. To minimize potential bias caused by scavenger swamping (Smallwood 2007, Smallwood et al. 2010), carcass-persistence specimens were distributed across the entire Project, not just in areas subject to standard searches, and trials were initiated in small numbers on four different dates throughout the spring season.

Estimating Carcass Persistence Times

Measurements of carcass persistence rates were subject to censoring. In this context, censoring refers to the instance when a value (e.g. days a carcass is present before being removed) may not be known exactly, but is known to be within a finite range. For example, suppose a carcass was checked on day 7 and was present, and was checked again on day 10, but was found to be missing. The exact time until removal is unknown; however, it is known that the carcass was available to be found for between 7 and 10 days. This carcass would be considered “interval censored”. Similarly, if a carcass lasts the entire 30-day trial period, that carcass is “right censored”— it is known that the carcass lasted at least 30 days, but it may have persisted longer.

There were four distributions implemented in survival models used to estimate the probability a carcass is unscavenged and available to be found at the end of the search interval (*r)*: exponential, Weibull, loglogistic, and lognormal. These four distributions exhibit varying degrees of flexibility in order to model a wide variety of distributions of persistence time. Akaike’s Information Criterion adjusted for sample size (AICc; Akaike 1973) was used to rank the fit of each survival model to observed carcass persistence data.

Searcher Efficiency Trials

Searcher efficiency trials were conducted throughout the spring period. Carcasses from three size classes (small, medium, and large) were used for trials. The small size class comprised house sparrows and 2-3 week old coturnix quail (*Coturnix coturnix*), the medium size class comprised rock pigeons, and the large size class comprised hen mallards and hen ring-necked pheasants.

Searcher Efficiency Data Collection

A total of 60 searcher efficiency trials (15 small birds, 10 medium birds, and five large birds within SCAs, power blocks, and along the perimeter fence, and the same number of each size class along the gen-tie and distribution lines) were placed at the Project during the 2015 spring season. Locations for trials were chosen by taking a randomized sample of all locations included in standardized carcass searches. Trials were placed in various vegetation heights and in areas that had different soil and vegetation colors and values to represent the range of conditions under which searches occur. They were placed in all areas where standardized searches occur except the evaporation ponds.

Estimating Searcher Efficiency

There were not sufficient data for the spring season to assess whether searcher efficiency differed by Project component (e.g., SCAs/fence/power block [SCAs] versus gen-tie/distribution line [overhead lines]), so searcher efficiency was assumed to differ between the two areas and was estimated separately for SCAs and overhead lines. The nearly complete lack of vegetation cover in the SCAs suggests that searcher efficiency may be higher in the SCAs than along the gen-tie and distribution lines where vegetation cover is greater. If this hypothesis is true, accounting for this difference in searcher efficiency across Project components will be important for producing accurate fatality estimates at the end of the monitoring year.

To evaluate hypotheses regarding differences in carcass detectability among carcass size and visibility classes, logistic regression models were fit to searcher efficiency data and AICc was used to compare models. Models including effects of carcass size (3 classes) and visibility index (2 classes) were compared to each other and the null model. The two visibility classes present at the Project site are: easy (defined as ≥ 90% bare ground [BG]; vegetation <6" tall) and moderate (defined as 26-89% BG; vegetation <6" tall). However, within the SCAs the moderate visibility class has a very limited spatial extent due to management aimed at minimizing vegetation cover and thus, was represented by only two trial carcasses during the reporting period. Rather than eliminating the two carcasses in the moderate class from the analysis of searcher efficiency, we assumed there were no differences in searcher efficiency between the two visibility classes in the SCAs this spring, and the set of candidate models for searcher efficiency (within the SCAs only) did not include tests of the hypothesis that searcher efficiency varied between visibility classes. Future analyses of searcher efficiency trials in the SCAs may include tests of the effect of visibility class, once sample size has sufficiently increased.

Comentado [FWS1]: What sample size is adequate for an estimate? This should be calculated seasonally, not in the aggregate.

Once the best model was chosen and appropriate classes identified, searcher efficiency, or the proportion of carcasses detected, *p,* was calculated for each class using the following equation:

$$p = \frac{Number\ of\ Carcasses\ Observed}{Number\ of\ Carcasses\ Available}$$

The data for this analysis included all searcher efficiency trial carcasses from the spring 2015 season.

Fatality Estimator

Fatality rate estimation is a complex task due to several variables inherent to every fatality monitoring study. Carcasses may persist for variable amounts of time due to local scavenger activity or environmental conditions leading to carcass degradation over time. Carcasses and feather spots are also detected with varying levels of success based on carcass characteristics and ground cover (e.g., vegetated areas underneath the gen-tie and distribution lines versus cleared areas beneath SCAs). For these reasons, it is generally inappropriate to draw conclusions based on the raw number of fatalities alone. The desire to estimate fatalities given these variables has driven the development of several statistical methods for estimating fatalities (e.g., Smallwood 2007, Huso 2010, Korner-Nievergelt 2011). All of these fatality estimation methods share a similar underlying model. Generally, the fatality estimation for a given site may be written as:

$$F=C/rp,$$

where *F* is the total number of fatalities, *C* is the number fatalities detected and included in fatality estimation*, r* is the probability a carcass is unscavenged and available to be found at the end of the search interval, and *p* is the probability of detecting a carcass (Huso 2010).

All fatality estimates were calculated using the Huso estimator, as well as 90% confidence using bootstrapping (Manly 1997). Bootstrapping is a computer simulation technique that is useful for calculating point estimates, variances, and confidence intervals for complicated test statistics. A total of 1,000 bootstrap replicates were used. The lower 5th and upper 95th percentiles of the 1,000 bootstrap estimates provide estimates of the lower limit and upper limit of an approximate 90% confidence interval on all estimates.

Incidental Reporting

Some detections were outside standardized search areas, or were within search areas but not observed during standardized searches. Such detections were found by WEST avian biologists and operational personnel and were considered “incidental” detections. When found by operational personnel, these detections were reported to WEST avian biologists for documentation. Data on incidental detections are reported here, as well as in the SPUT Avian Injury and Mortality Report Forms March – May 2015. All detections made in search areas were included in fatality estimates, regardless of whether they were detected incidentally or during searches.

MONITORING RESULTS

Summary of Avian Detections

During spring 2015, a total of 53 avian detections (including stranded birds and incidentals) of 23 identified species were recorded (Table 2). The most numerous detection of an identified species was Wilson's warbler (*Cardellina pusilla*), but with only three detections. Most detections (n = 22, or 41.5% of total detections) occurred beneath overhead lines (Figures 2, 3, and 4; Tables 2, 3, and 4), but those detections along the gen-tie and distribution lines are co-located with the road. Thirty-five (66.0%) detections were made during standardized carcass searches and 18 (34.0%) were documented as incidentals.

Common Name	Scientific Name	Migration Behavior*	Guild	Count	Project Component
Total				**53**	

* See literature cited for migration behavior references; information for most species was taken from the respective species accounts found in Birds of North America (BNA) Online (http://bna.birds.cornell.edu/bna/); where information on migration behavior was lacking in BNA accounts, Newton (2008) or Murray (2004) were used.

Temporal Patterns of Avian Detections

The number of detections recorded daily during spring 2015 ranged from zero to seven (Figure 5). The period from March 22 to May 17 was characterized by peaks in detections with a high on April 24. This event was reported to agencies per Special Purpose Utilities Permit Condition H(c). There was less variation in the number of detections per day after April 24. The number of detections per day represents those discovered during standardized carcass searches and incidentally.

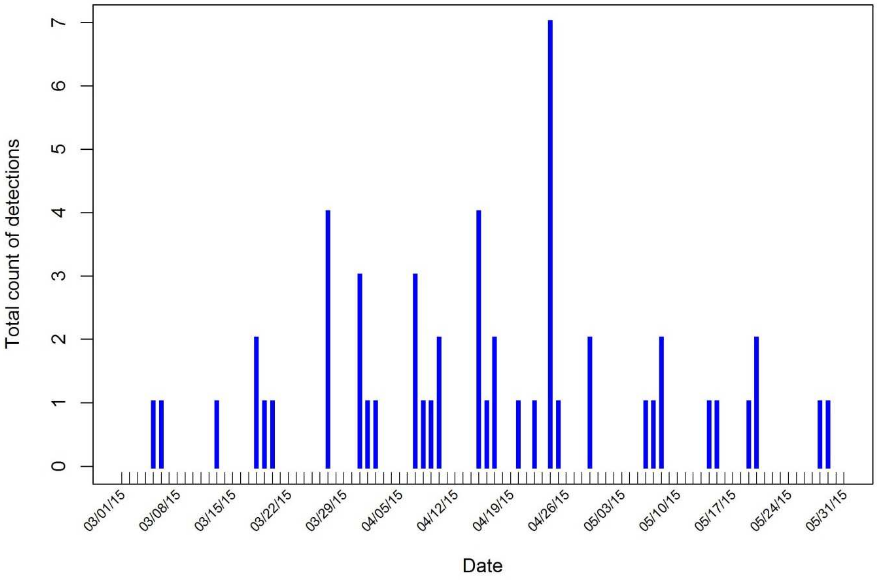

Figure 5. Total number of detections by date during spring 2015 at the Genesis Solar Energy Project, Riverside County, California.

Spatial Distribution of Avian Detections

Detections by Project Component

During spring 2015, detections were documented from the SCAs, power block or ACC unit within the power block, evaporation ponds, perimeter fence, gen-tie and distribution lines, road, water treatment plant, and storage units (Tables 2, 3, and 4). Of the 39 detections within the solar units 22 (56.4%) were detected in Unit 1, and 17 (43.6%) in Unit 2.

Table 3. Total avian detections by Project component and detection category during spring 2015 at the Genesis Solar Energy Project, Riverside County, California.

Project Component	Carcass search	Incidental	Percent of Total
Fence	10	1	20.8
Overhead lines/road	11	11	41.5
Pond	6	0	11.3
Powerblock	2	2	7.5
SCA	6	2	15.1
Storage Units	0	1	1.9
Water Treatment Plant	0	1	1.9
Percent of Total	66.0	34.0	100.0

Table 4. Total avian detections (including incidentals) by Project component and suspected cause of death during spring 2015 at the Genesis Solar Energy Project, Riverside County, California.

	Suspected Cause of Death*					
Project Component	**Collision**	**Drowned**	**Entangled**	**Predation**	**Unknown**	**Percent of Total**
Fence	2	0	0	0	9	20.8
Other	0	0	0	0	2	3.8
Overhead lines/road	14	0	0	1	7	41.5
Pond	2	0	2	0	2	11.3
Powerblock	2	2	0	0	0	7.5
SCA	2	0	0	0	6	15.1
Percent of Total	41.5	3.8	3.8	1.9	49.1	100.0

* Suspected cause of death was assigned based on available evidence and proximity of detection to Project infrastructure. Detections that had evidence of scavenging were assigned as “unknown” because it can’t be

determined whether the event was caused by predation or interaction with project infrastructure. Detections that were intact (i.e., no evidence of scavenging) and located in close proximity to Project infrastructure (e.g., found directly beneath overhead lines) had a suspected cause of death attributed to the respective Project component. However, it should be noted that there is substantial uncertainy associated with cause of death assignments because no events were directly observed.

Comentado [FWS2]: This blanket categorization is problematic. Other visual evidence may allow determination of a suspected cause of death despite evidence of scavenging (i.e., smudge on mirror). The presence of some scavenging should lead to an automatic categorization. Small levels of scavenging can be easily distinguished as not the cause of death (i.e., arthropod scavenging and minimal raven scavenging). Also, other indicators of the cause of mortality should also be considered (dust smudges, species identification, etc). This should not be a blanket categorization.

Feather Spot Detections

Seventeen (32.1%) of the 53 detections consisted only of feather spots. Along the fence, nine detections (81.8%) were feather spots. Six detections (27.3%) along gen-tie and distribution lines and road were feather spots. One detection (16.7%) at the evaporation ponds and one detaction (12.5%) at the SCAs were feather spots. None of the detections at power blocks were feather spots.

Detections of Stranded Birds

Comentado [FWS3]: Who detected the stranded birds?

Two birds were detected during the reporting period that were alive and uninjured but unable to take flight. A common loon was discovered on March 31 beneath the SCAs on the east side of Unit 1 near the evaporation ponds. A second common loon was detected on April 20 beneath the SCAs on the west side of Unit 1, north of the power block. Both of these birds were examined for injuries and when none were observed, were successfully released at Lake Tamarisk. Both individuals are included in this report (including the fatality analysis) as detections, resulting in a conservative estimate of fatalities.

Comentado [FWS4]: This is a good practice, since survival from the stranding is not guaranteed, even when the birds are released successfully.

Summary of Bat Detections

No bats were detected during the spring 2015 season.

Carcass Persistence Trials

Based on carcass persistence data from the spring 2015 season, 64 survival models were compared for relative quality using the corrected AICc score, as suggested in Huso (2010). The AICc score provides a relative measure of model fit and parsimony among a selection of candidate models. Carcass size is a potentially important variable, as larger carcasses tend to persist longer and may be more likely to leave feather spots which persist for long durations, whereas smaller carcasses may be more likely to be completely removed.

The model with lowest AICc is typically chosen as the "best" model relative to other models tested; however, any model within two AICc points of the best model is considered competitive with the best model (Burnham and Anderson 2004). The top six models had ΔAICc values <2. Ultimately, the loglogistic model that included an effect of carcass size was chosen as the most parsimonious of the top models. The chosen model predicted that 42.4% of small carcasses, 72.4% of medium carcasses, and 84.5% of large carcasses persisted for a standard 7-day search interval. Mean removal time for small carcasses was 2.0 days, for medium carcasses was 7.3 days, and for large carcasses was 14.6 days.

Searcher Efficiency Trials

During the 2015 spring season, a total of 60 searcher efficiency trials (30 small, 20 medium, and 10 large birds) were placed at the Project. Overall, 19 trials were placed in the SCAs, eight trials were placed along perimeter fences (inner and outer perimeters), and three trials were placed at power blocks (along perimeter and beneath ACC units). Thirteen trials were placed along the gen-tie and 17 were placed along the distribution lines. Fifty-five trials were available to be found, and five trials disappeared before the searcher efficiency trial began (two in the SCAs, two along the fence, and one along the gen-tie line).

In the SCAs, the null model was chosen as the best model to estimate searcher efficiency. Searcher efficiency rate in the SCAs was 92.3% (24 found of 26 available to be found) and was similar across carcass size classes. Along overhead lines searcher effiency was 42.9% for small birds, 100% for medium birds, and 100% for large birds (21 found of 29 available to be found).

Fatality Estimates

Fatality estimates were calculated separately for each component (SCAs, power blocks, fence, evaporation ponds, and overhead lines/road). Ultimately, one detection was excluded from the analysis because it was estimated to be older than the 7-day search interval (Huso 2010), and five detections were excluded because they were found outside standardized search areas. Only one of the 18

Comentado [FWS5]: Are these included in carcass summary? Excluded birds should still be included in the report. Also, age of a carcass can be quite subjective, so if there is any doubt or the age is uncertain, the carcass should be included in the analysis. This is particularly true when the search interval is longer and the weather conditions are hot and dry.

detections that were found incidentally was in a standardized search area, so 17 incidental detections were excluded from the fatality analysis.

During spring 2015, there were an estimated total 234 fatalities (90% confidence interval [CI]: 124 – 430) at the Project. Of these, 55 fatalities (23.4%) were estimated for the SCAs, 44 fatalities (18.6%) were estimated for the fence, 9 fatalities (4.0%) were estimated for evaporation ponds, 5 fatalities (2.2%) were estimated for power blocks, and 121 fatalities (51.8%; 90% CI: 32 - 307) were estimated for the gen-tie and distribution lines and project road. An estimated 113 (90% CI: 60 – 188) fatalities (0.065/acre, 0.434/MW) occurred for all components associated with each solar unit (SCAs, power block, evaporation ponds, and along the perimeter fence, combined). A complete list of estimates for each Project component and carcass size class with confidence intervals is presented in Appendix B.

DISCUSSION

The 2015 spring season represented the first season of standardized monitoring at Genesis per the BBCS. Searcher efficiency trials and carcass removal trials were conducted concurrently at the SCAs, power blocks, fencelines, and along the gen-tie and distribution lines. Data from these trials were used to produce fatality estimates adjusted for searcher efficiency and carcass persistence bias. Although these estimates were produced from a statistically robust sample, only limited inference may be drawn from a single season of data. These results should be considered preliminary because estimating carcass persistence, searcher efficiency, and adjusted numbers of fatalities within each season represents information based on a limited sample size. As more data are collected throughout the monitoring year (and additional quality assurance/quality control measures occur, for example characterizing feather spots to species or size class), data from all seasons may be pooled. At that time, data will be tested for seasonal differences retrospectively, but because seasonal estimates will be produced from the much larger annual data set, they may differ from what is reported here because they are based on a larger, more informative sample.

Comentado [FWS6]: This is counter-intuitive. If there are inadequate samples to give a seasonal estimate for searcher efficiency, how will this be possible from the complete annual dataset. The number of carcasses should probably be increased based on a power analysis, so that seasonal estimates can be completed.

Carcass Persistence and Searcher Efficiency Trials

The degree to which carcasses persist on the landscape depends on a variety of factors reflecting seasonal and inter-annual variation in habitat, climate, and the scavenger community. The composition and activity patterns of the scavenger community often vary seasonally as birds migrate, new juvenile birds and mammals join the local population, and mammalian scavengers variably hibernate or estivate. The scavenger community may also vary substantially from year to year because of variation in annual reproduction and survival related to changes in landscape condition. Climatic conditions that vary seasonally and annually also may contribute to variation in carcass decay and removal rates due to variation in temperatures, solar insolation, wind patterns, and the frequency of flooding events. Thus, rates of carcass persistence reported here should be interpreted cautiously as they may change over the coming months.

Searcher efficiency was influenced by carcass size, but it is not yet clear if there may be an effect of habitat visibility class due to limited sample sizes. In the SCAs, searcher efficiency was high regardless of carcass size and this is likely influenced by the limited vegetation cover beneath solar troughs. Beneath overhead lines outside the Project fence vegetation cover is higher, but our analysis did not support the hypothesis that visibility class is a factor in searcher efficiency along the lines. Carcass size influenced searcher efficiency, but was relatively high over all carcass size classes (72.4%).

Searcher efficiency trials for this Project will be repeated seasonally. The desert landscape in which this Project is located generally changes little with the seasons, save for brief periods following winter and spring rains when floods may occur and blooming plants may flourish. A recent meta-analysis involving data from more than 70 wind-energy projects suggested that including habitat visibility class as a predictive variable generally eliminated any otherwise apparent seasonal effects on searcher efficiency (Smallwood 2013). Further, the possibility exists that searcher efficiency varies seasonally in some cover types but not others. Data from searcher efficiency trials conducted over the coming seasons will therefore continue to be tested for effects of habitat visibility class rather than effects of season.

Distribution of Fatalities and Fatality Estimates

The number of detections was highest during the middle of the spring monitoring period, and decreased at the end of May. The peak in number of detections on April 24 may have been influenced by weather conditions the preceding night. Winds were recorded from the southwest ranging from 20-30 mph from approximately 2000 hrs on April 23 to 1600 hrs on April 24, and were associated with changing cloud cover (Weather Underground, Blythe, CA).

Detections attributed to an unknown cause accounted for approximately 50% of all detections during the 2015 spring season, and the distribution of the unknown cause detections varied by project component with 81.8% occurring in association with the perimeter fence. Of the 11 detections made along the fence, 81.8% were feather spots. Determining a cause of mortality from a feather spot is challenging because there is rarely visible evidence available on which to determine a cause of death. Thus, feather spots with an unknown cause of mortality could be encountered anywhere birds occur, and an unknown cause of a sizeable proportion of the carcasses is not unique to the Project. Further, the large proportion of feather spots (32%) among the detections for the Project as a whole may inflate the fatality estimate when unknown cause detections are included based on the potential for multiple feather spots resulting from one fatality, feather spots resulting from predation not associated with the facility, or other causes.

Comentado [FWS7]: I don't agree with this statement. This is unknown. Feather spots may be more mobile, but as far as I know there have been no studies on whether they "multiply" and cause bias. If there has, please provide a reference. It is possible that feather spots could accumulate along fences, but in general, they are just as likely to migrate into a survey area as they are to leave. If this is a significant problem, then I recommend shorter search intervals and more complete coverage of the project site.

ECOLOGICAL CONSULTING

Overview and Background

A Bird Fatality Monitoring Plan (Plan) is being implemented for the Desert Sunlight Solar Farm, located in Riverside County, California. Specific objectives of the Plan include (A. Birckey, pers. comm.. 5/23/2014):

1. Estimate the overall annual avian mortality rate associated with the facility. This estimate should include mortality associated with all the features of the project that are likely to result in injury and mortality (e.g., fences, ponds, solar panels, elevated solar flux).

2. Determine which species are impacted at the facility during daylight hours and which species are being impacted after nightfall.

3. Determine whether there is spatial differentiation within the solar field in the rates of mortality between species of birds (i.e, panels on the edge of the field vs. interior of the field).

In order to meet these objectives information is needed regarding seasonal differences in mortality rates as well as taxonomic-specific risk factors and rates. In addition, mortality estimates need to be adjusted to address carcass persistence as well as searcher efficiency and the associated temporal fluctuation in these factors.

This document describes the methodology and results related to a full year of Carcass Persistence Trials. Trial dates were as follows: Round 1 -- 7 May 2014 through 22 June 2014, Round 2 – 14 August 2014 through 9 December 2014, Round 3 – 16 December 2014 through 21 January 2015, Round 4 – 27 March 2015 through 18 May 2015. This methodology incorporates agency comments and feedback received from draft copies of the Project's Plan.

Methods

For each Round, thirty non-native bird species of three different size classes (ten of each) were randomly distributed within the Sample Area. A remote trail camera accompanied each placement and was used, in conjunction with ground-based monitoring, to determine: cause of removal (scavenger species or abiotic factor), date of removal and time of removal. Cautionary measures (described below) were implemented to minimize scavenger bias and avoid scavenger swamping. Rounds 1, 3, and 4 trial monitoring consisted of a 30-day period for each carcass placement. During the assessment period each trial specimen was classified into one of the following categories based its physical persistence and detectability:

Intact: Whole and un-scavenged other than by insects

Evidence of Scavenging: Carcass present but some feathers or flesh removed

Disarticulated: Carcass present, but separated into pieces. Flesh or bones still remain.

Feather Spot: Carcass scavenged and removed, but ten or more feathers remain to qualify as a detectable fatality

Removed: Not enough remains to be considered a detectable fatality

After reviewing the results of Round 1, we decided to employ a slightly different approach with our Round 2 carcasses. As will be discussed in the results section (below), 30 days post-placement during Round 1, there were still carcasses present and wholly intact. To explore just how long a carcass may persistence in this environment, Round 2 was conducted in exactly the same manner as Round 1, but instead of collecting carcasses at the conclusion of a 30-day period, we left them in place and monitored them on a less frequent schedule than during the first 30 days of the Round.

Randomization of Carcass Locations

At the time that these trials were initiated, the Plan proposed a distance-sampling strategy that is based on the assumption that avian fatalities are random within the Sample Area. The placement of trial specimens for Carcass Persistence Trials was based on this same assumption and a spatially-balanced routine was used to randomize the trial specimens within the 2,097 acre Sample Area. This routine was performed in a GIS and created a random sample which created an inclusion probability for each project component of interest including: solar modules and perimeter fence. This inclusion probability was created based on the relative area of each component within the Sample Area. In the case of the linear perimeter fence, an interior buffer distance of 35 meters was applied. Using this approach, thirty carcasses -- ten of each size class -- were randomly placed within the Sample Area (Figure 2) for each trial.

Figure 1. A medium-sized trial specimen is randomly placed between solar modules within a solar array.

Carcass Placements

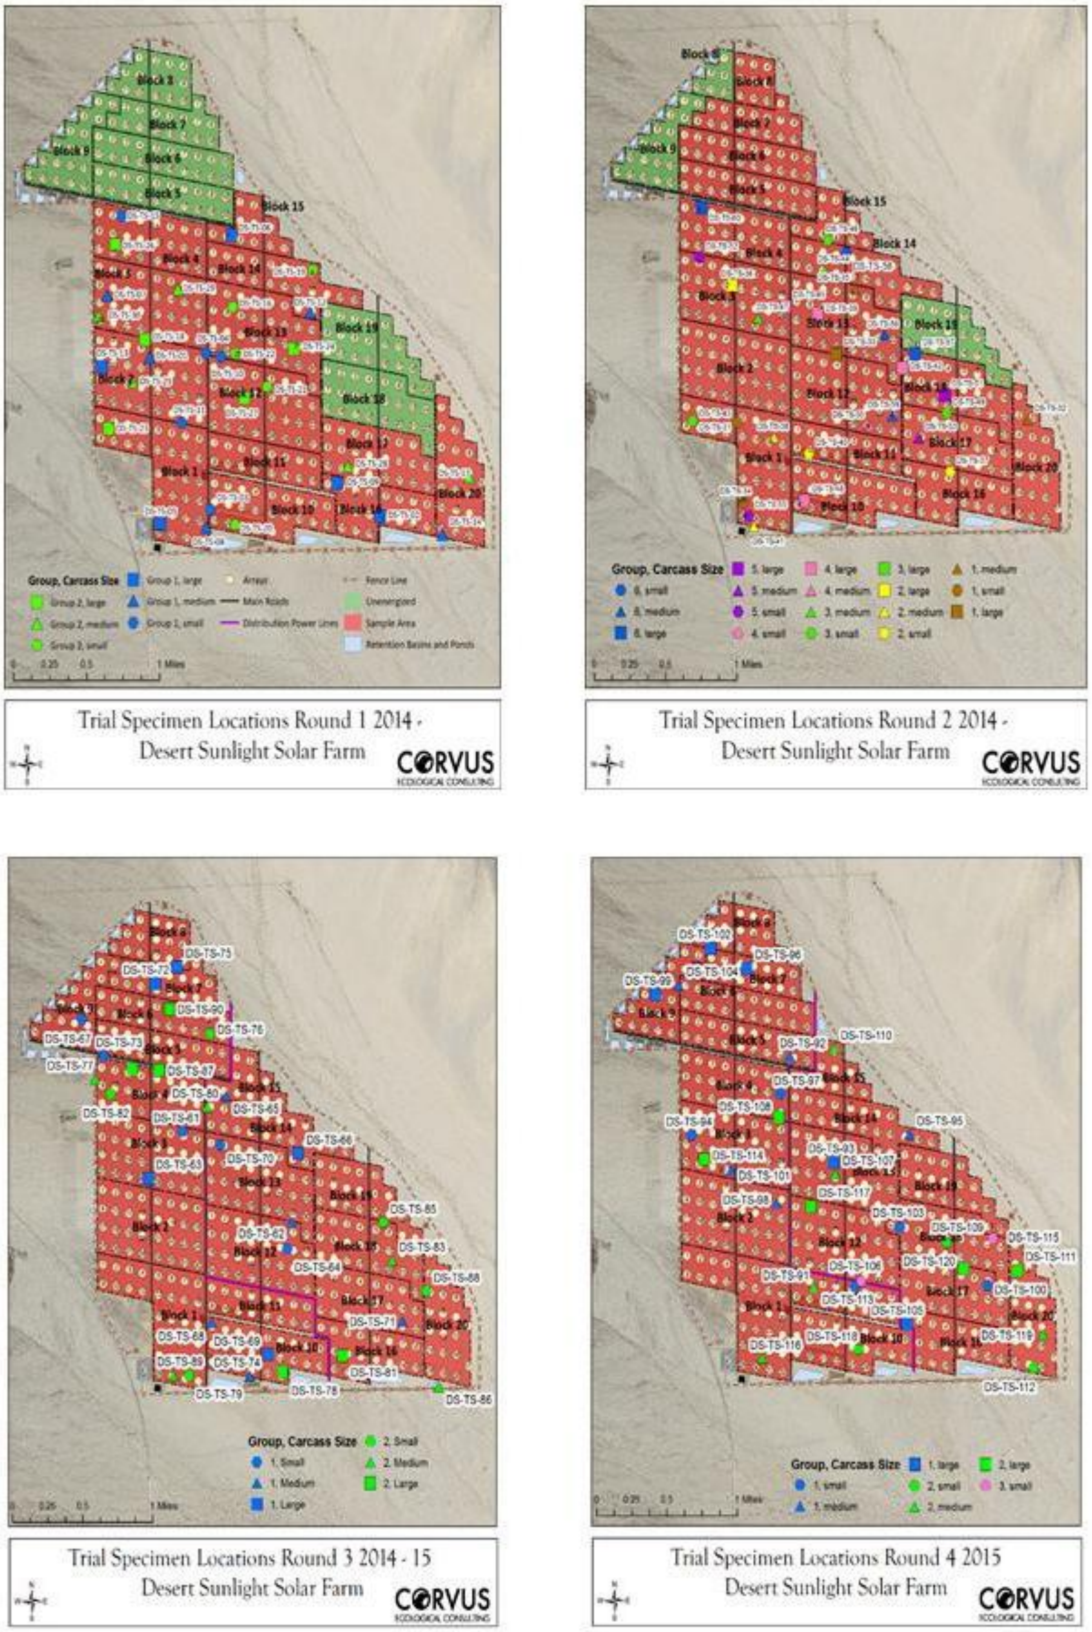
The Sample Area consisted of primary project components that will be the focus of fatality surveys including: energized solar arrays, perimeter fence and overhead power lines. Other project areas, such as retention basins, onsite sub-station and temporary water storage ponds, were not included as part of the Sample Area since focused fatality surveys will not take place within these project features. Areas of active construction, including main access roads, were excluded from the Sample Area due to the presence of uncontrollable variables that will not exist once the project enters into a fully-operational phase. It is important to note that additional panels were energized between consecutive rounds of trials so the size of the Sample Area was not consistent between all rounds. By Round 3, all panels were in place and energized, so the sample area remained consistent between the third and fourth rounds (Figure 2).

Timing of Carcass Placements

To minimize potential bias caused by scavenger swamping (Smallwood 2007, Smallwood et al. 2010) placement of trial specimens took place over a number of days. For Round 1, fifteen carcasses were placed followed by a fifteen-day period then another fifteen carcasses were placed. For Round 2, five carcasses were placed each day for 3 days followed by an eight-day gap and then another five carcasses each day for 3 days. We soon realized that given the size of the study area, 30 carcasses were not likely to have a great impact on predators. For Round 3, we placed fifteen carcasses followed by a two day gap, and then the remaining fifteen. For Round 4, we had some difficulty obtaining small trial specimen, so we placed 15 carcasses followed by a 4-day gap, and then another 13 carcasses. This final effort was shared by another contractor, West Inc., who provided data on two additional small trial specimens that were placed on 27 April 2015. Because of the asynchronous placement and the fact that we wanted each carcass to have at least 30 days of exposure, some of the carcasses were actually out for more than 30 days. For Rounds 1, 3, and 4, trial specimens were collected (if applicable) thirty to thirty-six days after their placement. As was stated above, Round 2 carcasses remained in the Study Area until they were completely removed or the next trial was set to begin.

For each round, a game camera was setup within 40-feet of each trial specimen. Game cameras were in place prior to the placement of carcasses and the initial placement of trial specimens marked the beginning of the trial period. All cameras remained in place and fully operational throughout the trial period except in a few cases where they were located along heavily traveled roads. In those cases, to protect the equipment, cameras were removed as soon as the carcass was determined to be completely removed.

Figure 2. Randomized and spatially-balanced trial specimen locations within the Sample Area Rounds 1 -4.



Game Cameras

Thirty game cameras were placed at randomized carcass locations within the Sample Area, at least five- days in advance of the trial period, in an effort to reduce the possibility that potential scavengers would form an association between cameras and a food subsidy. Cameras remained in place and operational until the end of the trial period, even after trial specimens had been removed. *Wildgame Innovations LO8* (eight megapixel) cameras were powered by external battery packs to help ensure trouble-free operation through the duration of the period.

Figure 3. Installation of a game camera within a solar array.

Trial Specimens

Trial specimens consisted of the following size classes/ species:

- Small/ House Sparrow (*Passer domesticus*)
- Medium/ Eurasian Collared-Dove (*Streptopelia decaocto*)
- Large/ Ring-necked Pheasant (*Phasianus colchicus*)

Trial specimens included only intact, fresh (i.e., estimated to be no more than 1–2 days old and not noticeably desiccated) bird carcasses that were frozen immediately following death.

All carcasses were handled with latex gloves and handling time was minimized. All trial specimens were inconspicuously marked by clipping a toe to distinguish them from unmarked fatalities and other trial specimens.
